

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE
AMERICAN CYCLOPÆDIA.

CARMONA

CARMONA (anc. *Carmo*; Moorish, *Karmunah*), a city of Spain, in the province and 20 m. N. E. of Seville, on the Carbones river; pop. in 1867, 20,074. It is a well built and handsome town, on an isolated hill commanding a magnificent view of the Andalusian valleys, and is surrounded by old and massive Moorish walls. Hardly any conspicuous remains exist of the many palaces and fountains of the Moorish era, excepting the superb ruins of the alcazar, which towers over the gate leading to Cor-

Carmona.

dova. This gate, built on Roman foundations, is celebrated for its beauty. There is a fine old Gothic church, with Pacheco's picture of the "Descent from the Cross," besides six other places of worship, nine convents, two hospitals, and a university. Woollen cloths, hats, leather, and other articles are manufactured; but the principal trade is in wine and olives, there being over 100 oil mills. The annual fair (April 25) is much resorted to.—Cæ-

CARMONTELE

sar regarded Carmona as the most strongly fortified city of Further Spain, and Roman coins and other antiquities have been found here. The place was rescued from the Moors by Ferdinand III., king of Castile and Leon, in 1247; and the castle of Carmona was subsequently used for a long time as a royal residence and refuge in times of danger.

CARMONTELE, or **Carmentel**, a French playwright and artist, born in Paris, Aug. 25, 1717, died Dec. 26, 1806.

He excelled as a writer of short plays (*proverbes*) adapted for private theatricals, and as an amateur artist. He became a great favorite in society, and was appointed reader to the duke of Orleans, as well as the director of festivities, and designer of the famous park of Monceaux, his exquisite taste being constantly called into requisition by the royal family and the fashionable classes. After the revolution he was saved from want by an amateur conferring a pension upon him of 4,000 francs, in consideration of the acquisition of his *transparentes* (pastel paintings, over 100 ft. long, which can be un-

rolled). He wrote and sketched with remarkable rapidity. His principal works are his *Proverbes dramatiques* (8 vols., Paris, 1768-'81); two additional volumes were published in 1811, and a new edition by Mme. de Genlis appeared in 1825 under the title of *Proverbes et comédies posthumes de Carmentel*, in 3 vols. He also wrote more than 25 comedies contained in his *Théâtre de campagne* (4 vols., Paris, 1775), and several novels.

CARNAC, a town of Brittany, France, in the department of Morbihan, 18 m. S. E. of Lorient, and 9 m. by road from the station of Auray, on the railway from Brest to Nantes; pop. in 1866, 2,864. It is built on an elevation not far from the sea, and contains a fine church

to which pilgrims resort annually. The celebrated Celtic or druidical monument of Carnac, the most extensive in Brittany, consists of three groups with gaps between, running parallel with the coast, stretching across the country E. to W. for nearly 7 m., and all ter-

Carnac.

minating respectively in 11 rows of unhewn stones from 10 to 22 ft. high. Originally the avenues extended continuously for several miles, but the stones are being gradually cleared away for fences and agricultural improvements, so that at present there are several detached portions, which however have the same general direction. The first group is that called *le Bal*, after an enclosure of the same name which forms a rectangular area. The second group is that of the Dolmen, so called after the large Celtic stone in the shape of a table which stands in front of it. The third and most famous group, best known under the name of Maenac, after a locality of that name where the stones reach the highest point, terminates in front of a circular enclosure within the limits of the town. According to Sir John Lubbock, who visited this locality in 1867 with Dr. Hooker, the tumuli of Carnac, like most of those of Brittany, probably belong to the stone age. The tumulus of Mont St. Michel, about 380 ft. long and 190 ft. broad, with an average height of 33 ft., was found in 1862 to contain a square chamber with numerous Celtic remains. (See *Rapport à M. le préfet du Morbihan sur les fouilles du Mont St. Michel*, by M. René Galles, 1862.) A chapel is built on the summit of this tumulus, the roof of which commands the finest view of the monuments and surrounding scenery. The best map of the relics of Carnac is in possession of the London anthropological society. There are similar relics, though on a much smaller scale, at Erdeven, about 5 m. N. W. of Carnac.—See "Prehistoric Times," by Sir John Lubbock (2d ed., London, 1869), and another recent publication, "The Stone Avenues of Carnac," by the Rev. William Collings Lukis.

CARNARVON, or **Caernarvon**, the chief town of Carnarvonshire, Wales, a parliamentary and municipal borough, situated upon the Menai strait, at the mouth of the Seiont, 55 m. W. S.

Carnarvon Castle.

W. of Liverpool; pop. in 1871, 8,512. It is the terminus of railways from Bangor on the north and Pwllheli on the south. A railway also runs 8 m. to Llanberis, the point from which excursions are made for the ascent of

Snowdon. Carnarvon is frequented in summer for sea bathing, and there is a handsome bathing establishment, and a terrace walk along the strait, terminating in a pier. The harbor admits vessels of 400 tons burden. The older and smaller part of the town is surrounded by an ancient wall. At the S. W. corner of the town is a large castle, in the tower of which Edward II., the first English prince of Wales, was born. The castle with its courtyard is a mile in circuit. Over its gateway is a statue of Edward I. Carnarvon was the site of the Roman station Segontium.

CARNARVONSHIRE, a county of Wales, forming the N. W. extremity of the mainland, bordering on Cardigan and Carnarvon bays and Menai strait; area, 579 sq. m.; pop. in 1871, 95,694. A large part of the county is a peninsula which extends S. W. into the Irish sea. The Snowdon range of mountains occupies the centre of the county. Of this range Snowdon, 3,571 ft., is the highest point in Wales. Lakes are numerous, but the only river of importance is the Conway, which separates the county from Denbighshire. Not one fortieth of the county is arable land, but it is rich in minerals. The slate quarried here is one of the most important mineral productions of Great Britain; most of it is sent for shipment to Bangor. The suspension bridge built by Telford for the Great Holyhead railway, and the tubular bridge built by Stephenson for the Chester and Holyhead railway, span the river Conway and the Menai strait.

CARNATIC, an ancient province of British India, on the E. coast of the peninsula, extending from Cape Comorin to lat. 16° N., with an average breadth of about 90 m.; area, about 50,000 sq. m.; pop. estimated at 7,000,000. The province is separated into two parts by the Eastern Ghauts, which run parallel with the coast, and which cause a considerable difference in climate between the table land and the seaboard; the latter in dry weather is the hottest part of India, the thermometer sometimes standing at 130° in the shade. The principal rivers are the Pennar, the Palar, and the Coleroon. The inhabitants are chiefly Hindoos. The Carnatic includes the cities of Madras and Pondicherry, besides the important towns of Arcot, Madura, Tanjore, Trichinopoly, Nellore, and Vellore. It originally formed the Hindoo kingdom of Carnata, and after various changes was finally included in the dominions of the nabob of Arcot; and the contentions arising from a disputed succession first brought the French and English into collision, and ended in the transfer of the Carnatic to the East India company in 1801, the reigning nabob, Azim ul-Omrah, receiving a pension equal to one fifth of the revenue, and his chief officials being provided for. The last titular nabob died in 1855, without heirs. The Carnatic is now included within the administration of the presidency of Madras. The principal occupation of the inhabitants is agriculture, the

land being held either by Brahmans, who cultivate it by hired labor, or by the farmers themselves. Rice is the chief production, of which two crops a year are raised where the facilities of irrigation are good. Cotton is raised in favorable situations, and upon the high land in the interior of the province millet, sugar, and indigo are produced.

CARNÉ. I. Louis Marcein, count de, a French author, born at Quimper, Feb. 17, 1804. He early entered the diplomatic service. In 1839 he was elected to the chamber of deputies, where he was a follower of Lamartine. He opposed the Pritchard indemnity and other measures of Guizot's foreign policy, but in 1847 accepted the presidency over the commercial department in the ministry of foreign affairs, retiring after the revolution of Feb. 24, 1848. He was elected a member of the academy in 1863. In 1869 he was defeated as an ultramontane candidate for the legislative body. His numerous publications include *Études sur l'histoire du gouvernement représentatif en France de 1789 à 1848* (2 vols., 1855), and *Études sur les fondateurs de l'unité française* (2 vols., 1848-'56).

II. Louis de, son of the preceding, born in Brittany in 1843, died there in 1870. After having finished his studies, he was admitted in 1863 to the commercial department of the ministry of foreign affairs; and his uncle, Admiral La Grandière, exciting his interest in Cochin China, he was appointed by Drouyn de Lhuys in 1865 secretary of the scientific mission to the Mekong. He distinguished himself as an explorer, and wrote *Voyage en Indo-Chine et dans l'empire chinois*, edited by his father after his death (Paris, 1872; translated into English, London, 1872).

CARNEADES, a Greek philosopher of the Skeptic school, considered as the founder of the third or new academy, born at Cyrene about 213 B. C., died in 129. Of the incidents of his life very little is known, but of his brilliant qualities as a philosopher and rhetorician there is abundant testimony in the works of classic authors. In Athens he became a student of the Stoic and Skeptic doctrines, especially those of Chrysippus, of whom he afterward became the most formidable opponent. His eloquence was considered so irresistible, his logic so forcible, that more than a century later Cicero said, "Him I would not care to challenge in debate, but would rather propitiate him, and implore his silence." It is related of him that having been sent to Rome as one of three commissioners of the Athenian commonwealth, he one day made a speech in favor of justice, and the next day one in opposition. His arguments on either side were so convincing, and seemingly unanswerable, that Cato, fearing lest the public mind should be corrupted by such an exhibition of plausible arguments for immorality and injustice as well as for morality and justice, insisted upon a speedy settlement of the diplomatic business for which Carneades had come to Rome, and his prompt dismissal from the

city. He was not an author, but transmitted his doctrines to his disciples by word of mouth, like Socrates. So far as the philosophy of Carneades is known, its substance may be condensed thus: Every perception is a certain change or movement in a sensible being, bringing to consciousness first itself, and secondly some object without. In respect to the object, the perception is either true or false; in respect to the one who perceives, either probable or improbable. There exists no test to decide on the truth or untruth of a perception, that is to say, on the relation which the perception bears to the object by which it is caused. There is no objective certainty, or guarantee that real existing things are essentially reproduced by the human perception; but whatever the relation of human perception to reality, to man himself the mere probability, the test, of which lies within the limits of his mind, is sufficient for all practical purposes. Thus much may be designated as the affirmative portion of the philosophy of Carneades; the practical portion was his criticism of the then existing philosophical system, a criticism based merely upon the supposition that the affirmations and negations of human language comprise all existing possibilities, so that if both should be refuted a *non est* would be proven. Carneades pretends to prove the non-existence of God by the following reasoning: God is either a rational and sensitive being, or he is not. If he is, then he would be subject to sensations agreeable and disagreeable, to likes and dislikes; but if so, he would be a changeable being, and, as such, liable to destruction. On the other hand, if God is not a rational and sensitive being, then he could not have been the creator of reason and sensation. Again: God is either finite or infinite. If the latter, then he would be motionless, and therefore inactive; if the former, there would be something that was more than he, because limiting him. By similar arguments he gets rid of all general ideas of morality, human rights, duties, &c. But when he seems to have destroyed everything, he suddenly turns round, concluding that all these arguments prove merely that absolute metaphysical knowledge is as unnecessary as it is impossible; that man ought to be satisfied with probabilities and expediences, which are amply sufficient to secure his well-being.

CARNEIA (Gr. *κάρνεια*), a national festival of the Spartans, celebrated in honor of Apollo, and in the Spartan month Carneios (August). The festival lasted nine days, during which the Spartans were not allowed to enter upon a hostile campaign.

CARNELIAN (Lat. *caro*, gen. *carnis*, flesh; called by the ancients *sarda*), a clear red chalcedony, one of the numerous varieties of the quartz family of minerals. (See AGATE.) It is found resembling flesh in its colors, whence its name. By exposure to the sun and baking, the colors are deepened. Together with agates, carnelians are quarried in great quantities in differ-

ent parts of India, particularly in the region of Cambay, whence the name commonly applied to them all of Cambay stones. They are also brought to the lapidary workshops at Cambay from different parts of Guzerat, to be worked up into round and flat necklaces, beads, bracelets, armbands, seals, marbles, chess men, studs, rings, &c., which give employment in their manufacture to nearly 2,000 people. Between the Bowa Gore and Bowa Abbas hills, on the plain, are small mounds, in which the stones are quarried by the Bheels of the district. They sink shafts, and excavate horizontal galleries, working underground with lamps. The stones, being brought to the surface and sorted, are purchased of the miners in the village of Ruttunpoor, by the contractor or his agents. When a considerable quantity is collected, a trench is dug in a field two feet in depth and three in breadth. In this a fire is made with the dung of goats and cows, and upon it earthen pots containing the stones are placed in rows. The fire is kept up from sunset to sunrise, when the pots are removed, and the stones piled away. These once a year are carted to Nemodra, then sent down the river in canoes to Broach, and thence in boats to Cambay. The manufacture of beads from the rough stone is thus conducted: The stones, brought to a convenient size, are chipped into a rounded form upon the point of an iron, standing inclined in the ground. Another workman then takes them, and fixing a number of equal size in wooden or bamboo clamps, rubs them on a coarse, hard polishing stone; they are then transferred to another man, who secures them in clamps, and rubs them on all their sides against a ground polishing board, smeared with a composition of emery and lac. The final polish is given by putting several hundreds or thousands of the beads into a stout leathern bag, about 2 ft. long and 10 or 12 in. in diameter, with some emery dust and the carnelian powder obtained in boring the holes through the beads. The mouth of the bag is tied up, and a flat thong is bound around its centre. Two men seated at opposite ends of a room then roll it back and forth between them, keeping up the operation from 10 to 15 days, the bag being kept moistened with water. When the beads are well polished, they are passed to the workmen who bore the holes. This is done by means of a steel drill tipped with a small diamond, the work being kept wet by water dripping upon it.—Carnelian is a common mineral in many localities in the United States, especially on Lake Superior, in Missouri, and on the upper Mississippi. It is used for numerous articles of jewelry, and is cut on a leaden plate with emery, and polished on wood with pumice stone.

CARNICER, Ramon, a Spanish composer, born at Tarrega, Oct. 24, 1789, died in Madrid, March 17, 1855. He studied music, chiefly in Barcelona, and was more than ten years leader of the orchestra in the opera there, till 1828, when

he went to Madrid, and became in 1830 professor at the conservatory of music. Between 1827 and 1845 he composed many operas, the most successful of which were *Adela de Lusignano* and *Colombo*. He also excelled in church music and in popular ballads.

CARNIOLA (Ger. *Krain*), a duchy in the Cis-leithan half of the Austro-Hungarian monarchy, bounded N. by Carinthia, N. E. by Styria, E. by Croatia, S. by Croatia and the Coastland, and W. by the Coastland; area, 3,857 sq. m.; pop. in 1870, 466,334, of whom 93 per cent. were Slovans, the remainder mostly Germans. Nearly the entire population belongs to the Catholic church, all others numbering less than 1,500. It is a mountainous region, traversed by branches of the Julian Alps, abounding in grottoes, caverns, and underground passages, and presenting many snow-capped summits, several of which are about 10,000 ft. high. It is neither so well watered nor so fertile as the neighboring districts of the empire, the only rivers of note being the Save and the Kulpa, and the lakes being mostly very small. The southern part produces fruits and a fine variety of flax; bees and silkworms are extensively reared, and in some districts wheat, barley, and the grape are largely cultivated. With minerals Carniola is richly gifted. Its famous quicksilver mines at Idria, next to Almaden in Spain the richest of Europe, once produced upward of 16,000 cwt. per annum, and still yield about 6,400 cwt. Iron, lead, coal, marble, clays, and precious stones are also found. There are manufactures of iron, steel, fine linen, woollen, flannel, worsted stockings, lace, leather, wooden ware, &c. The exports comprise several of the above articles, together with hats, glass, wax, wine, and flour; and the imports, salt, oil, coffee, sugar, tobacco, cloths, cattle, and fruit.—Carniola was subdued by the Romans at an early period, and was occupied by Slavs in the 6th century. It was Christianized in the 8th century, became a margraviate in the 10th, was afterward partly under the sway of the dukes of Austria and Carinthia, and in the 12th century was erected into a duchy. It was then held by the powerful dukes of Tyrol, until the extinction of that family in 1335, when it passed into the hands of the counts of Görz, who were succeeded by the house of Austria in 1364. By the treaty of Vienna in 1809 it was ceded to France and incorporated in the kingdom of Illyria, but restored to Austria in 1814. The Carniolan diet is composed of the *Landeshauptmann*, the prince-bishop of Laybach, and 30 delegates. Capital, Laybach.

CARNIVAL, a festival observed in most Roman Catholic countries immediately before the commencement of Lent, but celebrated with more parade in Rome and Venice than any other cities. Its name is derived from the Latin *carni vale*, farewell to meat, as from Ash Wednesday, the first day of Lent, a strict fast is observed for 40 days. Much dispute exists

as to the origin of this festival, but it has probably come down from the Saturnalia of pagan Rome, modified by the early Christians into a feast during the several days preceding the great fast of 40 days, generally supposed to have been instituted by Telesphorus, bishop of Rome, before the middle of the 2d century. The carnival appears to be most suited to the genius of the Italian people, being kept up by them with undying spirit, while in other lands it has frequently languished or fallen into neglect. The only relic of it remaining in England, or ever introduced into the English portions of North America, consists in the observance of Shrove Tuesday. In Paris the carnival takes place during the five or six weeks preceding Ash Wednesday, and is marked by the frequency of masked and fancy balls in private society, and at the various places of public amusement; such balls, to which the public is indiscriminately admitted, having been first permitted by the regent duke of Orleans. During the festivities, masks appear in the streets only on the Sunday, Monday, and Tuesday preceding Lent, and at Mi-Carême or Mid-Lent Thursday. On these days persons in disguise, many of them masked, and exhibiting all sorts of folly, parade the streets, and immense crowds in carriages, on horseback, or on foot, assemble to witness the gayeties of the scene. The carnival was prohibited in 1790, and no more celebrated until the appointment of Bonaparte as first consul. Its restoration was a cause of great joy to the Parisians, and for some years nothing could exceed the beauty and richness of the costumes displayed upon this annual festival; but it has now lost many of its charms, and the masks are comparatively few. After parading the streets, the masks repair for the night to the various masked balls of every description, which then abound in the capital. The public masked balls take place on fixed days throughout the carnival, being given at almost all the theatres. The procession of the *bœuf gras* (the fat ox) has for ages been celebrated at Paris on the Sunday and Tuesday before Lent, when the government prize ox, preceded by music, and accompanied by a numerous train of butchers fantastically dressed, is led through the streets. The ox is covered with tapestry, and his head adorned with laurel. Formerly the ox bore on his back a child, called *roi des bouchers* (king of the butchers), decorated with a blue scarf, and holding a sceptre in one hand and a sword in the other. He now follows the ox in a triumphal car, but without his sword and sceptre.—The carnival in Italy is much the same in the different cities where it is celebrated; that of Venice is by no means as brilliant as in former days, and it will be therefore sufficient to describe that of Rome. It extends over the eleven days which immediately precede Ash Wednesday, though only eight days are actually given up to its festivities, the two Sundays and Friday not being included, from

motives of religion. The festivities are held in the Corso, and the streets immediately adjoining, to which the show is confined. The Corso is about a mile long, but very narrow, being on an average only about 35 ft. broad, and lined by lofty houses, nearly all of which are built with overhanging balconies, with especial reference to this spectacle; and where permanent balconies are wanting, temporary structures of wood are frequently erected. Thus persons on opposite balconies are brought within speaking distance, or near enough to exchange bouquets and sugar-plums. The street beneath is densely filled with carriages and foot passengers, and all are brought so close together as to act and react upon each other. The sport does not last through the whole of each day, but only from about 2 o'clock till dark, during the short days of February. Pieces of brilliant cotton, cloth, or silk, red, yellow, and blue, are hung over the balconies, while innumerable streamers of the same hues flutter in the breeze. Far as the eye can reach, the balconies are crowded with spectators, many of them beautiful and gayly dressed women. The course below is thronged with two rows of carriages, moving in opposite directions and filled with gay parties; while crowds of pedestrians mingle among the vehicles, clad in every variety of costume that fancy can suggest, masked, and playing every imaginable prank within the bounds of decency. Meanwhile all engage in pelting each other far and near with flowers, bonbons, and confetti. For some time before the carnival begins flowers are brought into Rome in exhaustless profusion, costly bouquets of hot-house flowers being ranged side by side with the wild growth of the Campagna. The bonbons are not so abundant, but still are used extensively; while the confetti, which are nothing but pellets of lime about the size of a pea, are scattered in myriads, and cover those attacked from head to foot with lime dust. Every day of the masquerade the Corso becomes more crowded and more animated, till on the last the number and spirit of the masks, the skirmishes of bonbons and lime dust, and the shouts and enthusiasm of all, surpass description. Of the mass who elbow one another through the crowded streets, the greater part are in their ordinary garb, though disguises are common enough not to attract any particular notice. Among the most usual masks are punchinellos, harlequins, and pantaloons. Some of the masks carry an inflated bladder on the end of a stick, with which they deal noisy but harmless blows. Besides carriages such as are seen every day, many are put together for the occasion merely, and consist of framework resting upon wheels, and made to assume various shapes, such as ships or moving forests. Every day of the masquerade there is a race by spirited horses, but without riders. About 5 o'clock preparations begin for the running of these animals. Mounted dragoons trot up and down the Corso,

the carriages are withdrawn into by-streets, and pedestrians alone are left. Meanwhile the horses which are to run have been brought to the starting point in the piazza del Popolo. Each one is held by his groom in a showy uniform, and they are kept within bounds until the hour for starting arrives by a rope stretched across the Corso. They are goaded on in the race by metal balls full of sharp points, which are fastened to their trappings. The goal is formed by a piece of cloth suspended across the street near the Venetian palace, at the Ripresa de' Barberi, so called from Barbary horses being the original racers. At this point the judges are assembled to decide upon the race. Goethe, who visited Rome in 1788, says that carriages were then allowed to remain in the Corso, and their presence rendered it so narrow that horses often dashed themselves against the wheels and were instantly killed. Of late years, the celebration of the carnival in Rome has lost much of its ancient splendor and interest.

CARNIVORA (Lat. *caro*, gen. *carnis*, flesh, and *voro*, to eat), an order of mammals which feed upon flesh, as distinguished from the *herbivora*, or vegetable feeders. This order has been divided into various groups by different authors, some including in it the *cheiroptera* and *insectivora*, and others limiting it to the following five families, which agree in their most essential characters, viz.: *ursidæ*, or bears; *mustelidæ*, or weasels; *canidæ*, or dogs; *felidæ*, or cats; and *phocidæ*, or seals. The bears constitute the plantigrades, the seals the pinnigrades, and the other three the digitigrades, according as the whole foot or only the toes touch the ground, or as the extremities are modified into fin-like paddles. The *felidæ* are the most truly carnivorous, and constitute the type of the order; and in them the large canine teeth, sharp retractile claws, and great strength and agility indicate a special formation for the pursuit and destruction of living prey. The skeleton exhibits the modifications adapted for the manner of life in the shape of the bones, their articulations, and proportions. In the *felidæ* the spine is flexible, yet strong, with a large development of the lumbar portion; the ribs are narrow and far apart, the limbs long and affording the greatest freedom of motion, and the skull short and broad. In the weasels the spine is lengthened in accordance with the habits of these prowling creatures. In the bears the foot is placed wholly on the ground, and the shortness of the lumbar region of the spine adds to the firmness and strength of limb required in these less carnivorous animals. In the seals the posterior limbs are extended backward into two horizontal fins, the anterior also serving in addition for a limited progression on land. The cranium is remarkable for the shortness and strength of its facial or tooth-bearing portion, and for the crests and large fossæ for the accommodation of the powerful muscles of mastication; in the cats the tentorium cere-

belli is bony, evidently to protect the brain during the sudden movements of leaping upon their prey, and the whole bony structure is remarkably solid; the lower jaw is strong and short in proportion to the carnivorous propensity of the genus. The vertebræ of the neck are remarkable for the size of the first two; the dorsals and the number of ribs vary from 13 (the most common) to 16; the lumbar vertebræ, always numerous in proportion to the leaping powers, vary from 4 to 7; the sacrum is composed of several vertebræ, and in the bears is remarkably broad, for the support of the body in their frequently erect position; the tail is the longest in the most active species, as in the lion and the panther. The shoulder blade is flat and broad; the clavicle, when not entirely wanting, is quite rudimentary; the humerus is arched, short, and strong; the bones of the forearm have but little motion on each other, except in the *ursidæ*, and the ulna is generally placed behind the radius, both of them in the seals being broad and flat; the metacarpus is much larger in the digitigrades than in the plantigrades. The retractile claws of the *felidæ* are described in the article CAT, in which family they are most developed. The pelvis is short, and its bones broad and flat; the thigh bone is moderately long, and directed immediately downward, except in the seals, in which its direction is outward. The bones of the leg are generally separate; the tarsus consists of the usual five bones, but the tuberosity of the os calcis is quite long and strong; the inner metatarsal bone in the cats and dogs is merely rudimentary; in the weasels the inner toe is small, in the cats wanting, and in the plantigrades in the same range as the others; in the plantigrade foot everything is arranged for slow and steady walking, in the digitigrade for leaping and tearing, and in the pinnigrade for swimming. The muscles in this order, especially of the jaws, neck, and anterior extremities, are enormously large and powerful. In the typical carnivora, the incisor teeth are small, and placed in the intermaxillary bone; the canines, situated above, at the junction of the intermaxillaries with the superior maxillaries, are strong, long, and cutting, slightly curved, and admirably adapted for tearing their prey; the cheek teeth have cutting edges, the lower shutting within the upper like the blades of scissors, and are provided with sharp triangular processes; the teeth are arranged in a short space, and their action is rendered more efficacious by the shortness of the whole jaw, and by the simple hinge-like motion of the lower jaw; in the seals the canines are much smaller, but the cheek teeth are furnished with numerous sharp points for the purpose of holding the slippery and sealy fish upon which they feed; in the bears the jaws are much longer, and the molars are flattened and tubercular, indicating the far less carnivorous propensities of this family. The carnivora, in proportion to their approach to the typical *felidæ*, whose food when swallowed

is so like their own tissues that it is ready for speedy assimilation, have a short intestinal canal; in the lion it is but three times the length of the body, and has very few internal folds, and a very small cæcum, while in man it is five times as long, in the horse 10 times, in the sheep 28 times; such is the relation between the organs, that the form of the teeth indicates the character of the intestinal canal, the armature of the feet, the mode of progression, and very nearly the habits and mode of life of an animal. The lobes of the liver vary in number from four in the badger to eight in the lynx, without any apparent physiological reason; the hepatic ducts correspond in number to the lobes, and the common duct, before it enters the intestinal cavity, frequently receives a pancreatic duct; the gall bladder is always present, and in the *ursidæ* is of great size; the pancreas and spleen do not differ, except in form, from these organs in other mammals; the chyle is so noted for its opacity and whiteness, that the discovery of the lacteals was made in these animals long before they were seen in man. The carnivora belong to the sub-class *gyrencephala* of Owen, in which the cerebral hemispheres are the largest developed (except in man), extending over a portion of the cerebellum and the olfactory lobes; in this arrangement they are next to the *quadrumana* or monkeys; the hemispheres have well marked though simple convolutions. The organs of sense are well developed; in the diurnal carnivora the pupil is round; in the cats it is elongated vertically, and in a very bright light almost linear, but it is round in the dark, causing the brilliant *tape-tum* of the posterior arch of the choroid to appear like a ball of fire; the large size of the mastoid process, communicating with the cavity of the tympanum, indicates considerable acuteness of the sense of hearing, necessary for animals seeking their prey during the stillness of night; the sense of smell, especially in the *canidæ*, is very acute, and the pituitary membrane is extended greatly by means of the complicated convolutions of the turbinated bones; the sense of taste is probably not very acute, and the tongue of the cats is covered in its middle portion with horny spines, well calculated to tear the flesh from bones. The kidneys in some families, as in the bears and seals, are much subdivided, resembling a bunch of grapes; in the cats the divisions are hardly perceptible. In the civets and allied genera there are glandular follicles, which secrete a peculiar odorous substance, sometimes exceedingly fetid; the glands are usually situated near the anus, and the excretory ducts open between the rectum and the genital organs. The testes are generally pendulous and external, but in the seals they remain permanently within the abdominal cavity; the vesiculæ seminales do not exist, but organs resembling the prostate and Cowper's glands are generally found; in almost all there is a bone in the penis, the hyæna forming an exception, it is said; the teats are abdomi-

nal, ranging from four in the lioness to ten in the bitch; the placenta is zonular, surrounding the fetus.—The geographical distribution of the carnivora is very extensive, but the largest and most destructive species are confined to the tropics of the old world; the tiger is limited to Asia, the lion to Asia and Africa, the cougar to America; the largest bears frequent the arctic regions, and the largest seals the antarctic waters. The carnivora fulfil an important purpose in the economy of nature, by keeping in check the increase of the herbivorous animals, whose countless numbers would otherwise destroy vegetation, and thus cause their own and a general destruction.—Cuvier associated under the name *carnassiers* the cheiroptera, insectivora, carnivora, and marsupials; excluding the latter, which form a sub-class by themselves, many more recent authors adopt a somewhat similar classification. Prof. Agassiz, in his "Essay on Classification," divides mammals into three orders, *marsupialia*, *herbivora*, and *carnivora*, the last the highest in the scale. Prof. Owen divides his sub-class *gyrencephala* into the three primary divisions of *mutilata* (including the cetaceans), *ungulata* (pachyderms and ruminants), and *unguiculata* (carnivora and the monkeys), the last being the highest in development; in the *unguiculata* the sense of touch is more highly developed through the greater number and mobility of the digits, and the smaller extent of covering with horny matter; in the carnivora he places the digitigrades at the head, then the plantigrades, and lastly the pinnigrades; and among the digitigrades the *felidæ* are placed highest, whose retractile claws and long and narrow hind foot make them the most perfect and typical form of the carnivora.

CARNOCHAN, John Murray, an American surgeon, born in Savannah, Ga., in 1817. His father, who was a Scotchman, sent him when a boy to Edinburgh. After graduating in the high school and university of that city, he returned to the United States, and entered the office of Dr. Valentine Mott of New York as a student of medicine. After taking his degree, he again visited Europe, and passed several years in attendance upon the clinical lectures of Paris, London, and Edinburgh. In 1847 he commenced the practice of his profession in New York. In 1851 he was appointed surgeon-in-chief of the New York state emigrant hospital. In 1852 he successfully treated a case of *elephantiasis Arabum* by ligature of the femoral artery. In the same year he performed the operation of amputating the entire lower jaw, with disarticulation of both condyles. In 1854 he excised the entire ulna, saving the arm, with its functions unimpaired; and subsequently, in another case, removed the entire radius with equal success. In 1856 he performed for the first time one of the most startling and original operations on record, in excising for neuralgia the entire trunk of the second branch of the fifth pair of nerves, from

the infra-orbital foramen, as far as the *foramen rotundum* at the base of the skull. Amputation at the hip joint he has performed several times; once in 1864, after the battle of Spottsylvania. Among his more recent operations are the ligature of both common carotid arteries in a case of elephantiasis of the head, neck, and face; the ligature of the common carotid on one side, and of the external carotid on the other, for hypertrophy of the tongue; and the tying of the femoral artery for varicose veins of the leg and thigh. He has also been successful in the removal of large ovarian tumors. From 1851 to 1863 Dr. Carnochan was professor of the principles and operations of surgery in the New York medical college, and published his lectures on partial amputations of the foot, lithotomy, and lithotrity, and also a "Treatise on Congenital Dislocations" (New York, 1850), and "Contributions to Operative Surgery" (Philadelphia). He has translated Sedillot's *Traité de médecine opératoire, bandages et appareils*, and Karl Rokitan-sky's *Handbuch der pathologischen Anatomie*. From 1870 to 1872 he was health officer of the port of New York.

CARNOT. I. Lazare Nicolas Marguerite, a French statesman and tactician, born at Nolay, Burgundy, May 13, 1753, died in Magdeburg, Prussia, Aug. 2, 1823. When only 18 he was made a second lieutenant of engineers; two years later he was first lieutenant; in 1783 captain, in which year he wrote an essay on aerial navigation and a eulogy of Vauban, which brought him into controversy with Gen. Montalembert, who caused him to be arrested and confined in the Bastille. He had also published about the same time an *Essai sur les machines*, in which he demonstrated a new theorem upon loss of motive power, which Arago declared to be one of the greatest and most useful discoveries of the age. He did not at first actively participate in the revolution, although he submitted to the national assembly a memoir with a view to a restoration of the finances. In 1791 he was elected deputy to the legislative assembly by the department of Pas-de-Calais, and devoted himself assiduously to his new duties. As a member of the committee on military affairs, he greatly contributed to the adoption of the decree ordering a large addition of forces to the national guard; and it was in accordance with his report that, for want of muskets, the new guards were armed with pikes. The efficacy of these weapons was soon tried, Aug. 10, 1792, in the assault against the Tuileries. In the following month he was elected to the convention, and was present on the trial of Louis XVI.; his vote was recorded in these words: "In my opinion, both justice and good policy require the death of Louis; but I must confess that never a duty so heavily weighed on my heart as the one that is now incumbent upon me." He was neither a Girondist nor a montagnard, but upon the fall of the former party he did not hesitate to side with the lat-

ter. In August, 1793, he entered the committee of public safety. The armies were demoralized; there were no funds, no provisions; enemies had invaded France in every direction; the insurgent Vendéans were successful; the city of Lyons kept at bay the besieging army; and Toulon had been just delivered into the hands of the English. Carnot went boldly to work, and succeeded so well that his fellow citizens declared emphatically that he had "organized victory." He proved himself to be not only a skilful administrator, but a strategist of the highest ability. The 14 armies created by the rising *en masse* of the nation cooperated under his orders in the execution of a well devised plan; they were placed under the command of new generals able to understand the projects of the directing mind, and defeats were soon succeeded by brilliant victories. Carnot sometimes repaired in person to the weakest or most exposed point to watch the operations, and to inspire the troops with his ardor and confidence. A victory was won at Wattignies, which forced the prince of Coburg to retreat; Toulon was retaken from the English; the Vendéans were defeated and almost destroyed; and the Austrian army was expelled from France. As a member of the committee of public safety, Carnot, being entirely absorbed in the performance of his especial duties, left the interior administration in the hands of his colleagues, and was scarcely aware of the atrocities which were perpetrated in the name of the committee. Thus he did not participate in the revolution of the 9th Thermidor; but after the fall of Robespierre he energetically defended his colleagues, Collot-d'Herbois, Billaud-Varenes, and Barère, charged with being the accomplices of the man in whose overthrow they had been instrumental. Carnot was on the point of being arrested, and was only saved by Bourdon de l'Oise exclaiming, "This is the man who has organized victory." After the 1st Prairial, 1795, he was again threatened with impeachment, and was obliged to leave the committee and give up the management of war affairs, which he had held for nearly two years. On the establishment of the directory, he was elected representative by 14 departments at once, and took his seat in the council of 500. Being appointed one of the five directors, he resumed his previous office and planned the admirable campaign of 1796, the success of which was secured in Italy by Bonaparte. After the *coup d'état* of the 18th Fructidor, Carnot was condemned to transportation, but escaped to Switzerland, and afterward to Germany, where he wrote a memoir to vindicate his conduct. After the 18th Brumaire he returned to France, and was appointed minister of war in 1800; but being unable to agree with Bonaparte, he resigned. In 1802 he was elected to the tribunate, where he voted against the establishment of the legion of honor, the consulate for life, and espe-

cially the empire. On the suppression of the tribunate he retired to private life, and resumed his scientific pursuits. But in January, 1814, he addressed a letter to Napoleon, proffering his services: "I staid away as long as you were prosperous; now that misfortune has come, I do not hesitate to place at your disposal what little ability I may still possess." Napoleon at once intrusted him with the command of Antwerp. For years the supreme director of military affairs, he had gained no advancement in the army, and was still merely a major. Napoleon had to promote him to the rank of general, passing him through all the intermediate degrees at once. He defended Antwerp until the treaty of Paris, April, 1814, and returned to the capital, where he published a *Mémoire au roi*, full of liberal opinions and wise advice. On Napoleon's return from Elba, he appointed Carnot minister of the interior, which post he held for three months, during which he received the title of count of the empire, but never bore it. After the rout of Waterloo he almost alone preserved his self-possession, and suggested energetic measures, which were not adopted. "I have known you too late," said Napoleon on his departure. A member of the provisional government, his honesty was not a match for Fouché's shrewdness. On the second restoration he was again outlawed, and retired to Warsaw, then repaired to Madgeburg, where he died. His writings are numerous; besides his various political papers, he left disquisitions of great interest on several points of science, especially on fortification. A biography of Carnot was published by D. F. Arago (Paris, 1837). **II. Lazare Hippolyte**, a French statesman, son of the preceding, born at St. Omer, April 6, 1801. He was of liberal opinions, became a disciple of St. Simon, and wrote the *Exposition générale de la doctrine Saint Simonienne*, the authorship of which was, with his consent, ascribed to Bazard. But as soon as St. Simonism assumed the form of a religious creed, Carnot parted with his friends, and became a journalist, and the chief editor of the *Revue encyclopédique*. He was also intrusted with the publication of Grégoire's and Barère's *Mémoires*. He was elected to the chamber of deputies in 1839, and reelected in 1842 and 1846. After the revolution of February, 1848, he was minister of public instruction till July 5, and improved the condition of the teachers, rendered the normal schools free, and established free lectures. In 1848 he was elected to the constituent, and on March 10, 1850, to the legislative assembly. After the *coup d'état* of Dec. 2, 1851, he left France; during his absence he was elected a member of the *corps législatif*, but refused to take the oath. He was reelected in 1857, but again refused to serve. In 1863 he was elected from Paris, and took his seat. He was again a candidate in 1869, but was defeated by Gambetta. In 1861 he commenced the publication of *Mémoires sur Carnot, par son fils*.

CARNUNTUM, an ancient Celtic town in the N. part of Pannonia, on the Danube, near where Hainburg now stands, 26 m. E. of Vienna. It was an important military pass under the Romans, who made it at one time a station for their fleet on the Danube, and raised it to the position of a *municipium* according to some inscriptions, of a colony according to others. During the wars with the Marcomanni and Quadi it was for three years the residence of Marcus Aurelius, who here composed a part of his "Meditations." It was destroyed by the Germans in the 4th century, was afterward rebuilt, became once more a Roman military station, and was finally destroyed during the wars with the Magyars in the middle ages. Its remains are very extensive.

CAROLAN, or **O'Carolan**, **Turlough**, an Irish bard, born in the county of Westmeath in 1670, died in 1738. Having lost his sight when a child, he remained blind for the rest of his life; but having learned to play on the harp, he became famous for his musical and poetical genius, and is still remembered as the last and greatest of the Irish bards.

CAROLINA. See **NORTH CAROLINA**, and **SOUTH CAROLINA**.

CAROLINA MARIA, queen of Naples, daughter of the emperor Francis I. of Austria and Maria Theresa, born in Vienna, Aug. 13, 1752, died at Schönbrunn, Sept. 8, 1814. In 1768 she was married to Ferdinand IV., king of Naples, over whom she exercised great influence, which led to fatal results, especially when, in 1784, she prevailed upon the king to appoint her favorite Joseph Acton prime minister. A great share of the odium of Acton's unwise measures fell upon the queen. In 1798 Ferdinand, at the instigation of Carolina, declared war against the French republic; but after the defeat of the Austrian army under Mack, the French marched upon Naples, and the royal family were compelled to fly to Sicily, and to put themselves under British protection. Cardinal Ruffo's agitation in Calabria against the French and the Neapolitan republicans permitted the king to return to Naples in 1799; but here new intrigues were opened by Carolina, who on this occasion had the pernicious assistance of Lady Hamilton. In 1805 Carolina joined the coalition against Napoleon, but notwithstanding the assistance given to Naples by Russia and England, she and her husband were again expelled from their dominions. She went to Vienna in 1811, and died before the restoration of Ferdinand IV. to the throne. She was notoriously ambitious of political power, which, however, she was unable to manage, although possessed of some ability.

CAROLINE. **I.** An E. county of Maryland, bordering on Delaware, intersected by the Choptank and Marshy Hope rivers, and bounded N. E. by Tuckahoe creek; area, 300 sq. m.; pop. in 1870, 12,101, of whom 3,758 were colored. The surface is flat and the soil sandy. The Maryland and Delaware railroad passes

through the N. part, and the Dorchester and Delaware railroad touches the S. E. corner. The chief productions in 1870 were 130,728 bushels of wheat, 342,971 of Indian corn, 37,948 of oats, 27,302 of Irish and 17,141 of sweet potatoes, 93,591 lbs. of butter, and 9,397 of wool. There were 2,155 horses, 2,283 milch cows, 3,126 other cattle, 2,826 sheep, and 6,672 swine. Capital, Denton. **II.** An E. county of Virginia, bounded N. by the Rappahannock, and intersected by the Mattaponi; area, 480 sq. m.; pop. in 1870, 15,128, of whom 8,038 were colored. The surface is diversified, and the soil of the river bottoms is good. The Richmond, Fredericksburg, and Potomac railroad passes through it. The chief productions in 1870 were 63,462 bushels of wheat, 214,968 of Indian corn, 30,194 of oats, and 417,848 lbs. of tobacco. There were 1,203 horses, 1,733 milch cows, 2,129 other cattle, 1,900 sheep, and 4,607 swine. Capital, Bowling Green.

CAROLINE AMELIA AUGUSTA, queen of England, daughter of Duke Charles William Ferdinand of Brunswick and the princess Augusta of England, born May 17, 1768, died Aug. 7, 1821. In 1795 she married her cousin, the prince of Wales, but in the ensuing year, after she had borne him a daughter (Charlotte), the prince, who had married her reluctantly, separated from her, and Caroline retired to a residence at Blackheath. Looked upon as the victim of a profligate husband, her position excited much sympathy from the people at large, but at the same time subjected her to serious charges on the part of her enemies. In 1808 George III. instituted an inquiry into her conduct, which absolved her from any positive dereliction of duty, but without acquitting her of improprieties of conduct. In 1814 she received permission to visit her native town and to travel in Italy and Greece, and subsequently resided chiefly in a villa on the lake of Como. Her relations with Bergami, an Italian connected with her household, who accompanied her in her travels, gave rise to a new series of rumors disparaging to her honor. On Jan. 29, 1820, her husband ascended the throne as George IV., when a pension of £50,000 was offered her on condition that she should never return to England. She rejected this offer, and arrived in England in June of the same year, the people, who never withdrew their sympathies from Caroline, receiving her with enthusiasm. A charge of adultery was brought against her by the king before the house of lords, which, as partisan feelings were blended with the intrinsic interest of the case, created the greatest excitement in England. The house of lords, by a majority of 108 against 99, passed a bill of pains and penalties intended to apply to her case; but public opinion was so strongly in her favor that the prosecution was abandoned by the government. Brougham, who was her counsel, hinted significantly that if the charge was pressed the defence could prove the marriage of the king with Mrs.

Fitzherbert, which by the law would have excluded him from the throne. The queen remained in undisputed possession of her rank and title. She, however, was deeply affected at the result of the trial, and the moral shock received on this occasion accelerated her death. The humiliation of seeing the doors of Westminster abbey shut against her, when in July, 1821, she presented herself to attend the coronation of George IV., was the last blow dealt to her before she died. Her funeral gave rise to disturbances at London and Brunswick, the people attributing her death to her opponents.

CAROLINE ISLANDS, or **New Philippines**, an archipelago of Oceania, between the Philippines, the Ladrões, the Marshall islands, and Papua. They lie between lat. 3° and 12° N. and lon. 135° and 165° E.; area, 1,000 sq. m.; pop. about 28,000. They are divided into numerous groups. The westernmost of these, the Pelew, consists of seven large and a number of small islands, all of coralline formation. They are generally flat, and afford no secure anchorage. N. E. of these is the group of Yap, the principal island of which is mountainous and rich in precious metals. The islands of Egoi, resembling the Pelew in surface and formation, lie E. of Yap; they are fertile and partly inhabited. Other groups are the Swede islands, the Lütke, and the Seniavin islands. The easternmost island, called Ualan, is 24 m. in circumference, and has abundant supplies of water, fruit, and fish. The climate is mild and agreeable. The inhabitants, most of whom are of the Malay race, are generally fishermen, and make excellent sailors.—The Carolines were discovered in 1543 by Lopez de Villalobos, and were named in honor of Charles V. Nominally they belong to Spain and form part of the government of the Philippines, but they have no Spanish settlements.

CAROLINE MATILDA, queen of Denmark, daughter of Frederick Lewis, prince of Wales, and sister of George III. of England, born July 22, 1751, died at Celle, May 10, 1775. She married in 1766 Christian VII., king of Denmark, and in 1768 became mother of Frederick VI. She endeared herself to all around her, excepting the queen dowager, Sophia Magdalen, and Juliana Maria, the king's stepmother, who were jealous of her influence, and treated her with marked hostility. Their dislike to the young queen assumed a still more formidable character when Struensee, the physician and special favorite of the queen, rose to supreme power in Denmark, and in concert with his royal mistress acted with the liberal party, while the queen dowager and Juliana Maria were partisans of the old Danish aristocracy. At the same time grave imputations were cast by them upon the queen's honor. In 1771 she was delivered of a daughter; and her enemies, calling attention to the long illness and feebleness of the king, attributed the child to the illicit connection with Struensee. The ruin of the queen and her favorite was re-

solved upon by the queen dowager and her party, and on the night of Jan. 16, 1772, during a ball at the court, the agents of the queen dowager's party so wrought upon the fears of the weak Christian as to induce him to sign orders for the arrest of the queen, her favorite, and several of their partisans, and to appoint their most violent enemies to the principal offices of state. Struensee and the queen were immediately taken into custody. The minister and his friend Brandt were sentenced to death, and Caroline with her little daughter (the future duchess of Augustenburg), barely escaping the same fate, were consigned to Kronborg castle. But for Lord Keith, the British minister at Copenhagen, more stringent measures would have been taken against her; as it was, a separation from her husband King Christian (who by his semi-idiotic condition had long since ceased to possess any personal influence) was agreed upon, and Celle in Hanover assigned to her as a place of residence, where she died after a few years. A monument has been erected to her in Celle. Lenzen published a book on her last hours, containing the celebrated letter written by the queen to her brother George III., in which she asserts her innocence. See also *Die Verschwörung gegen die Königin Karolina Mathilde und die Grafen Struensee und Brandt, nach bisher ungedruckten Originalacten* (Leipsic, 1864).

CARON, or **Carron**, **Franciscus**, a Dutch navigator, perished by shipwreck off Lisbon in 1674. He was of a French Protestant family which had taken refuge in the Low Countries. He engaged when very young as assistant cook on board a vessel departing for Japan. During the voyage he applied his leisure to the study of arithmetic, and after his arrival in Japan learned the native language. This acquisition rendered him especially useful to the Dutch East India company, and he became director of their commerce with Japan, and a member of their council. Colbert was at this time striving to give to France some importance in the commerce of the East Indies, and sought among foreigners men capable of seconding his views. In 1666 Caron accepted letters patent appointing him director general of the French commerce in India, other Dutch and French merchants being joined with him with the same title. Caron arrived at Madagascar in 1667; but, finding the French offices at that island in hopeless confusion, it was decided not to remain there. He departed for Surat, and began operations there with good success. Several of his subsequent plans and operations proved unfortunate, and his imperious and avaricious character excited many enemies against him at court. The minister was constrained to recall him; and, that Caron might not suspect the hostile motive, it was pretended to him that his advice was needed with reference to new enterprises. He embarked for Marseilles, bringing with him a great amount of treasure; but after he had passed the straits

of Gibraltar, he was informed by a vessel which he met of the disposition entertained concerning him at court. He at once turned his ship about and directed his course to Lisbon. He had already anchored in this port, when a heavy sea beat his vessel against a rock, and it went to the bottom with its passengers and cargo, one of his sons alone being saved. He wrote a "Description of Japan," published in 1636.

CARON, René Édouard, a Canadian jurist and statesman, born in the parish of Ste. Anne Côte de Beaupré, Lower Canada, in 1800. He was educated at the seminary of Quebec and the college of St. Pierre, Rivière du Sud, and admitted to the bar in 1826. In 1827 he was elected mayor of Quebec, which office he filled till 1837. In 1841 he was appointed member of the legislative council for Lower Canada, of which body he was speaker from 1843 to 1847, and subsequently from 1848 to 1853. In 1841 he entered into a correspondence with Mr. Draper, then at the head of the government of Canada, with a view of bringing into the cabinet some French Canadians; but the project was not favored by the real chief of the French Canadians, Mr. Lafontaine, and failed. Caron became a member of the Lafontaine-Baldwin administration in 1848, and abandoned political life in 1853, becoming judge of the court of queen's bench, Lower Canada, in which the French civil and the English criminal law are administered. This post he temporarily vacated in 1857, on receiving the appointment of commissioner for codifying the laws of Lower Canada; and when this work was done he returned to his duties as judge. Being superannuated for this office, Mr. Caron entered on the duties of lieutenant governor of Quebec in February, 1873, in the 73d year of his age.

CAROOR, a town of British India, in the presidency of Madras, district of Coimbatore, on the Ambrawutty river, near its junction with the Cavery, 38 m. W. N. W. of Trichinopoly, with which it is connected by railway. It contains about 1,000 houses, has near it a fort and a large temple, and has been in the possession of the British since 1760.

CAROUGE, a town of Switzerland, on the left bank of the river Arve, in the canton and 1 m. S. of Geneva, with which it is united by a bridge; pop. about 5,000. It contains a fine Roman Catholic and a Protestant church and a synagogue. Cotton, leather, and earthenware are manufactured here. Victor Amadeus III. of Sardinia founded the town in 1780, as a rival to Geneva. For a short time it was a resort of political refugees and a centre of the smuggling trade with France; but it declined in importance after the occupation of Geneva by French troops in 1798. It ceased to be under Sardinian rule in 1816, and was assigned to Switzerland. One of the favorite roads from Geneva to the summit of the neighboring Mont Salère is by way of Carouge.

CAROVÉ, Friedrich Wilhelm, a German philosopher and publicist, born at Coblenz, June 20, 1789, died in Heidelberg, March 18, 1852. He was an advocate, held some judicial offices, was made doctor of philosophy by the university of Heidelberg, and officiated for a short time as professor at Breslau. He was one of the founders of the Heidelberg Burschenschaft, and participated in the famous Wartburg festival. He was afterward a member of the provisional German parliament of 1848. His most elaborate works are attacks on the Roman Catholic religion, and include *Ueber die alleinseligmachende Kirche* (2 vols., Frankfurt, 1826); *Was heisst römisch-katholische Kirche?* (2d ed., Altenburg, 1847); *Die Buchdruckerkunst in ihrer weltgeschichtlichen Bedeutung* (Siegen, 1843); and *Ueber das sogenannte germanische und sogenannte christliche Staatsprincip* (1843).

CARP, a malacoptyergian fish, of the family *cyprinidae*, genus *cyprinus*, having the body covered with large scales, a single elongated dorsal fin, fleshy lips, small mouth, with a barbel at the upper part of each corner in the common species, and a smaller one above; teeth in the pharynx, but none in the jaws; branchial rays three; the ventrals behind the

Cyprinus carpio.

pectorals, without any connection with the bones of the scapular arch; the second dorsal ray and the first anal serrated posteriorly; the tail forked; 12 rows of scales between the ventral and dorsal fins. The *C. carpio* (Linn.) is of a golden olive-brown color above, yellowish beneath, and the fins dark brown. It inhabits the fresh-water lakes and streams of central and southern Europe, whence it has been spread by man over the northern parts. It is noticed by Aristotle and Pliny, but was not held in much estimation in ancient times; it grows rapidly, lives to a considerable age, and is exceedingly prolific; it seems to have been introduced into England about 300 years ago. Carps prefer quiet waters, with soft or muddy bottoms, spawning in May or June, according to locality; the food consists of larvae of aquatic insects, worms, and soft plants, though they eat almost any vegetable food in artificial ponds. They are very tenacious of life, and will pass long periods, especially in winter, without food; they afford but little sport to the angler, being very uncertain, and are difficult to take in nets. Their size varies from $\frac{1}{2}$ to $2\frac{1}{2}$ feet, and their weight from

1 to 18 lbs.; they are in season from October to April, and are generally considered excellent for the table. The common carp of Europe has been introduced from France into the Hudson and other waters of New York. The gold fish, or golden carp, is the *C. auratus* (Linn.). The crucian carp (*C. gibelio*, Bloch) is of smaller size, and is considered by some the same as the *C. carassius* (Bloch). In this country the name of carp is erroneously applied to some species of *catostomus* and *luxilus*, belonging to the same family of fishes.

CARPACCIO, Vittore, a Venetian painter, born probably in Istria, died subsequently to 1519. He was a pupil and follower of Giovanni and Gentile Bellini of Venice, and in several of his efforts even surpassed the latter master. His best works belong to the period immediately succeeding 1490, when he painted for the school of Sant' Ursula in Venice nine pictures illustrating scenes in the life of St. Ursula, which are now in the academy of Venice. Another fine work was a "Presentation of Christ in the Temple," painted for the church of San Giobbe. He was an industrious and successful painter till 1515, when, owing to age or debility, his powers began rapidly to decline. He was fertile in invention, a master of perspective, and earnestly impulsive in the conception and rendering of movement. Hence he preferred scenes of life and action, into which he could introduce ordinary objects and incidents, to purely religious subjects. He was an indifferent colorist. Such of his pictures as remain in Venice are more or less injured by damp and efforts to repair them. Fine specimens by him are in the galleries of Milan and Berlin and the Louvre.

CARPÆA, among the ancient Greeks, a kind of mimetic dance peculiar to the Ænians and Magnetes, in Thessaly. It was performed by two armed men, one representing a ploughman and the other a robber, in the following manner: The laborer, laying aside his arms, begins to plough with a yoke of oxen, frequently looking around as if in alarm. When the robber at length appears, the ploughman snatches up his arms, and a fight begins for the oxen. The movements are rhythmical, and accompanied by the flute, and at last the victor takes away the oxen and plough for his reward.

CARPANI, Giuseppe, an Italian dramatist and writer on music, born at Villalbese, near Milan, Jan. 28, 1752, died in Vienna, Jan. 22, 1825. Educated for the law, he devoted himself to literary pursuits, and produced a great number of plays and operas, partly translations and partly original. In 1792 he was editor of the *Gazzetta di Milano*, and wrote violent articles against the French revolution. He was obliged to leave the city after the invasion of the French, and went to Vienna, where he was appointed censor and director of the theatre. In 1809 he accompanied the archduke John in the expedition against Napoleon.

Under the title of *Haydine*, he published a series of curious and interesting letters on the life and works of Haydn the composer. These letters, published in a French translation as an original work, under the name of L. A. C. Bombet, by Beyle (Stendhal), gave rise to a great literary controversy, in which Carpani successfully vindicated his authorship.

CARPATHIAN MOUNTAINS, a mountain system in central Europe, encircling Transleithan Austria on the N. W., N. E., and S., and separating it from Moravia, Austrian Silesia, Galicia, Bukowina, and Roumania. The entire range forms a semicircle about 800 m. long, commencing at New Orsova, on the Turkish frontier, where it is separated from the N. offshoots of the Balkan range only by the Danube, and terminating on the same river in the lofty rock on which the castle of Presburg is situated. Its breadth, including branches on both sides of the Hungarian and Transylvanian frontiers, varies from 100 to 200 m. The highest eminences rise 8,000 or 9,000 ft. above the sea level. The loftiest peaks were formerly thought to be in the Transylvanian section, but recent measurements show that the Gerlsdorf and Lomnitz peaks of the Tatra range, in the Hungarian section, has a greater altitude. The highest parts of the whole Carpathian system consist of granite. Sandstone and limestone are found at a lower level, and basalt, porphyry, jasper, petrosilex, lava, obsidian, and numerous other substances, the result of volcanic and aqueous action, are scattered among the lower ranges. No traces exist of recent volcanic eruption, though there is unquestionable evidence of the extensive agency of fire and water at some time. The Carpathians stand preëminent among the mountains of Europe in respect to mineral wealth. Nearly every metal is produced abundantly from their sides. There are rich mines of silver and gold at Kremnitz and at Schemnitz in Hungary, and a gold mine at Nagy Ag in Transylvania, which is esteemed one of the richest in Europe. Iron, copper, lead, and mercury are also found in large quantities, and rock salt lies in immense deposits throughout both sections of the chain. The Carpathians present four zones of vegetation, rising successively. There is first the woody region, where the oak, beech, and chestnut thrive, which reaches to a height of more than 4,000 ft. above the sea. Then the *pinus abies*, or Scotch fir, appears, and occupies a zone of 1,000 ft. This is succeeded by the moss pine, which diminishes in size as the elevation increases, and at the height of 6,000 ft. appears only as a small shrub and in scattered patches. The open places of this region produce a few blue-bells and other small flowers. From the termination of the moss pine to the summit the mountains have a barren and dreary look, their conical peaks being of naked rock, or covered only with lichens; yet even at these heights a straggling blue-bell or gentian may sometimes be found. None of the Carpathians

are covered with perpetual snow. Small mountain lakes of great depth, called "eyes of the sea," are met with in various parts. Numerous passes intersecting these mountains facilitate communication between the countries lying at their base. The most remarkable and frequented of these are those of Teregova, leading from Orsova to Temesvár; of Vulcan, forming the valley in which the Schyl flows; and of the Red Tower in a gorge formed by the Aluta, at the foot of Mt. Surul. All of these passes were formerly strongly fortified to prevent the entrance of the Turks into Transylvania, but several of them have nevertheless at various times been forced. (See HUNGARY, and TRANSYLVANIA.)

CARPATHUS. See SCARPANTO.

CARPEAUX, Jean Baptiste, a French sculptor, born in Valenciennes, May 14, 1827. He studied in Paris, obtained the prize of Rome in 1854, produced his first statue, a fisher boy, in 1859, and acquired reputation in 1863 by his group of Ugolino and his children, which was purchased by the government and attracted attention by a bold departure from classical models. Conspicuous among his subsequent productions are a Neapolitan fisherman, in Baron Rothschild's gallery; a girl with a shell, in possession of the duchess de Mouchy; and many busts. In 1865 he executed for the Flora pavilion of the Louvre statuary exhibiting imperial France as enlightening the world and protecting agriculture and science. His subsequent work representing dancing on the façade of the new opera house has been highly praised for its singular picturesqueness, and much censured for violating the conventional rules of art; and an unavailing attempt to damage it by corrosive ink was made soon after its appearance, in the night of Aug. 27, 1869.

CARPENTARIA, Gulf of, the largest bay of Australia, deeply indenting the northern coast, between lat. 10° 40' and 17° 30' S., and lon. 137° and 142° E. No settlement has yet been made on its coast. The name is derived from Peter Carpenter, who from 1623 to 1627 was governor general of the Dutch possessions in the East Indies.

CARPENTER, Lant, LL. D., an English clergyman, born at Kidderminster, Sept. 2, 1780, died April 5, 1840. He was of a nonconformist family, and at an early age was adopted and educated by Mr. Pearsall, a relative of his mother. Designed for the ministry, he was sent in 1797 to the Northampton academy. That school being temporarily discontinued, he was placed at Glasgow college. Leaving college in 1801 without his degree, he spent some time in teaching, and as librarian of the Athenæum, Liverpool. While at the academy he became imbued with liberal religious views, and at Liverpool he allied himself with the Unitarian denomination, receiving several invitations to the pastoral charge of Unitarian congregations, and a call to a professorship in their college at York. In 1805 he finally accepted a call to

succeed Dr. Thomas Kenrick at Exeter, where he continued for 12 years. From Exeter he removed to the pastoral charge of the Unitarian congregation at Bristol (1817), where he continued with a short interval until his death, which occurred by falling overboard between Naples and Leghorn, while on a tour for his health. His piety was of an eminently practical turn. The instruction of children was an object of constant interest, and he established Sunday schools among the children of Exeter and Bristol. Among his more important works are "An Introduction to the Geography of the New Testament," "Unitarianism the Doctrine of the Gospel," "Examination of the Charges against Unitarianism," "Harmony of the Gospels," and a volume of sermons.

CARPENTER, William Benjamin, an English physiologist, son of the preceding, born in Exeter in 1813. He was originally intended for an engineer, but graduated as doctor of medicine at Edinburgh in 1839. One of his earliest papers, published in the "Edinburgh Medical and Surgical Journal," was on the "Voluntary and Instinctive Actions of Living Beings;" and in this and other early papers he laid the foundations of those views which he afterward developed more fully in his "Principles of General and Comparative Physiology, intended as an Introduction to the Study of Human Physiology, and as a Guide to the Philosophical Pursuit of Natural History" (8vo, London, 1839). After receiving his diploma in Edinburgh, he settled in Bristol, and became lecturer on medical jurisprudence in the medical school of that city. In 1843 and subsequent years he produced the "Popular Cyclopædia of Science," embracing the subjects of mechanics, vegetable physiology and botany, animal physiology, and zoology. These were professedly compilations, but they contain original views on many points of interest. In 1846 he published "Principles of Human Physiology," which reached a 7th edition in 1869. In 1854 a 4th edition of his "Principles of Comparative Physiology" was published, followed by the "Principles of General Physiology." These two works, with that "On Human Physiology," form three independent volumes, comprising the whole range of biological science. The articles on the "Varieties of Mankind," the "Microscope," "Smell," "Taste," "Touch," "Sleep," "Life," "Nutrition," and "Secretion," published in the "Cyclopædia of Anatomy and Physiology," are also from his pen. Having written much as a popular disseminator, as well as an original investigator of science, he has been accused of being a plagiarist and mere compiler. In answer to this charge, he claims, in the preface to the 3d edition of his "General and Comparative Physiology," the following facts and doctrines as his own: 1. The mutual connection of vital forces, and their relation to the physical. This doctrine is fully developed in a paper on the "Mutual Rela-

tions of the Vital and Physical Forces," in the "Philosophical Transactions" for 1850. 2. The general doctrine that the truly vital operations of the animal as well as the vegetable organism are performed by the agency of untransformed cells, which was first developed in an "Essay on the Origin and Functions of Cells," published in the "British and Foreign Medical Review" for 1843. 3. The organic structure of the shells of mollusca, echinodermata, and crustacea, of which a full account is contained in the "Reports of the British Association" for 1844 and 1847. 4. The application of Von Baer's law of development from the general to the special to the interpretation of the succession of organic forms presented in geological time. 5. The relation between the two methods of reproduction, that by gemmation and that by sexual union, with the application of this doctrine to the phenomena of the so-called "alternations of generations;" first developed in the "British and Foreign Medico-Chirurgical Review" for 1848 and 1849. 6. The relation between the different methods of sexual reproduction in plants; first developed in the same periodical for 1849. 7. The application of the doctrine of reflex action to the nervous system of invertebrata, especially articulated animals; first developed in the author's prize thesis, published in 1839. 8. The functional relations of the sensory ganglia to the spinal cord on the one hand, and to the cerebral hemispheres on the other.—In 1856 Dr. Carpenter published a work "On the Microscope, its Revelations and its Uses," in which he displayed the same industry, accuracy, and impartiality as in his other writings. He has also published several interesting papers on the fossil forms of the family of *foraminifera*, and "An Introduction to the Study of the Foraminifera." He has been professor of medical jurisprudence in University college, London; lecturer on general anatomy and physiology at the London hospital and school of medicine; and registrar to the university of London. In 1849 he gained the prize of 100 guineas offered for the best essay on the subject of "Alcoholic Liquors." This essay was published in 1850, and acquired great popularity among the advocates of total abstinence. He was editor for many years of the "British and Foreign Medico-Chirurgical Review," and while thus occupied with writing he was also much engaged in lecturing. In 1872 he was president of the British association for the advancement of science.—Dr. Carpenter's more recent labors have been directed to the subject of submarine animal life, and the temperature and constitution of the oceanic waters at various depths, as indicated by the result of deep-sea dredgings. In 1868 he made an expedition, in a government vessel fitted for this purpose, to the waters between the north of Scotland and the Faroe islands; in 1869 an expedition to the Atlantic ocean south and west of Ireland, and a second to the neighborhood of the Faroe

islands; and he has since given a report of similar investigations in the waters of the Atlantic between Great Britain and Portugal, and in those of the Mediterranean. The results of these observations show that submarine animal life does not, as was formerly supposed, diminish rapidly at the depth of 100 fathoms, and nearly disappear at 300, but that it is abundant at much greater depths; living mollusks, crustaceans, and protozoa having been brought up by dredging from depths varying from 450 to 2,435 fathoms. He also found that in the North Atlantic, between the Hebrides and the Faroe islands, at from 400 to 550 fathoms' depth, there are warm and cold areas, the former having a minimum temperature of from 46° to 49° F., the latter from 32° to 33½°; while the surface temperature is nearly the same in both, namely, from 50° to 52°. The deep waters of the Mediterranean, on the other hand, were found to have nearly a uniform temperature throughout, namely, between 54° and 56½° F. The saltness and density of the waters of the Mediterranean, also, were found to be greatest near the bottom, while in the Atlantic they are greatest at or near the surface.

CARPENTRAS (anc. *Carpentoracte*), a city of France, in the department of Vaucluse, on the left bank of the Auzon, at the foot of Mont Ventoux, 15 m. N. E. of Avignon; pop. in 1866, 10,848. It is surrounded by high walls and beautiful walks, has a large Gothic cathedral with a spire of the age of Charlemagne, a departmental college, and a public library with 28,000 volumes and many valuable manuscripts. Under the Romans Carpentoracte was an important town of Gallia Narbonensis. Under Pope Clement V. in 1313 it was the seat of the holy see, to which with Avignon it belonged till 1791. From the 3d century till 1801 it was the seat of a bishopric.

CARPET, a sort of thick cloth, used principally for covering the floors of apartments. In its place, at a very early period, straw, rushes, and other coarse materials were used. Improving upon this, the rushes were plaited into matting, which, though homely enough in appearance, served to promote warmth and comfort. In England, where wool was obtained in abundance, a kind of coarse woollen cloth was often seen upon the floors of the gentry. As late as the time of Queen Mary rushes were strewn on the floor of her presence chamber, though carpets had long before been introduced from the East. In Egypt their manufacture is traced back to a very remote period; and in Persia and other Asiatic countries the art, practised by the hand, had attained a high degree of excellence long before it was known in Europe. Purple carpets of great beauty were used at the banquets of the ancient Greeks, spread beneath their couches. The Babylonians, still earlier, ornamented their fabrics with figures of men and strange devices of fabulous creatures. These were

imported by the Greeks and Romans; and from what we know of the fabric, it appears to have been rather of the nature of tapestry than of what we now call carpets—made by introducing tufts of woollen yarn into a warp stretched in a frame, which are held down by a woof passed over each tuft. Such is the method of carpet weaving now practised by the Asiatics, the stitches being made one by one by the slow and tedious operation of the fingers. Young girls acquire great skill in this work, and their hands and eyes are soon trained to do it with ease and rapidity; but by one of the modern machines 1,000 stitches are sooner made than one by the hand process. In Persia whole families, and even tribes, are employed in carpet weaving. These carpets are, however, of so small a size that they are little used. They are purchased by travelling merchants, who dispose of them to Europeans in Smyrna and Constantinople. These carpets are also woven by families, and no large manufactory for them exists. They are in one piece; the patterns are peculiar, and no two are ever made exactly alike. Their chief beauty consists in the harmonious blending of the colors, and in the softness of their texture, rendering them agreeable both to the eye and to the foot. In the process of manufacturing the weaver sits in front of the loom, and fastens to each thread of the warp a bunch of colored yarn, varying the color according to the pattern. The row being completed, he passes a linen woof through the web, and drives it well up, so that all the bunches may be securely fastened. In this way narrow breadths of carpet are made, which are afterward laid side by side and united, so as to form one large piece. The tufts are then pared of equal length, and being beaten down, the whole presents a smooth, even surface. Rugs are made in the same manner. In British India the manufacture of carpets is carried on to a great extent. In Benares and Moorshedabad costly carpets of velvet with gold embroidery are made. Silk-embroidered carpets are manufactured in various places; the woollen ones principally at Masulipatam.—For many years Europe received all her supplies of carpets from the East. The manufacture is said to have been introduced into Europe by the French in the reign of Henry IV. The manufactory now belonging to the French government, and still producing excellent fabrics, was established at Beauvais in 1664 by Colbert, minister of Louis XIV. Another large factory was at Chaillot, a league from Paris, where the carpets were worked in the manner of the modern Wilton carpet. The first successful operations in England were at Mortlake, in Surrey, to which enterprise James I. contributed £2,676. In the middle of the 18th century the business was much extended in different localities, and in 1757 a premium was awarded by the society of arts to Mr. Moore for the best imitation Turkey carpets. This kind of carpet was afterward largely

produced at Axminster, in Devonshire, made even more expensive than the real Turkey by the substitution of worsted for woollen yarn; but the manufacture ceased here, and in Yorkshire also, many years ago. The other varieties of carpets in use, as the Kidderminster or two-ply, called in this country the ingrain, the three-ply, the Venetian, Brussels, and Wilton, are all made by machinery. The ingrain, made with two sets of worsted warp and two of woollen weft, consists of two distinct webs incorporated into each other at one operation, the warp threads passing from one to the other to bring the required colors to the surface. Each web, however, is a cloth of itself, which, if separated by cutting it from the other, would present a coarse surface like baize. Two colors only are used to best advantage in this kind of carpet, the introduction of more tending to give a striped appearance. The three-ply is also ingrained, the threads being interlaced to produce three webs, thus making a fabric of greater thickness and durability, with the advantage of greater variety of color. The pattern, however, does not appear in opposite colors on the two sides in this, as it does in the two-ply. Great difficulty was experienced in applying the power loom to weaving this fabric; in Europe the idea was wholly abandoned; and in 1839 two-ply ingrains were woven at Lowell, Mass., only by the hand loom, at the rate of eight yards a day. At this time Mr. E. B. Bigelow of Boston improved the power loom so that he obtained with it from 10 to 12 yards a day, and afterward by still further improvements so perfected the machinery that the power loom is now wholly used, and with such economy of labor as to have greatly reduced the cost of carpets, and extended their manufacture to meet the increased demand. The inventions of Mr. Bigelow have been so important in this branch of manufacture as to have given it an entirely new character; and though their full description would be too technical and detailed, a general account of those immediately connected with this subject may properly be introduced. The object sought for was a loom which should make carpet fast enough to be economical, one which should make the figures match, and produce a good regular selvege, and a smooth, even face. The hand weaver can at any moment tighten the weft thread, if too loose after the shuttle has been thrown, and so make the selvege regular; if he finds by measurement that, by reason of the irregularity of the weft threads or the ingraining, the figure is being produced too long or too short, he gives more or less force to the lathe in beating up; and if he finds that the surface of the cloth is getting rough, he regulates the tension of the warps. In this way, by observation and the exercise of skill and judgment, he can approximate, and only approximate, to the production of a good and regular fabric. In the first loom Mr. Bigelow

produced, he approximated more nearly than the hand weaver to a perfect match in the figure; and this he effected by taking up the woven cloth by a regular and positive motion which was unerring, the same amount for every throw of the shuttle and beat of the lathe. As the weft threads are not spun regularly, and the weaving in of the warp threads and passing the different colors from the upper to the lower ply or cloth to produce the figures require sometimes more and sometimes less to make a given length, he determined to regulate the delivery of the warps as required by their tension, thereby throwing the irregularities into the thickness, where they cannot be noticed, instead of into the length, where they would destroy the match of the figures. He accomplished this by suspending a roller on the woven cloth, between the lathe and the rollers that take up this cloth, so that when the cloth was being woven too short, which indicates a deficient supply of warps, the roller would be elevated, and by its connection increase the delivery motion to give out more warps, and *vice versa*. Still this served only to prevent the further extension of a fault already incurred. The roller, to perfectly accomplish its purpose, should have been applied to the unwoven warps, which seemed then impracticable; for when the lathe beats up the weft, these must be rigid to resist the beat, and no way was apparent to make the roller sensitive to detect and indicate the amount taken up. The warps, moreover, are necessarily all rolled up on the warp beam with equal tension, and so can only be given out equally. The improvement was afterward perfected by Mr. Bigelow in the following manner: Each warp thread in the usual way passes through a loop called a mail, attached to a card suspended from the jacquard, and each card has suspended to it a weight, all the weights being equal. The two trap boards of the jacquard move simultaneously, one up and the other down, and in these movements they catch or trap such of the cards (determined by the combination of cards) as are required to bring up the proper warp threads at each operation to produce the figure, leaving down such of them as are not required at that particular operation; and when the two trap boards are on a level, and all the warp threads connected with them are in a horizontal line, and those not connected with them hang down with the suspended weights, the lathe beats up the weft thread, which lies between the warps that are in a horizontal line, at the same time exerting a force on the weft threads previously thrown, and beating them up more closely. Now, as the warp threads are all connected at one end with woven cloth, and at the other with the beam, it follows that those which are hanging down in a bent line will receive a greater proportion of the force of the beat of the lathe than the others; and as all the warp threads in succession take this position, and all have an equal weight, it follows that each suc-

cessively receives the same pull at the time the lathe beats up; thus the tendency to irregularity of surface from the varying lengths of warp threads taken up in ingraining is counteracted. The selvage was made smooth and even by a contrivance which regularly gave a pull to the weft thread after the shuttle was thrown. Mr. Bigelow at last, by these improvements and others which he introduced, brought the loom to average from 25 to 27 yards a day of two-ply, and from 17 to 18 yards of three-ply carpet. His improved method of producing figures that will match was afterward introduced, and patented in 1845. The same machinery was found to be applicable to the manufacture of Brussels and tapestry carpets, the weaving of which otherwise than by hand was before generally considered a mechanical impossibility. With the hand loom they were made at the rate of three or four yards per day; but with the improved loom the production was increased to 18 or 20 yards per day. The carpets, too, were made more exact in their figures, so that these perfectly matched, and their surface was smooth and regular. They surpassed, indeed, in their quality the best carpets of the kind manufactured in any other part of the world. The looms of Mr. Bigelow were introduced into factories built at Lowell, Mass., and Thompsonville and Tariffville, Conn., for their use, and others were established at Clinton, in Worcester co., Mass., where carpets are now made to the annual value of about \$1,000,000.—Brussels carpet is so named from Brussels in Belgium, whence the style was introduced into England in the last century. It is made upon a ground of linen weft, which is concealed by the worsted threads that are interlaced with and cover it. The threads are commonly of five different colors. In the weaving these run the length of the web, and are so managed that all those required by the pattern are brought up together across the line of the carpet; before they are let down, a wooden instrument called a sword is passed through to hold up the threads; this is replaced by a round wire, which, being at last removed, leaves a row of loops across the carpet. In a yard length the number of successive lifts of the sets of colors required is sometimes as many as 320, each of which forms a row of loops. Four colors must always lie beneath the fifth, which appears on the surface, and thus the carpet, with its linen weft too, is thick and heavy. The Wilton carpet, the *moquette* of the French, differs from the Brussels in the loops being cut before the wire is removed, a groove in the flat upper surface of the wire admitting of their being cut by passing a knife along the surface. The soft ends give the carpet a rich velvety appearance. In the imperial Brussels carpet the figure is raised above the ground of the pattern, and the loops of this are cut, but not those of the ground. Various methods have been devised of simplifying the processes of making Brussels carpet. Richard Whytock of Edin-

burgh introduced an ingenious plan of using threads dyed of the colors in the succession they would be required; this was done before they were made into the warp, and by a systematic arrangement, and thus a considerable proportion of the threads was dispensed with. His looms produce what are known as "patent tapestry and velvet pile" carpets. Another device is to weave the carpet in plain colors, and then print it with rollers or with blocks, after the method of calico printing. On account of the thickness of the fabric, difficulty is experienced in introducing sufficient color without going over the work many times. In doing this, the difficulty is of course increased of retaining each color within its own exact limits. Rollers were first used; but a cheap kind of carpet is now produced at Manchester, England, by block printing. Felt carpets are also printed in colors in this country.—Venetian carpets (which, by the way, were never a production of Venice) are made with a heavy body of worsted warp, which completely hides the woof; this should be an alternate shoot of worsted and linen yarn. The fabric admits of little variety of design. It is made in narrow widths for stairways and passages.—The patent wool mosaic carpet is a novel manufacture carried on by Messrs. John Crossley and Sons, of Halifax, England. A strong, plain cloth is used as a ground; upon this a pile of warp threads, first arranged over and under parallel strips of metal, which are cut out, leaving the ends like those of a Wilton carpet, is placed and cemented with caoutchouc. If the threads were of different colors, stripes are produced, or the yarns may have been colored by Whytock's plan, or colored patterns may be obtained by another process in use. This method is principally applied to the production of small articles.—Great Britain is the principal seat of the carpet manufacture of the world. The following table shows the exports of carpets from Great Britain to other countries in 1871; and from this it will be observed that, notwithstanding there are several million yards of carpets made yearly in the United States—one company, at Lowell, Mass., producing 37,000 yards per week—more than 65 per cent. of the exports of British carpets come to this country:

CARPI. I. A town of Italy, in the province and 9 m. N. N. W. of Modena, on the canal of Secchia; pop. about 5,000. It has a citadel, walls, a cathedral, several churches, and a seminary, and is the seat of a bishop. Silk culture and the manufacture of straw hats are the chief branches of industry. It was the principal town of the principality of Pico till 1530, when it was acquired by Modena. **II.** A fortified town of Italy, in the province and 28 m. S. E. of Verona, on the Adige; pop. about 1,200. In 1701, during the war of the Spanish succession, the French were defeated here by Prince Eugene.

CARPI, Ugo da, an Italian painter and engraver, born in Rome about 1486, died in the second quarter of the 16th century. He is chiefly known as the inventor of a species of engraving on wood, which consists in the use of separate blocks for the dark shadows, the light shadows, and the demi-tints. His prints are slightly executed, but spirited. They are mostly from the works of Raphael and Parmigiano. Bartsch in his "Peintre-Graveur" describes 15 prints attributed to Carpi.

CARPINI, Giovanni di Piano, an Italian Franciscan monk and traveller, born about 1220. In 1246 he was sent with a company of several other Franciscans on a mission to the great khan of Tartary, to convert him to Christianity if possible, or at least to induce him rather to employ his arms against the Saracens and Turks than against the Christians. Carpini travelled through Russia and along the shores of the Black sea, and finally reached the court of the Tartar monarch, in the region N. E. of the Caspian. He remained here a month or more, without apparently accomplishing much, and then set out on his return, which he effected safely, though not without much suffering. He wrote an account of his journey in Latin, an abstract of which was published in the "Voyages and Discoveries" of Hakluyt. He devoted the remainder of his life to preaching the gospel in Hungary, Bohemia, Norway, and Denmark, and died at an advanced age.

CARPINO, a town of S. Italy, in the province of Capitanata, situated on Mt. Gargano, near Lake Varano, 22 m. N. E. of St. Severo; pop. about 6,000, including the whole commune. It contains several churches, and is situated in a region celebrated for picturesque scenery.

CARPOCRATES, or *Carpocras*, an Alexandrian theologian, of the Gnostic school, flourished under the reign of Hadrian in the 2d century. The fundamental Gnostic idea of a Supreme Being entirely disconnected with the affairs of the universe was the starting point of Carpocrates. The demiurge, and the other finite spirits ruling over the material universe, were striving to keep humanity from unity with the supreme monad, to which it was constantly tending on account of its having been an original emanation from him. The preëxistent state of the human soul was that period when it had been in perfect unity with the supreme monad.

The demiurge and ruling spirits have drawn it away from this union. One of their methods of accomplishing it is by laws or religious duties and observances, such as self-denial and control of appetites and passions, and general humiliation and penances. This Gnostic antinomianism developed itself into a practical life of freedom from moral restraint, which Carpocrates and his son Epiphanes took all pains to justify. The gratification of the appetites and passions became a duty, and salvation by Jesus was only attainable on the condition of perfect abandonment to an antinomian life. Jesus was simply a man of superior soul, who had the power to discern the real difficulty, and strength to achieve his own practical redemption and point the way for others. Carpocrates and his followers rejected the gospels of Matthew and Luke, and the entire Old Testament, as the contrivance of the demiurge to keep men in subjection. They also denied the resurrection of the body.

CARPZOV, a family of learned Germans, said to be descended from a Spanish family named Carpezano, who were driven from their country by religious persecution at the beginning of the 16th century. The founder of the German family was SIMON CARPZOV, burgomaster of Brandenburg about 1550. His son JOACHIM reached a high rank in the Danish army, and died in 1628; and another son, BENEDICT (1565-1624), was professor of jurisprudence at Wittenberg, chancellor of the dowager electress Sophie, and again professor. Benedict left five sons, one of whom, also named BENEDICT (1595-1666), acquired eminence as a jurist in Leipsic and Dresden, and his *Practica nova Rerum Criminalium* (Wittenberg, 1635; new ed. by Böhmer, 5 vols., Frankfort-on-the-Main, 1758) and other works exerted great influence on the judiciary in Saxony and other countries. His four brothers were likewise men of great erudition and piety, especially JOHANN BENEDICT (1607-'57), who was professor of theology and preacher at Leipsic, and the author of *Systema Theologiae* (2 vols., Leipsic, 1653) and other works. The latter had a son also named JOHANN BENEDICT (1639-'99), a clergyman, who published *De Pontificum Hebraeorum Vestitu* and other critical works. Prominent among the brothers of the preceding were FRIEDRICH BENEDICT (1649-'99), collaborator in Mencken's *Acta Eruditorum*, and SAMUEL BENEDICT (1647-1707), professor of poetry and chief chaplain of the court of Saxony. One of the latter's sons, JOHANN GOTTLÖB (1679-1767), was in the front rank of the theologians of his day. He was professor of oriental languages at Leipsic (1719-'30), and superintendent at Lübeck (1730-'67); and his works include *Introductio in Libros Canonicos Bibliorum Veteris Testamenti Omnes* (Leipsic, 1721), and *Critica Sacra Veteris Testamenti* (1728). Among the later members of the family was JOHANN BENEDICT (1720-1803), who was successively professor of philosophy at Leipsic and of poetry and Greek philology at

Helmstedt, and ended his life as an abbot after having taught theology. He occupied himself with philological labors, especially with grammatical commentaries on the New Testament.

CARR, Dabney, a member of the house of burgesses of Virginia, born in 1744, died at Charlottesville, May 16, 1773. He moved and eloquently supported a resolution to appoint a committee of grievances and correspondence, in consequence of British encroachments, which was adopted, March 3, 1773. He married a sister of Jefferson, by whom he is described as a man of eloquence, judgment, and inflexible purpose, mingled with amiability.

CARR, Sir Robert, British commissioner in New England, died at Bristol, June 1, 1667. He was appointed to that office by Charles II. in 1664, in conjunction with Nicolls, Cartwright, and Maverick. In 1664 Nicolls and Carr captured New Amsterdam from the Dutch, and called it New York, in honor of the king's brother, the duke of York, afterward James II. Carr forced the Swedes and Dutch on the Delaware into a capitulation. He returned to Boston in 1665, and in conjunction with his coadjutors assumed the government.

CARRACCI. I. Ludovico, the founder of the Bolognese school of painting, born in Bologna in 1555, died there in 1619. His first master, Prospero Fontana, a Bolognese painter, so little appreciated his capacity that he advised him to adopt some other profession. His slowness of execution was so remarkable that his fellow pupils called him in ridicule the ox. From Bologna he went to Venice, and studied with Tintoretto. Subsequently he visited Florence and Parma, where he gave much attention to the works of Andrea del Sarto, Correggio, and Parmigiano. The object of these varied studies was presently developed in the establishment of his school of painting, known as the eclectic school of Bologna. In this project he secured the assistance of his cousins Agostino and Annibale, who joined him in Bologna about 1585. In a few years their school was overflowing with pupils, and all the others in Bologna closed. As the head of the academy, Ludovico resided chiefly at Bologna; and his merit is more that of a teacher than of a productive artist. He has left many works at Bologna, including his fresco paintings in the palazzi Magnani and Zampieri; his series of scenes from the history of St. Benedict and St. Cecilia, in the convent of St. Michael at Bosco; an "Assumption of the Blessed Virgin," one of his best works; and the "Birth of St. John the Baptist." He also painted many "Ecce Homos" and "Pietàs." **II. Agostino**, cousin of the preceding, born at Bologna in 1558, died in 1601. He was the son of a tailor, was instructed in the goldsmith's art, and afterward became an engraver. At the invitation of Ludovico he embarked in his project for founding a new school of art in Bologna, but first went through a course of studies at Bologna, Rome, Parma, and Venice. To Agostino were assigned the

most important and laborious duties. He prepared treatises on architecture and perspective, lectured on anatomy, and suggested subjects for composition, drawn from history or fiction. He also proposed and awarded prizes for designs, celebrating the victor's triumph with music and song. His early predilection for engraving never forsook him, and, although his designs were numerous, he finished fewer paintings than either of the other Carracci. Among the best specimens of his paintings are "St. Jerome receiving the Sacrament before Death," at Bologna, and the "Infant Hercules strangling the Serpents," in the Louvre. **III. Annibale**, brother of the preceding, born in Bologna in 1560, died in Rome in 1609. He was at first a tailor, but was instructed in painting by Ludovico, and afterward sent to Parma and Venice, where he devoted years to the works of Correggio and the great Venetian colorists. His style was founded on the eclectic principle adopted by Ludovico. He was an industrious painter, and the works of this period of his life are numerous. His contributions to the palazzi Magnani and Zampieri in Bologna, in which he assisted Ludovico, were highly esteemed. In 1600, by the invitation of Cardinal Farnese, he visited Rome, where, under the influence of Raphael and Michel Angelo, his style developed itself in a new form. He was employed to paint for various churches in Rome, but his chief work is the series of frescoes of mythological designs in the Farnese palace, and particularly in the gallery, which occupied him eight years. At the commencement of this work he was assisted by Agostino; but the intercourse between the brothers, when they were not under the influence of Ludovico, was always liable to be interrupted by jealousies and disputes, and Annibale was soon left to labor alone. When the work was at length completed, the artist received only 500 crowns. Irritated by this parsimony, and enfeebled in health by long confinement, he repaired to Naples. The persecutions of the Neapolitan artists obliged him to return to Rome, where he died soon afterward. Besides the contributions to the Farnese palace, which have been frequently engraved, "St. Roch distributing Alms," in the Dresden Gallery, a "Dead Christ supported by the Madonna," the "Resurrection," at Bologna, and the "Three Marys" in the collection at Castle Howard, are among his most celebrated works. He was one of the first to practise landscape painting as a separate department of art. **IV. Francesco**, brother of the preceding, born at Bologna in 1595, died in Rome in 1622. He studied painting with Ludovico, and attempted to establish a rival school in Bologna, over the door of which he caused to be inscribed "This is the true school of the Carracci." The project failed.

CARRANZA, Bartolomé de, a Spanish prelate, born at Miranda in 1503, died in Rome, May 2, 1576. He early gained distinction as professor of theology at Valladolid, and attended

in 1546 the council of Trent as envoy of Charles V. He was subsequently tutor of Charles's son, afterward Philip II., whom he accompanied to Winchester in 1554, on his marriage to Mary of England, whose confessor he became, zealously coöperating with her in the interests of the church of Rome. Shortly after his accession to the throne Philip II. appointed him primate of Spain. In 1558 he was arrested by order of the inquisition on account of his *Comentarios sobre el catechismo cristiano*, though the catechism was approved by the council of Trent. His alleged heterodox influence upon Charles V. at his deathbed also gave offence. In 1567 his condition as a prisoner was ameliorated by his being removed to the castle of San Angelo in Rome; but he was not released till 1576, and died a few weeks afterward. His principal work, *Summa Conciliorum* (Venice, 1546), passed through many editions.

CARRARA, a city of Italy, in the province of Massa-Carrara, on the Avenza, 59 m. S. W. of Modena; pop. about 7,000. Its principal edifices are the college, the palace of the former dukes of Modena, the collegiate church, and the church of Madonna delle Grazie. An academy of sculpture was founded here by Napoleon, and many artists from abroad reside here to superintend the transport of marble, or to execute works of art. The inhabitants are chiefly engaged in the preparation of marble, which is obtained in the vicinity.

CARRARA MARBLE, a beautiful white marble, of fine granular texture, deriving its name from the city of Carrara. The Parian differs from it in being composed of the most delicate little plates or scales, confusedly united together. The magnificent chain of mountains in which the quarries of Carrara marble are situated forms a portion of the Apennines, and is included in the province of Massa-Carrara. These mountains are distant about 4 m. from the seashore, and present a very imposing appearance, towering to the skies, and broken into rugged and inaccessible peaks. The quarries, among which are those that furnished the material for the Pantheon at Rome, are about half way up the mountain; and although they have been worked for many centuries, and the annual export has long amounted to about 40,000 tons, yet the workmen are still employed upon the surface, so that the supply may be regarded as inexhaustible. The Carrara marbles are of four varieties. That used by sculptors, the white, granularly foliated limestone, is the most valuable. It is more easy to work than the compact limestone, its color is purer, and it is delicately transparent. The other varieties are the veined marble, with colored lines, which render it unfit for statuary; the *ravacioni*, or Sicilian, and the *baidiglio*, of a deep blue color. In working the quarries, large blocks of marble, some of more than 200 cubic feet, are loosened by blasting. When thoroughly detached, they are tumbled down or lowered

to the base of the mountain, whence they are transported to Marino, the port of shipment. This marble range extends over many square leagues. The whole number of quarries is estimated at about 400, of which 40 or 50 are constantly worked, employing about 1,200 men. Those of the statuary marble do not exceed 12 in all, but are the most productive as well as the most valuable. They are the property of a few of the principal families of Carrara. The Carrara marble, which was formerly regarded as a primitive limestone, proved to be an altered limestone of the oölitic period. The causes by which the change of its structure was effected have also served to obliterate all traces of the fossils which are usually found in the rocks of this period. An analysis of the best quality of this marble by Käppel gives :

Carbonate of lime.....	98.7654
Carbonate of magnesia.....	0.9002
Oxides of iron and manganese, and alumina.....	0.0825
Silica, trace of phosphoric acid, and loss.....	0.0961
Quartz sand.....	0.1555

100.0000

CARRAGEEN, or **Irish Moss**, a marine plant (*chondrus crispus*), which grows upon the rocks of the coasts of Europe, particularly of Ireland, and is said to be a native of the United States. It is collected for the preparation of a light and nutritious food for invalids, and is particularly recommended in pulmonary and scrofulous affections, dysentery, diarrhœa, &c. It is prepared by macerating it in cold water, in which it swells without dissolving, and which removes the taste of extraneous matters mixed with it. It is then boiled in water, of which three pints are used to the ounce of moss. Milk instead of water makes a more nutritious preparation. It dissolves and gelatinizes, and the jelly is flavored with lemon juice, and sweetened with sugar. (See *ALGÆ*.)

CARRÉ, Michel, a French dramatist, born in 1819, died at Argenteuil, near Paris, June 29, 1872. He studied at the collège Charlemagne, and published in 1841 a volume of poetry, and in 1843 his first drama, *La jeunesse de Luther*. Subsequently he wrote for the stage together with Jules Barbier and others. Among their joint productions are the librettos of *Les noces de Figaro* (1858), *Le pardon de Ploërmel* (1859), *La reine de Saba* and *Lalla Rouck* (1862), and *Mignon* (1866).

CARBEL, Nicolas Armand, a French journalist, born at Rouen, May 8, 1800, died at St. Mandé, near Paris, July 24, 1836. The son of a merchant, he was educated at St. Cyr, and entered the army as sub-lieutenant. He secretly participated in the Belfort conspiracy in 1821, but eluded suspicion. His political opinions became known on the occasion of the outbreak of the Spanish revolution. A letter he had written to the cortes came into the hands of his colonel, when he resigned his commission, and entered the foreign legion in Spain. When the French army invaded the peninsula, Carrel was made prisoner, and was three times tried

before a court martial, but escaped punishment. He was then engaged for a few months as an amanuensis to the historian Augustin Thierry; subsequently he wrote two essays on the history of Scotland and of modern Greece, and a biographical notice of Paul Louis Courier, the French pamphleteer; he was also editor of the *Revue Américaine*, a short-lived monthly, and an occasional contributor to several leading opposition papers, such as the *Constitutionnel* and the *Globe*. But he did not gain much literary reputation until the appearance of his *Histoire de la contre-révolution en Angleterre*. At the commencement of 1830, with Thiers and Mignet, he founded the *National* as an organ of their political views. Thiers, being the oldest and best known of the three, was the leading editor, while Carrel wrote chiefly for the literary department of the paper. The *National* had much influence in bringing about the revolution of 1830. When it was accomplished, Carrel was sent on a mission into the western departments, where his wise measures and personal influence contributed to maintain tranquillity. During his absence he had been nominated prefect of the department of Cantal; he declined the appointment, and went back to the *National*, of which he now assumed the chief editorship. Under his control, and chiefly by his contributions, the *National* became a most vigorous and eloquent journal, and gave to the republican party a standing which it never had before. The boldness of his course drew on him the anger of the government, but the measures taken against him could not damp his ardor. He was the first to vindicate the memory of Marshal Ney before the court of peers; and his temerity would have been severely punished if he had not been supported by Gen. Excelsmans. His quickness of temper involved him in several duels. His last encounter was with Émile de Girardin, who had challenged him. Girardin was slightly wounded in the thigh, and Carrel received a ball in the abdomen. He was taken to the house of one of his friends at St. Mandé, and died two days after. His collected works have been published (5 vols., Paris, 1858).

CARRENO DE MIRANDA, Juan, a Spanish painter, born in 1614, died in 1685. As a colorist, the Spaniards rank him with Titian and Van-dyke. His principal paintings are a "Magdalen in the Desert," at Madrid; a "Holy Family," at Toledo; and a "Baptism of our Saviour," at Alcalá de Henares.

CARRERA, Rafael, president of Guatemala, born in the city of Guatemala in 1814, of mixed Indian and negro blood, died April 14, 1865. In 1829, when Morazan was president of the federal government, Carrera became a drummer boy. Subsequently he retired to the village of Metaquascuintla, where he married a woman of singularly energetic character, his constant companion throughout his subsequent career. In 1837 he placed himself at the head

of a band of insurgent mountaineers, and in February, 1838, occupied the city of Guatemala with 6,000 Indians, whom he succeeded in restraining from pillage and massacre. Some accommodation among the conflicting parties now followed, and Carrera was sent to Meta, a neighboring district of the interior, in an official capacity. On April 13, 1839, he again occupied the capital, which he subsequently held. Ruling at first as general-in-chief, he was elected, March 21, 1847, to the presidency of Guatemala. Early in 1851, with only 1,500 men, he defeated the combined forces of San Salvador and Honduras. He was reelected Oct. 19, 1851, as president for life. In 1861 he intervened with success in the contest which had arisen between the ecclesiastical authorities in Honduras and President Guardiola. In 1862 he opposed the plan for a confederation of the Central American republics, and the project failed. In 1863 he declared war against San Salvador, took possession of the capital, and expelled President Barrios. In the early part of his career he was regarded as the enemy of order and civilization, but he subsequently proved a mild and conservative ruler. His government was absolute. When first elected to the presidency he was unable to read or write, but he afterward in some measure repaired the deficiencies of his education.

CARBETTO, Francesco Saverio, marquis of, a Neapolitan minister of police, born in Salerno about 1788, died in Naples in December, 1862.

He fought his way to distinction in the army, and, although a member of the carbonari, was in 1823 appointed general inspector of police. In 1828 he marched at the head of 6,000 men to quell an insurrection at the little town of Bosco. After destroying the town he caused a pillory to be erected upon its ruins, and had 20 persons executed, including an old man of 80 years. This drew upon him the wrath of the Neapolitans. King Ferdinand II., however, appointed him minister of police in 1831. For some time he exercised almost absolute power in Naples. In 1837, when the cholera raged in Sicily, and the people were persuaded that it had been intentionally brought into the country by the government, Carretto was despatched to Catania, where the insurgents had organized a provisional government; and although this on his arrival had already been abandoned, he again exercised his authority by ordering the execution of more than 100 per-

sons, even applying the torture to the prisoners. The king was finally compelled to yield to the clamors of the people, and dismiss him. During the night of Jan. 27, 1848, he was arrested and put on board a French steamer, as an exile to France. When the name of the passenger became known at Leghorn, the supply of coals was withheld from the steamer. In Genoa he was not permitted to go on shore. He afterward returned to Naples, but was not restored to office, though he was loaded with favors by the king.

CARRICKFERGUS, a parliamentary borough and seaport of Ireland, county Antrim, situated on Belfast lough, 7 m. N. E. of Belfast; pop. in 1871, 9,452. The town extends about a mile along the shore of Carrickfergus bay, and consists of three parts: the old or walled town in the centre, the Irish quarter on the west, and the Scotch quarter on the east. The inhabitants of the last mentioned quarter are chiefly fisher-

Carrickfergus Castle.

men, descendants of a colony whom religious persecution drove thither in the 17th century. There is an old castle, once very strong, and still fortified. The other public buildings worthy of note are the parish church, an antiquated structure in the form of a cross, and the court house. There are also places of worship for Catholics, Presbyterians, Methodists, and Unitarians. There are flax-spinning mills, a muslin bleach green, and a linen bleach mill and green in the vicinity; and some trade is also carried on in tanning, brewing, and distilling. There is a semi-annual fair. It returns one member to parliament. In ancient times the town was frequently attacked by the Scots. William III. landed here, June 14, 1690. In the roads opposite the town the British sloop of war Drake was captured by Paul Jones, April 24, 1778.

CARRIER, Jean Baptiste, a French revolutionist, born near Aurillac in 1756, executed in

Paris, Dec. 16, 1794. Taking his seat in the national convention in 1792, he supported the establishment of the revolutionary tribunal, voted for the death of Louis XVI., presented a motion for the arrest of Philippe Égalité, duke of Orleans, and participated actively in the popular rising of May 31 against the Girondists. His revolutionary zeal caused him to be sent to Normandy, then to Nantes, where he arrived Oct. 8, 1793. The western departments were troubled by civil war, and he ordered numerous arrests, and sent victims to the scaffold on the slightest suspicion. He soon dispensed with even a show of trial; without any judicial proceedings, prisoners were murdered by wholesale; and as the guillotine did not afford sufficient means of execution, boats provided with valves were procured, which, after receiving on board hundreds of prisoners, were towed to the middle of the Loire, where they were sunk to the bottom with their human cargo. The first of these *noyades de Nantes* comprised 94 priests; several others took place in which women and children were mingled with men. The prisoners were confined in a vast building called the warehouse; every day, at nightfall, numbers of them were summoned on board the fatal boats, and their death was hidden in the darkness of night. He also invented the so-called "republican marriage," in which victims were tied in couples, sometimes a man and woman together, then flung into the river, or forced from the boat by the sword or bayonet. Meanwhile numbers of prisoners were also shot in the vicinity of Nantes. The convention was for a while kept ignorant of these scenes; the killing of prisoners he reported as the "translation of culprits." The citizens of Nantes did not dare to denounce him, as they were under the impression that he acted in accordance with the orders of the convention. At last the assembly became aware of the real state of things, and Carrier was recalled by the committee of public safety. Strongly denounced by public opinion after the fall of Robespierre, he was arraigned before the revolutionary tribunal, Nov. 25, 1794, and sentenced to death.

CARRIERE, Moritz, a German philosopher, born at Griedel, March 5, 1817. He studied at Giessen, Göttingen, and Berlin, and perfected his knowledge of art in Italy. In 1842 he became private teacher in the university, in 1849 professor at Giessen, and in 1853 at Munich, where he lectures chiefly on æsthetics at the university and on art history at the academy. He has written various works on philosophy, religion, poetry, and æsthetics, translated into German the letters of Abélard and Héloïse, composed a poem on the last night of the Girondists, urged the conversion of the cathedral of Cologne into a free church, and developed his liberal ideas in an essay on Cromwell. He has also prepared annotated editions of Goethe's *Faust* and Schiller's *Wilhelm Tell*; and during the

Franco-German war he delivered lectures on *Die sittliche Weltordnung in den Zeichen und Aufgaben unserer Zeit* (Munich, 1870), and on *Deutsche Geisteshelden im Elsass* (1871). He is foremost among German thinkers who seek to reconcile Christianity with science, art, and history, and who are opposed to ultramontanism. His most celebrated work is *Die Kunst im Zusammenhange der Culturentwicklung und die Ideale der Menschheit* (4 vols., Leipsic, 1863-'71).

CARRIER PIGEON, a variety of the common pigeon (*columba livia*). This, the *pigeon privé* of Bélon, the *pigeon domestique* of Brisson, the wild rock pigeon of the British, and the *colommen* of the Welsh, is the stock from which ornithologists generally now agree that the domestic pigeon is derived. The varieties of this bird, produced under the fostering hand of man, the tumblers, croppers, jacobines, runts, spots,

1, 2. Methods of attaching Letters. 3. Liège Carrier.
4. Antwerp Carrier.

turbits, owls, nuns, &c., would fill a volume; the carrier, however, demands especial notice. The carrier pigeon is a bird larger than the common pigeon, measures about 15 inches in length, and weighs about 1½ lb. The neck is long, and the pectoral muscles are very large, indicating a power of vigorous and long-continued flight. An appendage of naked skin hangs across its bill, and continues down on either side of the lower mandible. According to its size and shape the amateurs of carrier pigeons estimate the value of the bird. They consider those pigeons the best that have the appendage rising high on the head, and of considerable width across the bill, and that are also distinguished by a wide circlet around the eyes, destitute of feathers. The instinct which renders this bird so valuable is its very strong love of home, which is in some degree common

to all the domesticated varieties. The mode of training them in Turkey, where the art is supposed to be carried to the greatest perfection, is this: The person who has the charge of rearing and training them takes the young pigeons when they have got their full strength of wing in a covered basket to a distance of about half a mile from their home; they are then set at liberty, and if any of them fail in returning home from this short distance, they are considered stupid, and are rejected as valueless. Those that return home are then taken to greater distances, progressively increased to 1,000 miles, and they will then return with certainty from the furthest parts of the kingdom. In England it is usual to keep these birds in a dark place for about six hours before they are used; they are then sparingly fed, but have as much water given them as they will drink. The paper on which the message is written should be carefully tied round the upper part of the bird's leg, but so as in no wise to impede its flight. It appears from an English ballad, and from a line in Tasso, that in older times the original way of suspending the despatch was from the wing or round the neck; but the above method is that now adopted.—The antiquity of the use of these birds for the purpose of bearing intelligence to distant parts or persons, and the perseverance with which some varieties (that which is named, from its peculiar fitness, the carrier more especially), when well trained, will return from long distances, is well known; but it is not known when or by whom the pigeon was first applied to this purpose. We have the authority of Sir John Mandeville that the Asiatics used them for the same purpose as the Romans. During the crusade of St. Louis they were so employed; Tasso presses them into service in the siege of Jerusalem, making Godfrey defend one when attacked by a falcon; and Ariosto makes the castellan di Damiana spread the news of Orriolo's death by a messenger dove. During the late siege of Paris these birds were employed to convey messages beyond the German lines; very long documents, printed by micro-photography on films indestructible by water, and weighing only a few grains, were thus transmitted with great success. The ordinary rate of the flight of carrier pigeons is not generally held to exceed 30 miles an hour, although instances of a double or even triple rate of velocity are recorded.—The education of carrier pigeons is entirely progressive; the distance flown being gradually and slowly increased from half a mile up to 20 or 30 miles. When the bird is able to accomplish this, he may be trusted to fly any distance overland, within the limits of physical power. The younger the bird is, if it have strength to fly well, the greater is the chance of educating it to be a good bearer of a despatch. If this drilling be not commenced early, birds of the best breed cannot be trusted. When thrown up the bird rises, and when it has reached a good height

will at first fly round and round evidently for the purpose of finding some well known landmark, and then make off, continuing on the wing without stop or stay, unless prevented, till its home is reached. If no such landmark is found, the bird is lost. Thus pigeons, when loosed from a balloon at a great height, have, after flying round and round, returned to the balloon for want of objects to guide them in their homeward flight. The magnetic telegraph has now rendered the service of carrier pigeons, unless in times of siege, of little use.

CARRIGALINE, a parish of Ireland, in the county and 8 m. S. of Cork; pop. about 7,000. It contains fine marble and slate quarries. The village, on Owenboy river, possesses some archaeological interest on account of a ruined castle of the earls of Desmond, and the remains of a religious house and of a Danish fort in the vicinity. The church is a fine building in the perpendicular style. In a neck of the river near by Sir Francis Drake once took shelter, when hard pressed by a Spanish fleet.

CARRO, Jean de, a German physician, born in Geneva, Aug. 8, 1770, died at Carlsbad, March 12, 1857. Taking up his abode in Vienna in 1795, he became celebrated by his efforts in spreading Jenner's system of vaccination as a protection against smallpox in Germany, Hungary, Poland, and Russia. In 1800 he sent a quantity of virus to Lord Elgin at Constantinople, together with a work of his own, translated into Turkish, on vaccination. The attempts of the English to introduce vaccination into India having been unsuccessful, because the virus had deteriorated on the way, Carro procured vaccine matter from cows of Lombardy, and sent it to Dr. Harford at Bagdad. This retained all its strength, and was the means of introducing kinpox inoculation into India. The Hindoos consider it to be derived from a sacred cow, to which they give the name of *amurtum*, or immortality. Carro published *Observations et expériences sur l'inoculation de la vaccine* (Vienna, 1801); *Histoire de la vaccination en Turquie, en Grèce et aux Indes Orientales* (1803); *Carlsbad et ses eaux minérales* (1827); and *Vingt-huit ans d'observation et d'expériences à Carlsbad* (1853). For many years he published annually the *Almanach de Carlsbad*.

CARROLL, the name of 14 counties in the United States. **1.** An E. county of New Hampshire, bordering on Maine; area, about 560 sq. m.; pop. in 1870, 17,332. Lake Winnepiseogee separates it from Belknap county on the S. W., and within its own limits are several smaller lakes and ponds and numerous small streams. The surface is mountainous and broken, Ossipee mountain and Conway peak being the principal summits. The soil is productive, but much labor is required for its cultivation. The Portland and Ogdensburgh railroad runs to North Conway, and the Portsmouth, Great Falls, and Conway railroad is being extended into the county. The chief productions in

1870 were 17,034 bushels of wheat, 106,385 of Indian corn, 59,853 of oats, 327,694 of potatoes, 43,052 tons of hay, 504,194 lbs. of butter, 32,766 of wool, and 177,270 of maple sugar. There were 3,018 horses, 6,801 milch cows, 5,122 working oxen, 8,784 other cattle, 9,059 sheep, and 2,747 swine. There were 2 manufactories of boots and shoes, 5 of carriages and wagons, 4 of furniture, 9 tanneries, 7 currying establishments, 9 saw mills, 2 wool-carding and cloth-dressing establishments, 2 manufactories of cotton and woollen machinery, and 1 of woollen goods. Capital, Ossipee. **II.** A N. county of Maryland, bordering on Pennsylvania, drained by the sources of the Patapsco and Monocacy rivers; area, about 500 sq. m.; pop. in 1870, 28,619, of whom 2,175 were colored. The surface is hilly, and the soil thin, but well cultivated. Copper and iron ores are found. The Baltimore and Ohio railroad skirts the S. part, and the Western Maryland line passes through the county. The chief productions in 1870 were 427,586 bushels of wheat, 35,257 of rye, 716,887 of Indian corn, 425,019 of oats, 118,072 of potatoes, 30,766 tons of hay, 823,759 lbs. of butter, 19,012 of wool, and 225,800 of tobacco. There were 6,564 horses, 8,945 milch cows, 5,531 other cattle, 5,279 sheep, and 19,265 swine. There were 7 manufactories of agricultural implements, 18 of carriages and wagons, 10 of furniture, 3 of iron castings, 17 of saddlery and harness, 11 of tin, copper, and sheet-iron ware, 3 of woollen goods, 5 saw mills, 29 flour mills, 13 tanneries, and 8 currying establishments. Capital, Westminster. **III.** A S. W. county of Virginia, bordering on North Carolina, having the Alleghany mountains on the N. W. and the Blue Nose on the S. E., and drained by affluents of the Kanawha river; area, 440 sq. m.; pop. in 1870, 9,147, of whom 328 were colored. The soil is rough and hilly, but generally adapted to cultivation and grazing. There are mines of copper, iron, and lead. Grayson sulphur springs are much resorted to in summer. The chief productions in 1870 were 13,382 bushels of wheat, 25,080 of rye, 91,772 of Indian corn, 42,658 of oats, 10,837 of potatoes, 2,713 tons of hay, and 74,893 lbs. of butter. There were 1,200 horses, 2,186 milch cows, 3,417 other cattle, 8,632 sheep, and 7,648 swine. Capital, Hillsville. **IV.** A W. county of Georgia, bordering on Alabama; area, 572 sq. m.; pop. in 1870, 11,782, of whom 1,309 were colored. The Chattahoochee and the Tallapoosa are the principal rivers. The surface is mountainous, and the soil, which rests chiefly on a granite foundation, is fertile in many parts of the county. One or two gold mines are worked with profit. The chief productions in 1870 were 40,981 bushels of wheat, 215,338 of Indian corn, 8,997 of oats, 29,640 of sweet potatoes, 113,083 lbs. of butter, and 1,964 bales of cotton. There were 849 horses, 2,354 milch cows, 3,747 other cattle, 5,494 sheep, and 11,892 swine. Capital, Carrollton.

V. A N. W. county of Mississippi drained by branches of the Yallobusha and Yazoo rivers, and bounded S. E. by the Big Black; pop. in 1870, 21,047, of whom 11,550 were colored. The former area was 850 sq. m., but a portion was taken in 1870 to form Grenada county. The surface is level, and the soil alluvial and remarkably fertile. The Mississippi Central railroad passes through the E. part. The chief productions in 1870 were 6,821 bushels of wheat, 433,245 of Indian corn, 29,794 of sweet potatoes, and 14,135 bales of cotton. There were 1,809 horses, 2,552 mules and asses, 4,346 milch cows, 8,566 other cattle, 3,955 sheep, and 20,388 swine. There were 5 saw mills and 1 manufactory of cotton goods. Capital, Carrollton. **VI.** A N. E. parish of Louisiana, bordering on Arkansas, between the Mississippi river and Bœuf bayou; area, 1,050 sq. m.; pop. in 1870, 10,110, of whom 7,718 were colored. The surface is generally level. The chief productions in 1870 were 142,525 bushels of Indian corn, 12,765 of sweet potatoes, and 20,384 bales of cotton. There were 683 horses, 1,424 mules and asses, 1,504 milch cows, 3,164 other cattle, and 5,051 swine. Capital, Providence. **VII.** A N. W. county of Arkansas, bordering on Missouri, and intersected by Long creek and King's and White rivers; pop. in 1870, 5,780, of whom 37 were colored. The former area was 1,038 sq. m., but a portion has recently been taken to form Boone county, while a part of Madison county has been added to this. The surface is diversified, and the soil generally fertile. Several quarries yield excellent variegated yellow marble. The chief productions in 1870 were 20,488 bushels of wheat, 172,696 of Indian corn, 45,447 lbs. of butter, 15,445 of tobacco, and 6,226 gallons of molasses. There were 1,957 horses, 1,135 milch cows, 2,517 other cattle, 4,590 sheep, and 14,174 swine. There were 5 saw mills in the county. Capital, Carrollton. **VIII.** A W. county of Tennessee, drained by affluents of the Big Sandy and Obion rivers; area, 625 sq. m.; pop. in 1870, 19,447, of whom 4,799 were colored. The surface is flat, and the soil fertile. There are extensive forests of oak, hickory, maple, and black walnut. The Louisville and Memphis and the Nashville and Northwestern railroads traverse the county. The chief productions in 1870 were 93,872 bushels of wheat, 777,922 of Indian corn, 272,083 lbs. of butter, and 5,023 bales of cotton. There were 3,517 horses, 2,265 mules and asses, 4,076 milch cows, 5,362 other cattle, 10,822 sheep, and 35,018 swine. There were 5 flour and 4 saw mills, and 3 wool-carding and cloth-dressing establishments. Capital, Huntingdon. **IX.** A N. county of Kentucky, bordering on Indiana, bounded N. by the Ohio, and intersected by the Kentucky river; area, about 200 sq. m.; pop. in 1870, 6,189, of whom 540 were colored. In the N. part the surface is occupied by steep hills; elsewhere the land is undulating and fertile. Most of the soil is calcareous, and

limestone is abundant. The Louisville, Cincinnati, and Lexington railroad passes through the S. part. The chief productions in 1870 were 38,236 bushels of wheat, 263,629 of Indian corn, 26,965 of potatoes, 12,640 lbs. of wool, and 669,875 of tobacco. There were 2,058 horses, 1,282 milch cows, 2,480 other cattle, 3,495 sheep, and 6,489 swine. There were 4 flour and 3 saw mills, and 1 manufactory of woollen goods. Capital Carrollton. **X.** An E. county of Ohio; area, 360 sq. m.; pop. in 1870, 14,491. It is somewhat hilly, but well watered and fertile. Hard coal and iron ore are found. The Tuscarawas branch of the Cleveland and Pittsburgh railroad, and the Carrollton and Oneida railroad traverse the county. The chief productions in 1870 were 211,008 bushels of wheat, 23,699 of rye, 417,864 of Indian corn, 520,663 of oats, 75,819 of potatoes, 27,133 tons of hay, 600,785 lbs. of butter, and 538,589 of wool. There were 5,628 horses, 6,314 milch cows, 6,720 other cattle, 131,069 sheep, and 10,230 swine. There were 3 flour, 3 saw, and 3 planing mills, 7 tanneries, and 5 currying establishments. Capital, Carrollton. **XI.** A N. W. central county of Indiana, drained by the Wabash and Tippecanoe rivers; area, 378 sq. m.; pop. in 1870, 16,152. The surface is diversified and well timbered, and the soil productive. It is traversed by the Wabash and Erie canal, and by the Toledo, Wabash, and Western railroad. The chief productions in 1870 were 521,689 bushels of wheat, 401,635 of Indian corn, 65,738 of oats, 36,834 of potatoes, 7,475 tons of hay, 236,988 lbs. of butter, and 69,452 of wool. There were 5,175 horses, 4,268 milch cows, 6,640 other cattle, 19,942 sheep, and 18,338 swine. There were 5 manufactories of carriages and wagons, 2 of wrapping paper, 1 of sashes, doors, and blinds, 2 of woollen goods, 5 brick kilns, 13 flour and 23 saw mills. Capital, Delphi. **XII.** A N. W. county of Illinois, separated from Iowa on the W. by the Mississippi river; area, 416 sq. m.; pop. in 1870, 16,705. The surface is rolling, and divided between prairie lands and forests, and there are extensive lead mines. It is traversed by the Western Union railroad. The chief productions in 1870 were 418,333 bushels of wheat, 25,721 of rye, 1,367,965 of Indian corn, 775,100 of oats, 123,466 of barley, 133,949 of potatoes, 25,610 tons of hay, 532,486 lbs. of butter, and 32,659 of wool. There were 9,813 horses, 7,984 milch cows, 14,613 other cattle, 7,342 sheep, and 26,213 swine. There were 6 manufactories of carriages and wagons, 10 of saddlery and harness, 2 of malt liquors, 9 flour and 2 saw mills. Capital, Mt. Carroll. **XIII.** A W. central county of Iowa, drained by North and Middle Raccoon rivers, and the West Nishnabotunga; area, about 600 sq. m.; pop. in 1870, 2,451. The climate is healthy and the soil fertile. Coal, iron, building stone, and timber are abundant. The Chicago and Northwestern railroad passes through

it. The chief productions in 1870 were 65,758 bushels of Indian corn, 12,525 of oats, 68,830 of wheat, and 2,189 tons of hay. There were 745 horses, 503 milch cows, 1,107 other cattle, and 1,528 swine. Capital, Carrollton. **XIV.** A N. W. central county of Missouri, lying between the Missouri river on the W. and Grand river on the E.; area, 700 sq. m.; pop. in 1870, 17,446, of whom 827 were colored. The surface is somewhat uneven, and in many places is covered with thick forests of oak, black walnut, and other trees. The soil, which rests on beds of limestone and sandstone, is generally productive. The western division of the North Missouri railroad traverses it. The chief productions in 1870 were 233,069 bushels of wheat, 1,205,966 of Indian corn, 192,829 of oats, 4,986 tons of hay, 186,278 lbs. of butter, 41,821 of wool, and 256,578 of tobacco. There were 7,542 horses, 1,787 mules and asses, 5,729 milch cows, 10,407 other cattle, 17,171 sheep, and 34,499 swine. There were 4 manufactories of saddlery and harness, 3 of tin, copper, and sheet-iron ware, and 7 flour mills. Capital, Carrollton.

CARBOLL, Charles, of Carrollton, a patriot of the American revolution, the last surviving signer of the Declaration of Independence, born at Annapolis, Md., Sept. 20, 1737, died Nov. 14, 1832. In 1745 he was taken to the college of English Jesuits at St. Omer, France, where he remained six years, and then went to the Jesuit college at Rheims. After two years he went to Bourges to study the civil law, and after remaining there one year spent the next two in Paris, whence he repaired to London and began the study of law in the Temple. In 1764 he returned to America, and in 1768 married Mary Darnell. He inherited a vast estate, the last of the manorial grants of Maryland, and at the commencement of the revolutionary war was considered the richest man in the colonies, his property being estimated at \$2,000,000. In 1770-'71 he wrote articles, under the signature of "The First Citizen," against the right of the government to regulate fees by proclamation. In 1775 he was chosen a member of the first committee of observation established at Annapolis; and during the same year he was elected a delegate to the provincial convention. In February, 1776, he was appointed one of the commissioners to proceed to Canada in order to induce the inhabitants of that country to unite with the colonies. He returned in June, and on the 12th presented their report. He found the declaration of independence under discussion, and the delegates of Maryland shackled by instructions "to disavow in the most solemn manner all design in the colonies of independence." He hastened to Annapolis to procure a withdrawal of these instructions. Together with Judge Chase, he labored so assiduously that on June 28 the instructions were withdrawn and the delegates authorized to join in a declaration of independence. On July 4, 1776, he was appointed a delegate to congress,

and on Aug. 2, when the declaration was first formally signed, he was one of the earliest signers. As he affixed his signature a member observed, "There go a few millions;" and adding, "however, there are many Charles Carrolls, and the British will not know which one it is," Mr. Carroll immediately added to his name "of Carrollton," and was ever afterward known by that title. He took his seat July 18, and was soon afterward placed in the board of war. In the latter part of 1776 he was one of the committee to draft the constitution of Maryland, and in December of the same year he was chosen to the senate of that state. In 1777 he was reappointed a delegate to congress. In 1781 and 1786 he was reelected to the Maryland senate, and in 1788 chosen a United States senator. In 1797 he was again elected to the senate of Maryland, and in 1799 he was appointed one of the commissioners to settle the boundary line between Virginia and Maryland. In 1810 he retired from public life, and afterward devoted his time to the management of his estate. On July 4, 1821, the fact that only four of the signers of the Declaration of Independence were still living was noticed in many of the newspapers. Of these, William Floyd of New York died 30 days afterward. The death of John Adams and Thomas Jefferson on July 4, 1826, left Charles Carroll of Carrollton the last surviving signer. In the performance of their obsequies, funeral honors being paid them in Baltimore as in many other cities, Mr. Carroll was chief mourner. On July 4, 1828, after he had passed the age of 90 years, in the presence of a vast concourse of spectators and attended by an imposing civic procession, he laid the corner stone of the Baltimore and Ohio railroad.

CARROLL, John, an American prelate, born at Upper Marlborough, Md., in 1735, died Dec. 3, 1815. He was educated in the colleges of St. Omer and Liège, at the latter of which he was ordained a priest, and after surrendering his patrimonial estate to his brother became a member of the society of Jesus. Upon the dissolution of that society in France in 1762, he acted as the secretary of the dispersed fathers in their remonstrance with the court of France respecting the temporal interests of the order. He then went to England, and was selected by a Catholic nobleman to accompany his son as tutor in a tour of Europe. On his return to the continent in 1773, he was for a short time professor at Bruges and afterward retired to England, living with the family of the earl of Arundel. On the breaking out of the troubles between Great Britain and the American colonies, he returned to America, and was invited by a special resolution of congress to accompany his cousin, Charles Carroll of Carrollton, Dr. Franklin, and Samuel Chase on a political mission to Canada, from which it was hoped that great benefits would ensue to the colonial cause. After the establishment of peace the Roman Catholic clergy of the United

States petitioned the pope for the establishment of a hierarchy in this country, and at Dr. Franklin's instance Mr. Carroll was appointed vicar general in 1786, when he fixed his abode in Baltimore. In 1789 he was appointed the first Catholic bishop in the United States. He was consecrated in England, assuming the title of bishop of Baltimore; and in 1815, shortly before his death, he was created archbishop.

CARRON, a small river of Scotland, 14 m. long, rising between the friths of Forth and Clyde, and flowing into the frith of Forth, about 8 m. N. of Falkirk. About half a mile from the stream, near Falkirk, is the battle ground where the English defeated Wallace in 1298. The Carron was the boundary of the Roman empire, the wall of Antoninus running close to and parallel with it for several miles. In the early part of the 5th century many battles between the Romans and the Scots and Picts were fought near this river. The village of Carron, on its banks, is known for its large iron works, established in 1760, at which the kind of cannon called carronades was first constructed in 1779.

CARROT (*daucus carota*, Tourn.), a plant of the natural order *umbellifera*, or parsley family. It is a biennial, bearing seeds on stems 2 to 2½ ft. high, in clusters called umbels. It may be seen growing in its wild state in pastures, where it is a great pest. The tap root of the domesticated carrot is raised from seeds sown in cultivated ground, and has long been used in soups and stews, and is a favorite in Germany and France. It is a promoter of digestion, and is especially valued as a substantial food for horses and other stock. Butter of an excellent quality and bright color can be made by feeding a peck of carrots morning and night to each milch cow. They can be raised at the rate of 500 to 1,500 bushels per acre. The best soil is a deep dry loam, rich from previous manuring. The carrot germinates slowly, requiring about three weeks before it appears above ground. This slow growth allows the weeds time to start, and makes culture more expensive. To avoid this, it has been the practice with many to drill radishes, mustard, or oats with them, to mark the rows at an early period so as to allow the spaces between the rows to be cleaned, even before the plants are up. Some growers place the seed in a bag, and bury it in the earth until it begins to swell and show signs of sprouting, when it is rolled in plaster and planted. The amount of seed required is 2½ to 4 lbs. per acre, depending on nearness of drills; if radishes are sown with them, an equal bulk will be required. Early carrots for house use are sown as soon as the soil is fit to receive the seed. Field carrots do better, sown from May 10 to June 10. In England carrots are best grown on ridges, but in our warm climate flat culture is to be preferred. In gardens they are sown in drills 15 to 20 in. asunder, and cultivated by hand. In the field they are planted from 24 to 30 in. apart, grown

more thickly in the drill, and tilled by horse power. The land is deeply ploughed, subsoiled, smoothly harrowed, and rolled. The seed is sown from a drill barrow at a depth of one half to three quarters of an inch. Some drilling machines sow a special manure with the seed, which is advantageous in giving the plants an early start. Should any manure be required, it would be advisable to use soluble special manures, made with regard to the wants of the plant and the deficiencies of the soil. The best Peruvian guano, mixed with many times its bulk of muck or charcoal dust, will answer a good purpose if ploughed in the soil before planting; 300 to 500 lbs. per acre will be required for a good dressing. Soluble superphosphate of lime, with about one third its weight of guano, probably forms one of the best general manures for carrots. Ten bushels of common salt per acre will add to its value; and on most soils 25 or 50 bushels of unleached wood ashes dressed over the surface separately from and after the other manures, so that they will not come in immediate contact with the ashes, will increase the yield. After-culture consists in frequent stirring of the soil with a horse hoe, root cleaner, or other similar instrument, which cuts close to the plant, and demolishes all weeds in spaces between the rows. In November the crop is lifted, by running a subsoil lifter close to a row of carrots at full depth, say 10 to 20 inches; this will loosen the whole soil, and the roots may be readily pulled, the tops removed with a knife, fed to the cattle, or left on the ground to be ploughed under for manure, while the roots are stored in a cool cellar, where an even temperature just above freezing is maintained; or they may be pitted in long narrow piles in the field, covered with two or three inches of long rye straw and several inches in depth of earth, leaving straw chimneys to ventilate the pits. When fed to cattle, they should be washed in clean water, and cut in thin slices, and given alone or with other food. The meal for fattening cattle should be sprinkled over carrots.

CARSON, Christopher, popularly known as **KIR CARSON**, an American mountaineer, trapper, guide, and soldier, born in Madison co., Ky., Dec. 24, 1809, died at Fort Lynn, Colorado, May 23, 1868. While he was yet an infant his family emigrated to what is now Howard co., Mo. At 15 years of age he was apprenticed to a saddler, with whom he continued two years. The next eight years of his life were passed as a trapper, which pursuit he relinquished on receiving the appointment of hunter to Bent's fort, where he continued for eight years more. He was then engaged by Fremont as guide in his explorations. In 1847 he received an appointment as lieutenant in the rifle corps of the army. In 1853 he drove 6,500 sheep to California, a difficult but successful undertaking. On his return to Taos he was appointed Indian agent in New Mexico, and was instrumental in bringing about many treaties with

the Indians. During the civil war he rendered important services in New Mexico, Colorado, and the Indian territory, rose to the rank of colonel, and was brevetted brigadier general. He died from the rupture of an artery in the neck.—See "Life of Kit Carson," by Charles Burdett (Philadelphia, 1869).

CARSON CITY, the seat of justice of Ormsby co., Nevada, and capital of the state, situated in Eagle valley, 4 m. from Carson river, and 178 m. N. E. of San Francisco; pop. in 1870, 3,042, of whom 697 were Chinese. It is in a fertile and picturesque region. The Sierra Nevada mountains rise abruptly on the west, while the valley of the Carson extends far to the north and east. A railroad connects it with Virginia and Gold Hill, in Storey co., which is used chiefly to transport ore from the mines at those places to the crushing mills on the Carson river, and to carry back timber, which is abundant on the slopes of the Sierra Nevada. The state house is in course of construction. The branch mint occupies a fine building. The deposits of bullion for the year ending June 30, 1872, amounted to \$8,564,436 69, of which \$4,371,573 55 were gold, and \$4,192,863 14 silver. The total deposits of gold to that date were \$5,499,537 59. The total coinage, including silver bars, has been 441,449 pieces, valued at \$10,881,428 13, of which 77,029 pieces, valued at \$874,461 05, were gold, and 364,420 pieces, valued at \$10,006,607 08, were silver. The state prison is at Warm Springs, 2 m. to the east. There are four quartz mills, with 76 stamps, for the production of silver, and several churches, good schools, two daily newspapers, and the state and odd fellows' libraries. Carson City was founded as a ranch before the discovery of silver in Nevada, after which time it increased rapidly, being on the line of travel through the state previous to the opening of the Central Pacific railroad.

CARSTAIRS, or **Carstares**, **William**, a Scottish divine, born at Cathcart, near Glasgow, Feb. 11, 1649, died Dec. 28, 1715. He was educated at Edinburgh and Utrecht, devoted himself warmly to the prince of Orange, and became minister of an English church at Leyden. After returning home, he took offence at the conduct of the Episcopal party, through whose influence he was arrested, after which he retired again to Holland. He was brought back on a charge of having been accessory to the Rye House plot, and put to the torture in 1682. Being dismissed, with the king's pardon, he again went to Holland, where he rose still higher in favor with the prince of Orange, who made him his chaplain in 1685; and as King William's chaplain and confidential secretary, 1688-1702, he contributed much to the establishment of the Presbyterian government in Scotland. During the reign of Anne he still retained his chaplaincy. In 1704 he became professor of divinity at Edinburgh, and was four times moderator of the general assembly.

CARSTENS, Asmus Jakob, a German painter, born at Sanct Jürgen, near Schleswig, May 10, 1754, died May 26, 1798. He was a miller's son, and had a youthful passion for painting, but was placed in a mercantile house. After quitting his master he went to Copenhagen, where he supported himself for seven years by taking portraits in red chalk, producing during the time a large historical picture, the "Death of Æschylus," and another painting, "Æolus and Ulysses." In 1783 he started for Rome, but his means did not permit him to go beyond Mantua, where he remained a month and then went to Lübeck, where he lived five years in obscurity. He was then introduced by the poet Overbeck to a wealthy patron, by whose aid he went to Berlin, where his "Fall of the Angels," a colossal picture, containing over 200 figures, gained him a professorship in the academy of fine arts. Two years' labor in Berlin and a travelling pension enabled him in 1792 to go to Rome, and study the works of Michel Angelo and Raphael. Afterward he spent some time in Dresden, studying the works of Albert Dürer. His best works were designs in aquarelle and paintings in fresco; he rarely painted in oil. His biography was published in 1806 (new ed. by Riegel, 1867), and his works, engraved by Müller, in 1869.

CARTAGENA, or *Carthagera* (anc. *Carthago Nova*, New Carthage), a seaport town of Spain, in the province and 29 m. S. S. E. of Murcia;

lat. $37^{\circ} 36' N.$, lon. $0^{\circ} 56' W.$; pop., including suburbs, about 60,000. It is built at the head of a deep, well sheltered harbor, flanked by steep hills, defended by works at its mouth, and forming one of the best ports on the Mediterranean. The town itself is walled and neatly built; the streets are wide, regular, and relieved by several public squares. It is the seat of a bishop, and has an old cathedral, of little beauty, and now a simple church. There are several other churches, convents, hospitals, an observatory, an artillery park, a splendid arsenal, barracks, dock yards, founderies, ropewalks, and a glass factory. Notwithstanding its commodious port, the town has little commerce. The inhabitants are employed chiefly in lead and silver mining, fishing, and exporting barilla, grain, and esparto. The mineral wealth of the neighborhood was known in very early times, and the yield of silver enabled Hannibal to carry on his war against the Romans. The mine of La Carmen was opened in 1839, and the veins have since been successfully worked by a joint stock company.—Cartagera was founded by Hasdrubal, the Carthaginian general, about 230 B. C.; was taken by Scipio in 210, at which period, Livy states, it was one of the richest cities in the world; was almost destroyed by the Goths; rose to great importance in the time of Philip II., and became the great naval arsenal of Spain. It was formerly very unhealthy; but within a few years the draining of the Al-

Cartagera, Spain.

majar, a lake formed by the rains, has remedied this, and its population has in consequence considerably increased.

CARTAGENA, a fortified maritime city of the United States of Colombia, capital of a province of the same name and of the state of Bolivar, 410 m. N. N. W. of Bogotá; lat. $10^{\circ} 25' N.$, lon. $75^{\circ} 30' W.$; pop. about 8,500. It is situated on an island beside the coast of the Caribbean sea, joined to the mainland by a series of artificial isthmuses, and to its suburb Jejemani by a wooden bridge. Both the city and suburb are surrounded by freestone fortifications, and on the mainland is an eminence 150 ft. high, which is, however, overlooked by the summit of Mount Popa, 550 ft. above the level of the sea, and not fortified, although it has repeatedly served as a successful point of attack against the city. The streets are nar-

row, the widest not being over 30 ft. broad, but regular, with paved or flagged sidewalks, and lighted with gas. The houses are of stone and well built; the majority have but one story. There are numerous public edifices of some beauty, especially the churches of Santo Domingo and San Juan de Dios (both bomb-proof); the monasteries of Santa Teresa and Santa Clara; that of Nuestra Señora de la Popa, on the mountain of the same name; and the cathedral, which is noteworthy for its magnificent marble pulpit. Cartagera has a college, a naval school, a hospital, a theatre, &c. The port is one of the best on the N. coast of South America, and the only one in Colombia in which vessels can be repaired. The bay is divided into three sections: Boca Grande and Pascaballos, with a mean depth of 15 fathoms; Boca Chica, somewhat deeper, and defended

Cartagena, Colombia.

by two strong castles; and the Caldera, as deep as the first, and thoroughly sheltered. The entrance to the bay is rather difficult; the tides are extremely irregular, and the roadstead for large vessels is distant nearly 3 m. from the city. The excessive heat is somewhat tempered by frequent sea breezes. The climate is not extremely insalubrious, especially in the dry season from December to May; but yellow fever epidemics at times commit fearful ravages, and leprosy is not uncommon. The *lomba*, a disease closely resembling yellow fever, in 1872 carried off 6,000 victims in the course of a few months. Mosquitoes are very large and troublesome; and a small insect, the *comejen*, may destroy in a single night whole packages of silk, woollen, or linen fabrics. Maize, rice, beans, peanuts, yuca, and tobacco are produced in abundance, with plentiful supplies of cabinet and other woods, and various species of gums, medicinal plants, &c. The exports to the United States are tolu, caoutchouc, vegetable ivory, mora, hides, and some other commodities. Delicious fish are taken in the bay, which is besides remarkable for enormous turtles, and for the number, voracity, and hideous appearance of the sharks found in it.—Cartagena was founded by the Spaniards in 1533, and fortified at a cost of \$29,000,000. In 1544 it was seized by the French; it was taken by Sir Francis Drake in 1585, and again by the French in 1697. Admiral Vernon unsuccessfully besieged it in 1741. In 1815 it was taken by Bolivar, again surrendered to the royalists the same year, and was finally retaken by the republicans Sept. 25, 1821.

CARTAGO, an inland city of the United States of Colombia, in the state of Cauca, on the right bank of the river Cauca, 130 m. W. of Bogotá, for the trade of which city it is the entrepot; pop. about 8,000. It is situated at a slight elevation above the Cauca, and 3,500 ft. above the level of the sea. The streets are wide and well laid out, but poorly lighted; the houses are well built; and the surrounding country is exceedingly picturesque and highly cultivated. Cartago has a cathedral, two parish churches, and a Lancasterian and some other schools. Considerable droves of horned cattle and swine are raised in the neighbor-

hood; the various tropical fruits, sugar, cacao of superior quality, coffee, and tobacco, are abundantly produced, and form, with swine and jerked beef, the chief articles of export. The city was founded by the Spaniards in 1540, between the rivers Otan and Quindiu, and was at the end of the same century transferred to its present site.

CARTAGO, an inland town of Costa Rica, on the right bank of the river of the same name, 13 m. E. N. E. of San José. This town, once a populous and prosperous emporium, and the residence of the federal authorities, was almost swallowed up, Sept. 2, 1841, by an earthquake which left standing only 100 out of 3,000 houses, and one out of seven churches. The commercial importance of the place has ever since been on the decrease, and the population has dwindled to about 5,000, owing in part to the decrease of the Indians, who mainly form the working class. Near the town is an extinct volcano 11,480 ft. high.

CARTE, Thomas, an English scholar, born near Clifton, Warwickshire, in April, 1686, died near Abingdon, Berkshire, April 2, 1754. He studied at Oxford and Cambridge, received holy orders, and was appointed reader of the Abbey church at Bath. A sermon which he preached in January, 1714, in which he endeavored to vindicate Charles I. with regard to the Irish rebellion, engaged him in a controversy with Dr. Chandler and led to his first publication, entitled "The Irish Massacre set in a Clear Light." On the accession of George I. he declined taking the oath of allegiance, and therefore relinquished his ecclesiastical office. In 1715 he was suspected of being implicated in the rebellion, and was obliged to conceal himself at Coleshill. Having officiated as curate in that town for a short time, he became secretary to Bishop Atterbury. In 1722 he was strongly suspected of being concerned in the bishop's conspiracy, and a reward of £1,000 was offered for his apprehension; but he escaped into France and remained there 12 years under the assumed name of Phillips, until Queen Caroline obtained permission for him to return to England. In 1744 he again gave umbrage to the government, and was arrested, but soon discharged. His principal works consist of the

chief materials for an English edition of De Thou and Rigault (7 vols., London, 1733); a "Life of James, Duke of Ormond" (London, 1735-'36); and a "History of England" (4 vols., 1747-'55), which brings the history down to 1654; the manuscript for the remainder, to 1688, is preserved in the Bodleian library.

CARTER, I. A N. E. county of Tennessee, bordering on North Carolina, drained by affluents of Holston river, and by Doe river; area, about 350 sq. m.; pop. in 1870, 7,909, of whom 573 were colored. It occupies some of the highest ground in the state. The Iron mountain range, covered with timber and rich in mines of iron, extends along its S. E. border. Watauga river and other streams supply water power, which is extensively employed in iron works. The valleys are highly productive. A branch of the East Tennessee, Virginia, and Georgia railroad traverses the county. The chief productions in 1870 were 37,169 bushels of wheat, 132,097 of Indian corn, 63,396 of oats, and 2,155 tons of hay. There were 1,033 horses, 1,326 milch cows, 2,543 other cattle, 5,430 sheep, and 7,253 swine. There were 6 iron forges, 1 flour mill, and 1 manufactory of woollen goods. Capital, Elizabethtown. **II.** A N. E. county of Kentucky, intersected by the Little Sandy river and Tygert's creek; area, about 500 sq. m.; pop. in 1870, 7,509, of whom 100 were colored. The surface is hilly and broken. The soil near the rivers is tolerably fertile, but in other places unfit for cultivation. The mineral wealth is considerable, iron ore and stone coal being found among the hills in great quantities. The Elizabeth, Lexington, and Big Sandy railroad is to traverse the county. The chief productions in 1870 were 13,214 bushels of wheat, 282,691 of Indian corn, 41,507 of oats, 107,529 lbs. of butter, and 17,175 of wool. There were 1,805 horses, 1,747 milch cows, 2,892 other cattle, 8,614 sheep, and 7,988 swine. There were 2 manufactories of pig iron. Capital, Grayson. **III.** A S. E. county of Missouri, intersected by Current river; area, 500 sq. m.; pop. in 1870, 1,455, of whom 30 were colored. The surface is diversified by hills and valleys. Timber is plentiful, and copper and iron are found. The chief productions in 1870 were 4,992 bushels of wheat, 73,259 of Indian corn, 7,311 of oats, and 28,550 lbs. of tobacco. There were 417 horses, 470 milch cows, 1,047 other cattle, 1,182 sheep, and 3,589 swine. Capital, Van Buren.

CARTER, Elizabeth, an English authoress, born at Deal, Dec. 16, 1717, died in London, Feb. 19, 1806. She translated Epictetus (London, 1758), and also wrote some poems for the "Gentleman's Magazine," numbers 44 and 100 of the "Rambler," and published a volume of poems in 1738. Her poetical works exhibit much tenderness, simplicity of sentiment, and expressive sweetness. She never married.

CARTERET, an E. county of North Carolina, bordering on the Atlantic and Pamlico sound; area, 450 sq. m.; pop. in 1870, 9,010, of whom

2,725 were colored. Several long, narrow islands, on one of which is Cape Lookout, partially separate it from the sea, and Newport river flows through it. The surface is level, and much of it is occupied by swamps and pine forests. The Atlantic and North Carolina railroad passes through it. The chief productions in 1870 were 32,260 bushels of Indian corn, 58,715 of sweet potatoes, and 774 bales of cotton. There were 542 horses, 935 milch cows, 1,970 other cattle, 1,099 sheep, and 3,765 swine. There were 2 saw mills and 4 manufactories of tar and turpentine. Capital, Beaufort.

CARTERET, Philip, an English navigator, was captain of the *Swallow* in the expedition commanded by Samuel Wallis, which sailed Aug. 22, 1766, on a voyage of discovery to the South seas; but he parted from Wallis's vessel, the *Dolphin*, and made a separate expedition. He discovered Queen Charlotte's isles, and other islands, two of which he called Gower and Carteret. He returned to England Feb. 20, 1769, and a description of his voyage was given by Dr. Hawkesworth in the introduction to his narrative of Capt. Cook's first voyage.

CARTESIUS. See DESCARTES.

CARTHAGE (called by the Carthaginians *Karthadtha*, the new city; the *Carthago* of the Romans, *Καρχηδών* of the Greeks), an ancient city and state in the north of Africa. The city, near the site of modern Tunis, on a peninsula which extends into a small bay of the Mediterranean, was founded, according to the legend, by Dido, a Phœnician princess, about 880 B. C. Of the early history, first settlement, and chronology of Carthage, beyond the fact that the original colonists were Phœnicians from Tyre, nothing definite is known; and ancient writers materially differ as to the date of the foundation of the city. Probably it was older, as at one period it was more important, than its rival Rome, and soon after its settlement it became very populous by the influx of Africans who came thither for traffic. How long Carthage remained under a monarchy, or what events occurred in its early history, is unknown, at least for a period of 300 years; but from the beginning it was an important maritime and commercial city, with a trade extending to all the ports in the Mediterranean, and inland to the Nile and to the Niger. Beyond the straits of Hercules the commerce of Carthage reached to the W. coast of Africa, to northern Europe, and even, it is supposed, to the Azores. About 508 B. C. the Carthaginians made a treaty with the Romans, relating mainly to commerce; and by this treaty (whose genuineness is contested by modern scholars), which Polybius (iii. 22, 26) translated from the original brazen tablets in the capitol, it appears that Sardinia and a part of Sicily were then subject to Carthage. It gradually extended its supremacy over all the islands in the western half of the Mediterranean. Its foreign trade was mainly a monopoly, which the treaty with Rome shows it meant to maintain. Beyond her commercial importance, and

later in history something of her successes and reverses in war, less is known of Carthage than of any other nation of antiquity. She has left no literature, no monuments, no traces of her people or her language, with the exception of a few inscriptions on coins, and a few verses in one of the comedies of Plautus. Even among the writers of nations with whom she carried on commercial business and waged wars, the notices of her polity, population, religion, manners, and language are few and far between; and the Romans are charged with destroying the Punic archives for three centuries. Although the waters of every sea were white with her sails, and the shores of every land, hospitable or inhospitable, civilized or savage, were planted with her colonies or frequented by her mariners, no relic of her laws, language, or blood remains. Were it not for the wars which terminated her existence as a nation and a people, we should scarcely be aware of the existence of a city the inhabitants of which had visited the Western isles, the Canaries, and the Cape Verdes; had braved, if they had not actually crossed, the waters of the Atlantic; and had excavated the tin mines of Cornwall. Even of the Carthaginians in their wars we know little, and this is by the names and the deeds of her generals, several of whom were among the greatest of antiquity, not by the constitution, composition, or character of her armies. Through Aristotle and Polybius we have learned something of her political system and her government, and a little of her religion. Of her civic customs, social habits, domestic institutions, amusements, and industry, with the exception of some few hints in relation to her navigation, commerce, and agriculture, we are ignorant. No writer has so concisely and ably brought together what is known of the great commercial republic of antiquity as Dr. Thomas Arnold, in his "History of Rome," from which a portion of the following is condensed. In the middle of the 4th century B. C. the Carthaginians possessed the northern coast of Africa, from the middle of the Greater Syrtis to the pillars of Hercules, a country reaching from lon. 19° E. to 6° W., and a length of coast which Polybius reckoned at above 16,000 stadia. In that part where the coast runs nearly N. and S. from the Hermæan headland or Cape Bon to the Lesser Syrtis was one of the richest tracts to be found; and here the Carthaginians had planted their towns thickly, and had covered the open country with their farms and villas. This was their *περιοικίς*, the immediate domain of Carthage, where fresh settlements were continually made as a provision for the poorer citizens; settlements prosperous, indeed, and wealthy, but politically dependent. Distinct from these settlements of the Carthaginians were the sister cities of Carthage, founded by the Phœnicians of Tyre and Sidon. Among these colonies were Utica, Hadrumetum, the two cities known by the name of Leptis (situated the one

near the western extremity of the Greater Syrtis, and the other on the coast, between the Lesser Syrtis and the Hermæan headland) and Hippo. These were the allies of Carthage, and some of them were at the head of small confederacies of states. In the beginning the Phœnicians in Africa occupied their forts and domains by sufferance, and paid tribute to the natives, as an admission that they did not own the soil. Subsequently the settlers became sovereigns. The natives were driven back from the coasts and confined to the interior, where they became mere tillers of the soil, and were subject to despotic rule, to severe taxation, and to conscription for service in the Carthaginian armies. Intermarriage of the settlers with the native women resulted in a race of half-castes, known as Liby-Phœnicians, or Afro-Phœnicians; and colonies of them were sent to the Atlantic coast of Africa, and probably of Spain also, beyond the pillars of Hercules. It is traditional that one voyage from Carthage was undertaken mainly to settle 30,000 Afro-Phœnicians on the African coast S. of the straits of Gibraltar. So early as the 7th century B. C. the trade of Carthage began with the Spanish seaports, especially with Tartessus or Tarshish. At the beginning of the 4th century B. C. the whole coast of Spain, both Atlantic and Mediterranean, was full of Carthaginian trading posts and settlements, mostly of small size and of little if any political importance. Sardinia and Corsica were both subject to Carthage, while on the shores of Sicily she had also strong fortresses, trading posts, seaports, and dockyards. From the natives of all these countries, as well as mercenaries from Gaul, Liguria, and the coasts of the Adriatic, were recruited the large and effective armies by which the Carthaginians maintained the quiet of their provinces, and pushed their foreign conquests.—The political constitution of Carthage is said to have resembled that of Sparta, in that it combined the elements of monarchy, of aristocracy, and of democracy. But it is difficult to ascertain exactly how they were combined, or which predominated, during the greater period of her existence. During her struggle with Rome the aristocratic element prevailed, and appears to have been an aristocracy mainly of commercial wealth, not of birth; although there was to a certain extent a hereditary nobility which furnished the two chief magistrates, variously called kings and suffetes, who formed originally the supreme and nearly despotic executive, as well as being leaders in war, but were reduced by successive usurpations of the nobility to functions and powers not differing essentially from those of the doges of Venice. Then there was a senate of 104 members, and also a council of 100 members. There seems to have been besides a pentarchy, who formed the highest magistracy. Davis conjectures that the senate had periodically five outgoing and five incoming members, and that those

whose term expired served for a period as a pentarchy, and could summon in times of perplexity 100 men for a select council. The multiplication of offices was a part of the system at Carthage; and the *suffetes*—a term identical with the Hebrew word which is rendered “judges” in the Scriptures—as well as the other principal magistrates, bought their dignities, so that high office was inaccessible except to the rich. The power of the commons was exceedingly small; they had neither originating powers nor judicial functions; yet, as ample provision was made for the poorer classes, and as the surplus population was always disposed of, profitably and advantageously to themselves, by a system of colonization at the government expense, the lower orders remained for many centuries contented with the constitution of their country. Polybius says that during her wars with Rome the constitution of the city became more and more democratic.—“The language of Phœnicia,” says Dr. Arnold, “was a cognate tongue with the Hebrew, if it were not, as is held by Gesenius and others of the best authorities, identical with the earliest Hebrew of the Old Testament, and varying from it no more than does the dialect of the later Hebrew writers. It is evident, however, from the fact that the Carthaginian tongue seems to have been nowhere studied by the inhabitants of the nations with whom they had treaties and constant commercial intercourse, even among the most learned men and the most distinguished scholars, that it could have contained little or nothing worthy of preservation.” Of their architecture and their arts we have as yet few relics and records. The houses of Carthage are believed to have been several stories high, of which the lower story alone was built of massive material, and the others were moulded, as Pliny says, of earth. When such buildings are pulled down, or decay, they are nothing but a heap of rubbish. The Romans rebuilt the city on top of this, and in digging their foundations they often cut through rich mosaic pavements and other ornaments of the lower stories of the original town. The mosaics recently excavated and considered relics of Punic Carthage are of exquisite workmanship. The city grew to be 23 m. in circuit, and had two harbors, an outer and an inner, the latter being surrounded by a lofty wall. Across the peninsula was a triple wall 3 m. long, and between the walls were stables for 300 elephants and 4,000 horses, and barracks for 2,000 infantry, with magazines and stores. Cothon, an island in the centre of the inner harbor, was lined with quays and docks for 220 ships. Above the city, on the western heights, was Byrsa, the citadel, as its Phœnician name signified, which, however, the Greeks identified with their *βύρσα*, hide, and thus formed their legend of the purchase of the spot on which the original town stood. (See DRDO.) When it surrendered to the

Romans 50,000 people marched out of it. On its summit was the famous temple of *Æsculapius*. At the N. W. angle of the city were 20 immense reservoirs, each 400 ft. by 28,

Carthaginian Cistern.

filled with water brought by an aqueduct from a distance of 52 m. The suburb Megara, beyond the city walls, but within those that defended the peninsula, was the site of magnificent gardens and villas, which were adorned with every kind of Grecian art; for the Carthaginians were rich before the Romans had even conquered Latium. The navy was the largest in the world, and in the sea fight with Regulus there were 350 ships, carrying 150,000 men. Modern excavations have led to the discovery of the groundwork of a temple, probably that of Cronos, or Baal Hamman, and the quantities of fragments of precious marbles found about it indicate that it must have been gorgeously decorated. Some of the Punic inscriptions that have come to light are wonderful for the proportion and exquisiteness of the characters. Of their religion we know from Scripture and from more recent history that it was a cruel and bloody superstition. They worshipped on high places, and they had sacred groves, as well as idols. Their principal god was Baal, Belsamen, or the bright one, considered by the Greeks as identical with Cronos or Saturn, and who in process of time became in some features assimilated to Apollo. He was evidently the fire god or sun god, and to him were offered the human sacrifices, of children more especially, who were placed on the extended palms of the metallic statue, whence they rolled into a fiery furnace. With the sun god was associated a female deity, Ashtoreth or Astarte, expressive probably of the productive power of nature under the generative power of the sun, and worshipped as the queen of heaven. The worship of Ammon was associated with that of Baal and of the sacred elephant; while that of Melkarth (*Melk-karth*, king of the city), the Phœnician Hercules, was celebrated by the lighting of yearly funeral pyres, and the release of an eagle, typical of the sun and of the legendary phœnix. The offering of human sacrifices extended as far westward as

to Cadiz, where there existed a temple and statue of Baal-Saturn.—The first period of the history of Carthage extends to the beginning of the war with Syracuse, from the commencement of the city, whenever that occurred, nominally about 880 to 480 B. C.; during which time she had conquered her African empire, Sardinia, and the adjacent isles; waged wars with Massilia and the Etrurians, on commercial grounds; prosecuted her voyages of discovery, traffic, and colonization along the coasts of Spain and far out into the Atlantic; established trading intercourse with the Scilly isles and parts of the British coast; and, as some believe, pushed her adventures so far as to the inhospitable shores of the Baltic, where she is reported to have collected amber. About 480 begins the second period of Carthaginian history. It opens with their efforts to conquer and attach to their empire the great, rich, and fertile island of Sicily, and closes in 264 with the outbreaking of the first Punic war. The Syracusan war was waged long and with various success. In the simultaneous attempt of the Persians on the Hellenic, and the Carthaginians on the Sicilian Greeks, the Carthaginians under Hamilcar were defeated at Himera, by Gelon, tyrant of Syracuse, and Theron of Agrigentum, with nearly as much loss as was their ally, Xerxes, at Salamis. Tradition says that of 300,000 Carthaginians, 150,000 were killed in battle or flight, and the rest were taken prisoners; while of 2,000 ships of war and 3,000 transports, 8 only escaped, and these were cast away, only a few men saving themselves in a small boat and carrying to Carthage the news of the total loss of the fleet and army. As a condition of peace the Carthaginians were compelled to pay 2,000 talents in silver, build two temples, and renounce human sacrifices in their Sicilian trading posts and settlements. In the war with Hiero, Gelon's successor, about 410, Hannibal, son of Gisco, conquered and held in occupation the cities of Himera, Selinus, and Agrigentum. With Dionysius they were for a short time at peace, and then employed themselves in consolidating their former conquests on the island, which were now very rich and strong, consisting of well fortified seaports, fortresses, dockyards, naval stations, and garrisons, backed by considerable territorial domains of great productiveness and wealth. After the reëstablishment of republicanism in the Greek cities by Timoleon, the Carthaginians were almost invariably unfortunate. Agathocles, however, on attempting the policy of Dionysius, to drive them out of the island, was defeated and besieged in his capital of Syracuse; but he broke out of the beleaguered city with a portion of his army, and carried the war into Africa. There he overran the open country, took 200 towns, and, although he was twice personally called back to Sicily to quell mutinies and restore order in his home dominions, actually maintained himself four entire years on African soil,

at the gates of Carthage. At length his fortune turned, his armies in Africa were obliged to surrender, and in the year 306 he concluded a peace which restored order to Sicily, and established both parties in possession of the territories each held before the breaking out of the war. After his death the Carthaginians increased their possessions and power in Sicily, and established themselves as actual masters and sovereigns of the Balearic isles, Corsica, Sardinia, and the Lipari islands, thus girding the whole Roman seaboard with a belt of insular fortresses. Thus far, however, all was peace and amity between the two great western republics of antiquity. Ten years after the retreat of Pyrrhus, the Romans were undisputed masters of Italy. Carthage had become yet more influential in Sicily, and was bent on converting influence and ascendancy into empire and possession. The little strait of Messina alone divided the possessions and separated the armed forces of the two powerful, ambitious, encroaching, and jealous states, and a contest between them was inevitable. It arose with the invocation of Roman aid by the Mamertines, belonging to an Italian city of Sicily, against the Carthaginians; this being gladly rendered, as by a people seeking pretext of war, gave birth to the first Punic war, which broke out in 264, and may be regarded as the commencement of the third period of Carthaginian history. This war lasted 23 years. It was waged (with the exception of the invasion, defeat, and capture of Marcus Regulus on Carthaginian territory) either on the island of Sicily or on the waters of the Mediterranean. On the latter, at first, the Romans suffered bloody defeats and maritime disasters. Still they persevered, and although when the war broke out they had not a ship of war, a mariner, or an officer who had seen sea service, in the end obtained the mastery of the Mediterranean, crushed the last fleet of the Carthaginians in a terrible conflict off the island of Favignana, at the W. angle of Sicily, and granted the peace which their enemy sued for, on condition that the Carthaginians should evacuate Sicily and all the isles thence to the Italian coast, release all Roman prisoners without exchange or ransom, and pay the expenses of the war, at the price of 3,200 Euboic talents, or \$3,337,888, within the space of ten years. (See HAMILCAR, and HANNO.) In the 22 years that followed before the commencement of the second Punic war, although the Carthaginians had lost Sardinia, of which the Romans, taking advantage of a mutiny of the Carthaginian mercenaries, made themselves masters, Carthage had more than repaired all her losses by the conquest and colonization of the vast and rich Spanish peninsula, with its virgin gold mines and its bold and hardy population, furnishing an inexhaustible supply of men to recruit the armies of the republic. Hannibal, the son of Hamilcar, forced the war by laying siege to Saguntum (now Murviedro),

an allied city of the Romans on the seacoast, and by crossing the Ebro contrary to protest, if not to treaty. The passage of Hannibal across the Alps, the victories of the Ticinus, the Trebia, Lake Thrasymene, and Cannæ, the defeat on the Metaurus and the death of Hannibal's brother-in-law Hasdrubal, the 16 Italian campaigns, the simultaneous victories of the Roman arms in Spain and Sicily, the transfer of the war to Africa by the elder Scipio Africanus, the defeat of Zama, and the total submission, subjection, and disarming of Carthage, are the principal incidents of the second Punic war, which continued about 18 years, and was concluded in 201 by the virtual subjection of Carthage. (See HANNIBAL.) An interval of 52 years followed, during which Rome encouraged her allies to commit aggressions on Carthage; until that city, in despair, went to war to repel unendurable insult and provocation, regardless of the late treaty which forbade them to take up arms against any nation without consent of the Romans. After this the Romans, as the price of peace, extorted from them all their remaining ships of war, all their arms, military engines, and supplies, compelled them to give 300 hostages, and then commanded them, as the only alternative by which to escape destruction, to abandon their city and seashore position, and to remove 10 miles inland. The third Punic war resulted, and for three years (149-146) the unarmed, almost defenceless citizens of Carthage maintained a warfare of despair. At the end of that space a second Scipio, the son of Paulus Æmilius, the conqueror of Perseus, adopted by the son of the conqueror of Hannibal, took the city by storm, and destroyed it, razing it to the ground, passing the ploughshare over its site, and sowing salt in the furrows, the emblem of barrenness and annihilation. The inhabitants fought from street to street, while the houses burned over their heads, during 17 days, until 55,000 persons, the whole of the survivors of a nation, were shut up in the ancient citadel called Byrsa, where they surrendered at discretion, and were all sold into slavery. Hasdrubal only, the commander, with his wife, children, and 300 Roman deserters, took refuge in the temple of Æsculapius, with the determination to defend themselves to the last, and die under the ruins of the last Punic edifice. The heart of the leader failed him, and while his wife and all his followers met the death from which he meanly shrank, he surrendered himself to be led in triumph, and to die by the hands of the Roman carnifex in the Tullianum. About 30 years after the destruction of Carthage, a portion of the city was temporarily restored, and called Junonia, by 6,000 colonists whom C. Gracchus brought over from Rome. Long afterward, in 46 B. C., Cæsar planted a small colony on the ruins of Carthage; and Augustus, his successor, built a city, of the same name, at a small distance, which attained some eminence. It became an important Christian

bishopric A. D. 215. Cyprian held a council there in 252. It was conquered by Genseric from the Romans in 439, and continued to be the seat of the African empire of the Vandals until it was retaken by Belisarius in 534. It was finally destroyed by the Saracens in the caliphate of Abd-el-Melek in 698.—See Böticher, *Geschichte der Karthager* (Berlin, 1827); Münter, *Religion der Karthager* (2d ed., Copenhagen, 1821); and Davis, "Carthage and her Remains" (New York, 1861). In connection with Phœnician antiquities, those of Carthage have been treated by Movers, Gesenius, and others.

CARTHEUSER, Johann Friedrich, a German physician and naturalist, born at Hayn, Sept. 29, 1704, died at Frankfort-on-the-Oder, June 22, 1777. He studied medicine first at Jena and afterward at Halle, where he took the degree of doctor in 1731. He was appointed in 1740 professor of chemistry, pharmacy, and materia medica at the university of Frankfort-on-the-Oder, and shortly afterward to the chair of anatomy and botany. Still later he was named professor of pathology and therapeutics. He was also appointed rector of the university, and continued to hold his appointments till his death. He was made member of the academy of sciences, Berlin, in 1758. His chief merit consists in having introduced the method of submitting the various substances of materia medica to a strict ordeal of chemical analysis. He analyzed a great number of plants and other substances, and gave an exact account of the elements which enter into their composition. He published a considerable number of books and dissertations, among which are: *Elementa Chymicæ Medicæ Dogmatico-experimentalis* (Halle, 1736); *Fundamenta Medicæ Generalis et Specialis* (2 vols., Frankfort, 1749-'50); and *De Morbis Endemicis Libellus* (Frankfort, 1772).

CARTHUSIANS, a branch of the religious order of the Benedictines, founded by St. Bruno in 1086. The first monastery of the order was built in a wild and solitary district six miles from Grenoble, in the department of Isère, known as La Chartreuse, whence the order took its name. The observances of the Carthusian monks were austere and penitential in an extraordinary degree, even among contemplative orders. They devoted a portion of their time to manual labor, consisting chiefly in the transcribing of ancient MSS. Their labors as agriculturists gained great renown for their name, for they reclaimed marshy and unhealthy neighborhoods, and caused the rocky and barren fastnesses of La Chartreuse and other desert regions to bloom with the fruits of patient and intelligent toil. They had rich and celebrated abbeys in England, France, and Germany. The Charterhouse in London was once a Carthusian monastery. The Certosa

of Pavia, and that of St. Elmo at Naples, are still visited by travellers, and for many years a Carthusian community occupied as a convent the baths of Diocletian at Rome. They de-

A Carthusian Monk.

clined rapidly at the close of the last century, and have not recovered in this. Since the suppression of religious houses in Italy the order is confined chiefly to the Grand Chartreuse and its filiations in France.

CARTIER, Sir George Étienne, a Canadian statesman, of the family of Jacques Cartier, born at St. Antoine, Sept. 6, 1814, died in England, May 20, 1873. He was educated at the seminary of St. Sulpice, Montreal, studied law, and in 1835 commenced practice in that city. In politics he became a follower of M. Papi-neau, and when the rebellion of 1837 broke out in Lower Canada, a price of \$2,000 was set on his head. He however escaped arrest, and in time an amnesty cast oblivion over the offence, and he lived to be entertained by Queen Victoria at Windsor castle. He was elected to the house of assembly from the county of Ver-chères in 1848. In 1856 he was appointed provincial secretary, and soon became attorney general. In November, 1857, he became leader of the Lower Canada section of the government, J. A. Macdonald being governor. After the provinces were confederated, and distinctions were conferred upon Canadians who had taken part in that change, Cartier considered himself slighted in being only created a commander of the bath while his colleague was knighted. Sir John Macdonald then advised the bestowal on Cartier of a higher title than that conferred on himself, and obtained for him a baronetcy. In August, 1858, Cartier became premier, with Macdonald for his chief Upper Canada colleague. He assisted in carrying the abolition of the feudal tenure in Lower Canada; in making the legislative council elective, and in that reactionary

measure which in 1867 reverted to the practice of crown nomination; in bringing about the codification of the laws of Lower Canada, and in judicial decentralization; and in originating and carrying out the confederation of British America. With the exception of an interval of about a year, he had held some cabinet office since 1858. In 1872 his health failed, and he visited Europe, without, however, resigning his office of minister of militia.

CARTIER, Jacques, a French navigator, born at Saint Malo, Dec. 31, 1494, died about 1555. Under the auspices of Francis I., he was intrusted with the command of an expedition to explore the western hemisphere. He sailed from Saint Malo, April 20, 1534, with two ships of 60 tons each, and a crew of 120 men, and in 20 days reached the E. coast of Newfoundland; thence steering N. he entered the straits of Belle Isle, and took possession of the coast of Labrador by planting a cross. He next turned S. and followed the W. coast of Newfoundland to Cape Ray, when he was borne W. by unfavorable weather toward the Magdalen islands. After visiting them, he continued W., landed at the mouth of the Miramichi, whence he went with some of his men to explore the bay of Chaleurs, and a few days later sailed with his two ships, to land again a little further N. in the bay of Gaspé, which he mistook for the outlet of a large river. He there had friendly intercourse with the savages, and inspired them with such confidence that one of their chiefs permitted two of his sons to go with him to France, on condition that he would bring them back the following year. There he planted another wooden cross, to which was attached a shield bearing the arms of his king, and the words, *Vive le roi de France!* He next proceeded N. E., doubled the E. point of Anticosti, and entering the channel which separates the island from the continent, sailed up that branch of the St. Lawrence to Mont Joly, not being aware, however, of the existence of the river. Returning, he reached Saint Malo, Sept. 5, 1534, after an absence of less than six months. This successful voyage encouraged the king to new efforts; three well furnished ships were fitted out for another expedition, which was joined by some of the young nobility of France, and Cartier was appointed commander, being designated in the commission as "captain and pilot of the king." About the middle of May, 1535, Cartier assembled his companions and men on Whit-Sunday, and repaired to the cathedral, where a solemn mass was celebrated, at which the whole company received the eucharist and the bishop's blessing. The squadron, consisting of La Grande Hermine, a vessel of 120 tons, La Petite Hermine, of 60, and L'Émérillon, a smaller craft, sailed May 19, carrying several young gentlemen as volunteers, and two chaplains. Storms soon separated the three vessels, which after a rough voyage arrived successively at their place of rendezvous, the inlet of Blanc Sablon, in the straits of Belle

Isle. On July 31 they sailed W. and entered the channel between the mainland and Anticosti, which he called Île de l'Assomption; sailed up the river St. Lawrence; saw the mouth of the Saguenay Sept. 1; and on the 14th came to the entrance of a river at Quebec, now called the St. Charles, to which he gave the name of Sainte Croix. The next day he was visited by Donnacona, of Stadaconé, *agouhanna* or king of Canada, with whom he was enabled to converse, the two Indians whom he had the previous year taken from Gaspé to France acting as interpreters. Leaving his two larger ships safely moored, he sailed in the *Emérillon* up the stream as far as Lake St. Peter; there, his further progress being interrupted by a bar in the river, he took to his boat with three volunteers, and on Oct. 2 arrived at an Indian settlement called Hochelaga, which he called Mont Royal, whence the present name Montreal. On the 5th he left Hochelaga and rejoined his ships at the mouth of the Sainte Croix, where he passed the winter. With his men he suffered from the severity of the climate, but above all from the scurvy, which made frightful ravages among them; no fewer than 25 soon died; and out of 110 still surviving in February, 1536, only a few were free from the disease. Owing to the reduction of their number, Cartier decided to abandon one vessel, apparently the *Petite Hermine*. After having taken solemn possession of the land in the name of Francis I., by erecting a cross bearing the arms of France, with the inscription, *Franciscus primus, Dei gratia Francorum rex, regnat*, he sailed May 6, carrying with him Donnacona and nine other chiefs whom he had somewhat treacherously kidnapped; went through the channel S. of Anticosti, and the straits S. of Newfoundland, and once more reached Saint Malo, July 16, 1536. The hardships which had been incurred during the expedition were not encouraging to colonization; but at last the entreaties of François de la Roque, lord of Roberval in Picardy, prevailed; he was appointed viceroi and lieutenant general of the new territories, while Cartier preserved the title of captain general and chief pilot of the king's ships. Five vessels were now fitted out; Cartier sailed with two of them, May 23, 1541; he was soon joined by the three others, and they arrived at Sainte Croix Aug. 23. On exploring the neighboring country, Cartier found a better harbor at the mouth of the Cap Rouge river, where he built a fort called Charlesbourg Royal. Here he anchored three of his ships, while the two others returned to France after landing their cargoes. Cartier then visited Hochelaga for the second time, with the particular purpose of ascertaining the obstructions to further navigation. The winter passed in gloom. Toward the end of May, 1542, nothing having been heard from Roberval, provisions becoming scarce, and the savages evincing unfavorable feelings, Cartier sailed for France. On his

way he met Roberval; but he continued, steering for France, where he arrived without any further accident. In the autumn of 1543 he made his fourth voyage to Canada, sent by the king to bring back Roberval, who had wintered at Charlesbourg Royal or France Roi, as he called it. Cartier wintered in Canada, and finally left it about May, 1544. From that time he lived quietly, either at Saint Malo or at the village of Limoilon; the precise date of his death is unknown. A brief but interesting account of his second expedition appeared anonymously in 1545. The journals of the first two journeys of Cartier are inserted in vol. iii. of Ramusio's Italian collection (Venice, 1565); also abridged in Marc Lescarbot's *Histoire de la Nouvelle France*; a French translation of Ramusio's account of the first voyage was printed at Rouen in 1598, and reprinted in 1865; and the journals appeared in the original French in 1867. A description of his third journey is in vol. iii. of Hakluyt's "Principal Navigations," &c. (1600). The whole series have been collected by the Quebec historical society.

CARTILAGE, a firm, elastic substance, of an apparently homogeneous structure, bearing some analogy to bone, and entering largely into the composition of the animal skeleton; in its intimate structure it approaches very closely the cellular tissues of vegetables. It constitutes the rudimentary skeleton of the higher mollusca, and of the selachian fishes, hence called cartilaginous fishes; in man and the higher animals it forms the internal skeleton at the early periods of life, and is in all employed as a nidus for the development of bone. The organic basis of cartilage is a variety of gelatine called chondrine; this, like gelatine, in a watery solution solidifies on cooling, and may be precipitated by alcohol, creosote, tannic acid, and corrosive sublimate, and is not precipitable with ferrocyanide of potassium; but, unlike gelatine, it is precipitable with acetic and the mineral and other acids, with alum, persulphate of iron, and acetate of lead. True cartilage is of a white or bluish white appearance; fibro-cartilage is of a yellowish color, and exhibits a fibrous structure. Temporary cartilages supply the place of bone in early life, and gradually become ossified; for a considerable time after birth the ends of the long bones are composed chiefly of cartilage, and the extremities are not united to the shafts by bone until about the 20th year. Permanent cartilages are divided into two kinds, the articular and the membraniform; the skeleton of the selachians is also permanent cartilage. Articular cartilages cover the ends of bones entering into the formation of joints, either a thin layer between almost immovable bones, as those of the cranium, ilium, and sacrum, or incrusting the ends in the free-moving ball-and-socket and hinge joints. The membraniform cartilages have no relation to locomotion, but serve to keep open canals or passages by the mere force of their elasticity; such are the cartilages of the external ear, nose, edge of the

eyelids, Eustachian tube, and the air passages. The distinguishing characters of cartilage are elasticity, flexibility, and cohesive power; it is not easily broken, and will speedily resume its proper shape when bent by accident or design. These varieties of cartilage, except the articular, are covered with a fibrous perichondrium, analogous to the periosteum of bones, which serve as support to the blood vessels. The simplest form of cartilage consists of nucleated cells, large, ovoid, more or less flattened by their mutual contact; the diminutive nucleus, attached to the cell wall, contains a minute nucleolus; these cells are scattered irregularly in an intercellular substance, or hyaline matrix, which contains numerous granules, many of which, according to Hassall, must be regarded as the cytoblasts from which new cells are developed; the amount of this substance is greatest in the

Homogeneous Substance and Cells of Cartilage.

fully developed cartilage. In the condensed margin of true cartilage, the cells are compressed, with their long diameters parallel to the surface they cover; when ossification begins in temporary cartilage, the cells become disposed in rows, as described in the article BONE. In the articular cartilages the cells are arranged in small groups in an abundant hyaline matrix; they measure from $\frac{1}{800}$ to $\frac{1}{100}$ of an inch; in their deep portions these cartilages gradually blend with the bone, which dips unevenly into the substance of the cartilage. In the cartilages of the ribs the cells are larger than in any other, being from $\frac{1}{80}$ to $\frac{1}{40}$ of an inch in diameter; they often have a linear arrangement, and are imbedded in a very abundant intercellular substance, which sometimes presents a distinctly fibrous structure, though not resembling white fibrous tissues. In the membraniform cartilages, the cells are very numerous in proportion to the intercellular substance, which is so fibrous in its character in the external ear as to approach very near to fibro-cartilage; the ear of the mouse is a good specimen of this form, and presents in its central portion a series of six-sided cells arranged in layers one above the other, resembling, except in size, the transverse section of the pith of a plant. Cartilage is sometimes found as an accidental and diseased product. *Enchondroma* is a tu-

mor attached to bone, containing cells like those of cartilage, and others of a peculiar form resembling the lacunæ of bone. In the articulations, especially in the knee joint, loose rounded bodies are often found, of a cartilaginous consistence, frequently as large as the knee pan; these interfere with the motions of joints, and are sometimes removed by operation. The cartilage cells of reptiles are larger than those of fishes, being largest in the siren; in birds cartilage is very early converted into bone, so that they have very little of it except in the joints; the largest cells in the mammals, according to Mr. Quekett, are found in the elephant. Cartilage belongs to non-vascular substances, as considerable masses are found unpenetrated by a single vessel; articular cartilage is non-vascular, except in some diseased conditions when the presence of a few vessels seems to have been detected; temporary cartilage also, when in small mass, has no vessels, but when of considerable thickness the delicate extensions of the investing perichondrium penetrate it in a tortuous manner; the membraniform resemble the temporary cartilages in respect to vascularity. The nutriment of articular cartilage is derived from the vessels of the joint, and from the synovial membrane, though none of these enter its substance, the nutrient material passing from cell to cell by imbibition; in cartilages of ossification vessels regularly appear, accompanying the process of bone formation. According to Hassall, cartilage cells are multiplied in two ways: 1, by the division of a single cell into two or more parts, each becoming a distinct cell; 2, by the development of cytoblasts in the intercellular substance, or in the parent cells, constituting a true reproduction, constantly going on. In this multiplication by division, and by development of secondary in parent cells, cartilages resemble the *algæ*, and herein they stand alone in the animal economy. Cartilage cannot be regenerated; fractured surfaces are united only by a condensed cellular tissue.—There is a form of tissue which may be described here, as it differs from cartilage chiefly in having its intercellular substance replaced by white fibrous tissue; it is therefore called fibro-cartilage. It occurs principally in the joints, where its strength and elasticity are most needed. Its color is white, slightly tinged with yellow, with the shining fibres of the white fibrous tissue quite conspicuous; its consistence varies from pulpy to very dense. The fibres are arranged in an intricate and interlaced manner, strongest in that direction in which the greatest toughness is required. To the strength of fibrous tissue is added the elasticity of cartilage; its vessels are few and derived from adjacent textures, and no nerves have been detected in it; its sensibility is low, and it has no vital contractility. The disks between the vertebræ are fibro-cartilage; their elasticity diminishes the shocks to which the spinal column is necessarily subjected; in the whale

these disks are very large, detached from the vertebral bodies, and more or less ossified. In the diarthrodial joints, as in the sterno-clavicular, temporo-maxillary, and knee joints, there are fibrous laminae, free on both surfaces, called *menisci*; in these the circumference is fibro-cartilage, and the centre more cartilaginous. On the edges of the shoulder and hip joints is a rim of fibro-cartilage, giving depth to the articular cavities. In the grooves in bone for the lodgment of tendons we find another instance of the occurrence of fibro-cartilage. Fibro-cartilage is not so prone to ossification as the simple fibrous structures; it is repaired by a new substance of similar texture; in cases of false joint from the non-union of fractured bone, the broken ends are sometimes connected by fibro-cartilage. The pubic bones at the symphysis are united by this tissue. Fibro-cartilage is less soluble in boiling water than true cartilage, and yields therefore less chondrine.—The uses of cartilage and fibro-cartilage are entirely of a mechanical nature; their structure is admirably adapted for the protection of organs by their solidity, flexibility, and elasticity.

CARTOUCHE, Louis Dominique, a French robber, born in Paris about 1693, executed Nov. 28, 1721. He organized a band of desperadoes, whose robberies and murders spread terror among the Parisians. For years, notwithstanding a high price had been put on his head, he baffled the police, and was arrested by mere chance in a cabaret. His trial, which lasted for several months, created a deep sensation; and an immense crowd gathered to witness his execution. He was broken on the wheel alive; but to the last moment the public and himself were under the impression that he would be rescued by his companions.

CARTWRIGHT, Edmund, an English clergyman, inventor of the power loom, born at Marnham, Nottinghamshire, April 24, 1743, died Oct. 30, 1823. He was educated at Oxford, was elected a fellow of Magdalen college, and was rector of Brampton, Derbyshire, and afterward of Goadby Marwood, Leicestershire. His early life was passed in lettered ease, and was especially devoted to poetical composition. During the summer of 1784, happening to be at Matlock, he had a conversation with some gentlemen from Manchester on the subject of mechanical weaving. He had never till now, in his 40th year, taken any interest in mechanics, but by April of the succeeding year he had his first power loom in running order. The invention was opposed equally by spinners and their workmen. The latter class saw in it a machine that would deprive them of bread; the other feared it was a device that would diminish their profits. A mob set fire to the first factory and burned it with 500 spindles. Improvements were added to the original machine, and it slowly made its way. For many years, however, Cartwright derived no pecuniary benefit from his invention. He patented

several other machines, of which the principal was one for wool combing. Numerous societies awarded him premiums, but he received no substantial benefits from any of his inventions till 1809, when, on the memorial of the principal cotton spinners, parliament voted him £10,000. This sum placed him in easy circumstances, and he devoted his time to experiments in the adaptation of steam power to boats and carriages, but died without attaining any important result.

CARTWRIGHT, John, an English political reformer, elder brother of the preceding, born at Marnham in 1740, died Sept. 23, 1824. At the age of 18 he entered the navy, but at 35 was still a lieutenant. Meantime the struggle between Britain and her colonies enlisted his sympathies for the Americans. In 1774 he published his "Letters on American Independence," and at the same time requested to be placed on the retired list, rather than fight against the colonists. Lord Howe vainly attempted to shake his resolution in this respect. Having retired to Nottinghamshire, where he possessed some property, he received a commission as major in the militia. His appointment gave great offence to the government, who signified their disapprobation so pointedly to the lord lieutenant that he refused Cartwright the usual step of promotion to the lieutenant-colonelcy, although five successive vacancies occurred in that office. He retired from the regiment in 1792, and about this time removed to Lincolnshire. His name now becomes prominent in the history of parliamentary reform. He contended for annual parliaments and universal suffrage. These he supported with voice and pen, in coöperation with Dr. Jebb, Granville Sharpe, Horne Tooke, Hardy, Thelwall, Cobbett, Hunt, and other liberals of the day. Mainly through his instrumentality the citizens of Birmingham were induced to elect a delegate claiming a seat in parliament under the name of their legislative attorney, although that city, the third in the kingdom, had no representation in that body. For his share in this proceeding Cartwright was tried in 1820 on a charge of sedition, and fined £100. Again, when procuring signatures in Huddersfield to a mammoth petition, he was arrested on a charge of exciting a riot, but released. The English liberals placed much reliance in the integrity of his purposes. Sir William Jones declared that his declaration of the people's rights should be written in letters of gold. Fox, in his place in parliament, said that few men united so complete a knowledge of the people's constitutional rights with such high intelligence and such conscientious views. His views on the American revolution were summed up in this sentence: "The liberty of man is not derived from charters but from God, and is original in every man." He was one of the earliest who maintained that the slave trade was piracy. In 1831 a bronze statue of him was erected in

Burton crescent, London. His life was published by his niece (2 vols. 8vo, London, 1826).

CARTWRIGHT, Peter, an American clergyman, born in Amherst co., Va., Sept. 1, 1785, died near Pleasant Plains, Sangamon co., Ill., Sept. 25, 1872. His parents removed in his childhood to Kentucky, where about 1801 his religious zeal was aroused by an itinerant preacher, and he joined the Methodist Episcopal church. He was ordained as deacon in 1806, and as elder in 1808, and preached for many years to the backwoodsmen, upon whom his homely but forcible and earnest utterances produced a deep impression. In 1812 he was appointed a presiding elder, spent eight years in the old Wesleyan conference, four in the Kentucky, eight in the Tennessee, and over 45 years in the Illinois conference. He was a member of every quadrennial conference from 1816 to 1860, and again in 1868. He travelled 11 circuits and 12 presiding elders' districts; received more than 10,000 members into the church, baptized more than 12,000 persons, pronounced on an average four discourses a week for 33 years, and preached in all about 15,000 sermons. His "Fifty Years a Presiding Elder," and the "Autobiography of Peter Cartwright, the Backwoods Preacher," edited by the Rev. W. P. Strickland (New York, 1856), furnish vivid pictures of the life of a frontier preacher.

CARTWRIGHT, Thomas, an English Puritan divine, born in Hertfordshire about 1535, died Dec. 27, 1603. He studied divinity at St. John's college, Cambridge; but afterward he turned his attention to the legal profession, and became clerk to a counsellor at law. Eventually, however, he returned to the university, and was chosen fellow of St. John's in 1560. He was appointed Lady Margaret's reader of divinity in 1570, and provoked the hostility of Sir William Cecil and Dr. Whitgift by the constancy with which he advocated the Puritan doctrines and discipline. In 1571, when the latter became vice chancellor of the university, he was deprived of his professorship, and in the following year of his fellowship. He then repaired to the continent, and was chosen minister to the English merchants at Antwerp and Middelburg. At the end of two years he returned to England, and published a second admonition to parliament in behalf of the Puritans. A protracted controversy with Whitgift, afterward archbishop of Canterbury, was the result of his publication, and Cartwright had again to expatriate himself, officiating while abroad as minister to English communities. In 1580 James VI. of Scotland offered him a professorship in the university of St. Andrews, which he declined. He was imprisoned on his return in 1582, but was released through the influence of Burleigh and Leicester, the latter making him master of the hospital which he had founded at Warwick. He was again committed to prison in 1585 and 1591, and in 1592 was reinstated in his mastership of the Warwick hospital, and was

again permitted to preach. His "Confutation of the Rhemish Translation, Glosses, and Annotations on the New Testament" was published after his death, in 1618. He was also the author of several commentaries on the Bible and of other works.

CARÚPANO, a maritime town of Venezuela, in the state of Cumaná, 260 m. E. of Carácas; lat. 10° 40' N., lon. 63° 22' W.; pop. of the town and canton about 10,000. It is charmingly situated near the base of high hills commanding an extensive view of the surrounding country, much of which is covered with forests and marshes. There are a church, a grammar and a primary school, and some parochial charitable institutions. The climate is hot, and generally insalubrious owing to the prevailing moisture and the exhalations from the marshes. The principal employments of the inhabitants are agriculture and the raising of horses and mules, numbers of which are exported, as are also fruits and other tropical productions. The port is commodious, and is defended by a battery situated on an eminence.

CARUS, Karl Gustav, a German physician and naturalist, born in Leipsic, Jan. 3, 1789, died in Dresden, July 28, 1869. After studying in the gymnasium and university of his native place, he devoted himself to chemistry, in order to aid his father, who was a dyer. He soon left chemistry, and in 1811 graduated at Leipsic as a physician. Engaged as teacher in the university, he was the first to deliver there a distinct course of lectures on comparative anatomy. In 1813 he was appointed to the French hospital at Pfaffendorf, near Leipsic, and by his devotion to his patients contracted a severe illness. The following year, on the reorganization of the medico-chirurgical academy of Dresden, he was appointed professor of midwifery, and at the same time had the clinical direction of the lying-in hospital. In 1827 he resigned his professorship on being appointed physician to the king of Saxony. He continued, however, to lecture, and in 1827 delivered a course of lectures on anthropology, and in 1829 on psychology, which added greatly to his previous reputation. Besides his professional and scientific labors, Carus was a painter of marked talent. His reputation rests mainly on his discovery of the circulation of the blood in insects, for which he received a prize from the French academy of sciences, and his contributions to the history of development in animals. His principal works are: *Versuch einer Darstellung des Nervensystems, und insbesondere des Gehirns* (Leipsic, 1814); *Lehrbuch der Zootomie*, with 20 plates engraved by himself (1818); *Erläuterungstafeln zur vergleichenden Anatomie* (3 vols., 1826-'35); *Ueber den Blutkreislauf der Insecten* (1827); *Grundzüge der vergleichenden Anatomie und Physiologie* (3 vols., Dresden, 1828); *Vorlesungen über Psychologie* (Leipsic, 1831); *Briefe über Landschaftsmalerei* (1831); *Symbolik der menschlichen Gestalt* (1852); *Erfahrungsergebnisse aus*

ärztlichen Studien und ärztlichem Wirken während eines halben Jahrhunderts (1859); *Natur und Idee, oder das werdende und sein Gesetz* (Vienna, 1861); and *Lebenserinnerungen und Denkwürdigkeiten* (4 vols., Leipsic, 1865-'6).

CARUS, Marcus Aurelius, a Roman emperor, born at Narbo (Narbonne) in Gaul (according to other authorities, at Milan or in Illyria), about A. D. 222, died in 283. His descent is doubtful, but it is supposed that his father was an African, and his mother a noble Roman lady. He was educated in Rome, attained the highest military and civil offices, was praetorian prefect, and was proclaimed emperor by the legions, on the assassination of Probus, in 282. He caused justice to be executed upon the assassins. He gained a signal victory over the Sarmatians, and prosecuted the war against the Persians. Undertaking the campaign in midwinter, and making a rapid march through Thrace and Asia Minor, he ravaged Mesopotamia, made himself master of Seleucia, and carried his arms beyond the Tigris, where he died suddenly in his camp, according to some killed by a stroke of lightning.

CARUS, Victor Julius, a German zoologist, born in Leipsic, Aug. 25, 1823. He is the grandson of Friedrich August Carus (1770-1807), who was a professor and author of six posthumous volumes on philosophy (1808-'10). His father, Ernst August Carus (1795-1854), was for many years professor of surgery at Dorpat, and author of a handbook of surgery (1838). Victor was educated at the university of Leipsic, became assistant physician there, and in 1849 was appointed director of the museum of comparative anatomy at Oxford. He returned to Leipsic in 1851, and has been since 1853 professor of comparative anatomy and director of the zoötomical collection in that university. He has published *System der thierischen Morphologie* (1853); *Icones Zootomicae* (1857 *et seq.*); with Engelmann, *Bibliotheca Zoologica* (2 vols., 1862); with Gerstäcker, *Handbuch der Zoologie* (1868 *et seq.*); and *Geschichte der Zoologie bis auf Johannes Müller und Charles Darwin* (Munich, 1872).

CARVAJAL, Tomas José Gonzales, a Spanish author, born in Seville, Dec. 21, 1753, died Nov. 9, 1834. He was appointed in 1795 governor of the new colonies in Sierra Morena and Andalusia; protested against the French invasion of Spain in 1808; from 1809 to 1811 served as commissary in the Spanish army against Napoleon; in 1813 became minister of finance; relinquished these offices to assume the directorship of the royal university of Isidro; was arrested and detained in prison from 1815 to 1820, and exiled from 1823 to 1827. At the time of his death he was member of the supreme council of war, of the military department of the Spanish and Indian boards, and a grandee of Spain. He learned Hebrew at the age of 57, in order to translate the Psalms. He published *Los Salmos* (5 vols., Valencia, 1819), and *Los libros poeticos de la Santa Bi-*

bliä (6 vols., Valencia, 1827). His *Opusculos ineditos en prosa y en verso* appeared after his death (13 vols., Madrid, 1847).

CARVALHO E MELLO. See **POMBAL**.

CARVER, a S. E. county of Minnesota, bounded S. E. by the Minnesota river, and intersected by Crow river; area, 375 sq. m.; pop. in 1870, 11,586. The surface is undulating, the soil fertile, and it is watered by numerous lakes and streams. There is a railroad from Minneapolis to Chaska, and the proposed Hastings and Dakota railroad will pass through it. The chief productions in 1870 were 298,852 bushels of wheat, 122,140 of Indian corn, 140,375 of oats, 33,987 of barley, 54,207 of potatoes, 19,694 tons of hay, 211,497 lbs. of butter, and 16,313 of wool. There were 1,691 horses, 4,170 milch cows, 8,381 other cattle, 5,501 sheep, and 7,874 swine. Capital, Chaska.

CARVER, John, first governor of Plymouth colony, born in England, died at Plymouth, Mass., in April, 1621. He left his country for the sake of religion, and established himself at Leyden, whence he was sent to effect a treaty with the Virginia company concerning territory in North America. He obtained a patent in 1619, and proceeded in the Mayflower with 101 colonists. After a dangerous voyage they arrived at Plymouth, where Carver was unanimously elected governor. He managed the affairs of the infant colony with prudence, and exhibited great address in his intercourse with the Indians, but died within four months after landing, his wife surviving him only six weeks.

CARVER, Jonathan, an American traveller, born at Stillwater, N. Y., in 1732, died in London, Jan. 31, 1780. He abandoned the study of medicine for a military life, bought an ensigncy, became a captain, and served in the war by which the Canadas came into the possession of Great Britain. At the conclusion of peace in 1763 he undertook to explore the interior of North America, and to open new channels of commerce. He penetrated to the Minnesota river, and returned to Boston in 1768. Proceeding to England, he unsuccessfully solicited from the king requital of his expenses, and aid in publishing his charts and journals. He was even commanded to deliver up his papers, now ready for publication, as being the property of the government, and was obliged to repurchase them from the bookseller to whom he had sold them. In 1778 he published "Travels through the Interior Parts of North America," and in 1779 a "Treatise on the Culture of the Tobacco Plant."

CARVIN, a town of France, in the department of Pas-de-Calais, 15 m. N. E. of Arras; pop. in 1866, 6,546. It has starch and sugar factories, and distilleries.

CARY. I. Alice, an American author, born in the Miami valley, 8 m. N. of Cincinnati, Ohio, April 26, 1820, died in New York, Feb. 12, 1871. Her parents were people of considerable culture, but she had only the slight advantages of education afforded by a newly settled country.

She began writing verses at the age of 18 years, and for the next ten years made frequent contributions in prose and verse to newspapers and magazines. She first attracted attention by some sketches of rural life published in the "National Era," under the signature "Patty Lee." The "Poems of Alice and Phœbe Cary," of which about one third were written by the latter, appeared in Philadelphia in 1849. In 1850 the two sisters removed to New York, where they devoted themselves with industry and success to literary labor. Alice became a constant contributor to the leading literary periodicals of the country, and her articles, both prose and poetry, were subsequently collected in volumes which were warmly welcomed both at home and abroad. She also wrote novels and poems which made their first appearance in book form. Her poems are characterized by a rare naturalness and grace, while her prose is remarkable for its realistic character and charming descriptions of domestic life. Her last illness was protracted and attended with much suffering, but was borne with patience and cheerfulness. Alice Cary's published works, besides the volume above mentioned, are: "Clovernook Papers," in two series (1851 and 1853), and "The Clovernook Children" (1854), containing sketches of western life and scenery; "Hagar, a Story of Today" (1852); "Lyra and other Poems" (1853; enlarged ed., including "The Maiden of Tlascalala," 1855); "Married, not Mated" (1856); "Pictures of Country Life" (1859); "Lyrics and Hymns" (1866); "The Bishop's Son" (1867); "The Lover's Diary" (1867); and "Snow Berries, a Book for Young Folks" (1869). **II. Phœbe**, an American poetess, sister of the preceding, born near Cincinnati, Sept. 4, 1824, died at Newport, R. I., July 31, 1871. She contributed frequently to periodicals, but her writings were chiefly poems very different in style from those of her sister, being more buoyant in tone and more independent in manner. One of her earliest poems, "Near Home," written in 1842, attracted very general attention. Her household duties while living in New York with her sister interfered somewhat with her literary labor. Her published works, besides the contributions to the volume issued in conjunction with her sister, were: "Poems and Parodies" (1854); "Poems of Faith, Hope, and Love" (1868); and a large portion of the "Hymns for all Christians," compiled by the Rev. Dr. Deems in 1869. She wrote a very beautiful and touching tribute to her sister's memory, which was published in the "Lady's Repository" a few days before her own death.—See "Memorial of Alice and Phœbe Cary, with some of their Later Poems," by Mary Clemmer Ames (New York, 1873).

CARY, Archibald, an American patriot, born in Virginia about 1730, died there in September, 1786. His family was descended from Henry Lord Hunsdon, and at the time of his death he was the heir apparent of the barony. He

early became a member of the house of burgesses. In 1764 he served on the committee which reported the address to the king, lords, and commons, on the principles of taxation; and in 1770 was one of the signers of the "mercantile association," pledged to use no British fabrics thereafter, the design being to resist by practical measures the encroachments of the government. In 1773 he was one of the committee of correspondence by which the colonies were united against parliament; in the following year he was a member of the convention which appointed delegates to the general congress; and he served with great distinction in the convention of 1776. As chairman of the committee of the whole he reported the resolutions instructing the Virginia delegates in congress to propose independence. When the state government was organized he was returned to the senate, of which he was chosen president. At this time occurred the incident with which his name is most generally connected. The scheme of a dictatorship had been broached, and without his knowledge or consent Patrick Henry was spoken of for the post. In the midst of the general agitation Cary met Mr. Syme, Mr. Henry's half-brother, in the lobby of the assembly, and said to him: "Sir, I am told that your brother wishes to be dictator. Tell him from me that the day of his appointment shall be the day of his death, for he shall find my dagger in his heart before the sunset of that day." The project was speedily abandoned. Cary soon afterward retired to his estate of Amptill, in Chesterfield co., where he died. He was a good representative of the former race of Virginia planters, delighting in agricultural pursuits, in blooded horses, and improved breeds of cattle. He was a man of singular courage, and was called by his contemporaries "Old Iron."

CARY, Henry Francis, an English clergyman and writer, born in Birmingham, Dec. 6, 1772, died in London, Aug. 14, 1844. He early distinguished himself by an "Ode to Kosciusko" and a volume of odes and sonnets. At Oxford he devoted himself to the study of the modern European languages. In 1797 he was appointed vicar of Bromley Abbot's. His translation into blank verse of the *Divina Commedia* of Dante (1806-'14) gained him great celebrity. He also translated the "Birds" of Aristophanes, and some odes of Pindar. His continuation of Johnson's "Lives of the English Poets" from Johnson to Kirke White, and his "Lives of the early French Poets," are meritorious productions; the latter were published anonymously in the "London Magazine" and in a volume edited by his son, the Rev. Henry Cary, in 1846. From 1826 to 1832 he was assistant librarian of the British museum, and received a government pension of £200. He edited editions of Pope, Cowper, Milton, Thomson, and Young. He was buried in Westminster abbey, and his memoirs, by his son, with his literary journal and letters, were published in 1847.

CARY, Lott, one of the founders of Liberia, born a slave near Richmond, Va., in 1780, died at Monrovia, Africa, Nov. 8, 1828. In his youth he was vicious and profane, but in his 27th year he joined the Baptist church. With the change in his character came the thirst for knowledge. He soon learned to read and write, and after a time he began to preach to his countrymen. He succeeded in raising by extra work \$850, with which he redeemed himself and his two children from slavery. He was then employed in a tobacco warehouse with a good salary. In 1815 he became interested in Africa and in the establishment of missions there. In February, 1821, he went to Liberia, and was instrumental in the removal of the colonists from their first unhealthy position to Cape Mesurado, now Monrovia. He exerted himself in the erection of cabins for the settlers, felling trees, prescribing for the sick, preaching, or fighting against the savages, who had determined to exterminate the colonists. Once, when the latter had become dissatisfied with the course of the colonization society in regard to the tenure of their lands, he took sides with them against the agent, Jehudi Ashmun, although personally his friend; but foreseeing the evils which would follow insubordination, he acknowledged his error and submitted to the laws of the society. In September, 1826, Mr. Ashmun sailed for America, leaving the entire control of the colony in the hands of Mr. Cary. He was killed by the explosion of a cask of powder in a building where he was making preparations to repel an assault of the natives.

CARYATIDES, in architecture, female figures which support a roof in lieu of columns or pilasters. Vitruvius says that the inhabitants of Caryæ, an Arcadian village, joined the Persians after the battle of Thermopylæ; after the defeat of the Persians the confederate Greeks destroyed Caryæ, put the male inhabitants to death, and enslaved the women. Sculptors, in commemoration of their infamy, made use of representations of these women to sustain roofs and heavy superincumbent weights; but the use of caryatides is more ancient than the date of the story, and the Greeks probably derived this form in architecture from Egypt.

CASA, Giovanni della, an Italian prelate and author, born near Florence, June 28, 1503, died in Rome, Nov. 14, 1556. He was of a distinguished family, studied in Bologna and Padua, and led a gay life in Rome; but becoming a priest in 1538, he was employed in 1541 on a papal mission to Florence, and elected to the newly founded *accademia fiorentina*. In 1544 he became archbishop of Benevento, and was subsequently nuncio at Venice until after the death of Pope Paul III. (November, 1549). The new pope, Julius III., being unfriendly to him, sold the post of clerk of the camera, which

he had held for seven years. He returned to Venice, remaining there till after the accession of Paul IV. (1555), when his hopes of becoming a cardinal were frustrated partly by his promotion being urged by France, and probably still more by the existence of his licentious poem *Capitoli del forno*. He did not long survive this disappointment. In point of style he was the best Italian prose writer of his day. His most celebrated work, *Galateo*, briefly laying down the rules of polite behavior and illustrating the manners of society, has been translated into foreign languages and passed through many additions. His writings in Latin include translations from Plato and Aristotle. His lyrical poems, edited by Ménage (Paris, 1667), are noted for their purity and delicacy. His licentious poem *Capitoli* (Venice, 1538-'64), has been expunged from the several editions of his complete works (3 vols., Florence, 1752; 4 vols., Milan, 1806).

CASABIANCA, Louis, a French naval officer, born at Bastia about 1755, died Aug. 1, 1798. He entered the naval service when very young, and having adopted the principles of the French revolution, he was elected to the national convention; on the trial of Louis XVI. he did not vote for death, but merely for imprisonment. He subsequently became a member of the council of 500; after which he was appointed captain of L'Orient, the flag ship of Admiral Brueys, the commander of the fleet which took Bonaparte and his army to Egypt. When this fleet was attacked by the English in the bay of Aboukir, Casabianca fought bravely to the last, and was killed with his son, then 10 years old, by the explosion of his ship.

CASACALENDA, a town of S. Italy, in the province and 18 m. N. E. of Campobasso; pop. about 6,000. It contains several churches, one of which is noted for its Tuscan architecture, and a convent. Wine and excellent fruit are largely produced in the surrounding country, and silkworms are reared. Some authorities identify its site with that of the ancient Calela, in the territory of Larinum, where, according to Polybius, Minucius was encamped at a distance of about 16 stadia from the headquarters of Hannibal at Gerunium.

CASAL, or Casal, Manuel Ayres de, a Portuguese geographer, born in the latter half of the 18th century, died at Lisbon in the second quarter of the present century. Having received an excellent education, he took holy orders, but afterward devoted himself to the exploration of Brazil. He has been styled the father of Brazilian geography, and his principal work, entitled *Corografia Brasílica* (2 vols., Rio de Janeiro, 1817), elicited the admiration of Humboldt and of other competent judges.

CASALE, a city of Italy, capital of a district in the province of Alessandria, on the right bank of the Po, 38 m. E. N. E. of Turin, near the site of the ancient Sedula; pop. in 1871, 25,714. The citadel, founded in 1590, was one of the strongest in Italy; and after the cam-

paign against Austria in 1849 the defences, which had fallen into decay, were rebuilt and enlarged. It was the capital of the ancient marquisate of Montferrat, and has sustained several sieges, and frequently changed its masters. It is the seat of a bishop and of a district court of justice, and has a cathedral, founded in 742, a theatre, and a royal college. The church of San Domenico, containing a tomb in memory of the princes Paleologi, is remarkable for the elegance of its design, and several fine works of art are found in other churches. Among the prominent articles of trade are silk, hemp, fruit, and wine.

CASAL-MAGGIORE, a town of Italy, on the Po, in the province and 22 m. S. E. of Cremona; pop. about 4,500. Tanneries, and the manufacture of glass, pottery, and cream of tartar, are carried on. The town has a superior school, a hospital, orphan asylum, and theatre. A victory was achieved here by Sforza over the Venetians in 1448.

CASAL-PUSTERLENGO, a town of Italy, in the province and 30 m. S. E. of Milan, on the Brembiolo; pop. about 5,500. It is the seat of several public offices, has a church and sanctuary, manufactures of silk, linen, and earthenware, and an extensive trade in cheese.

CASAMANZA, a river of Senegambia, rises in the mountains S. of Barraconda, and after a course of 200 m. falls into the Atlantic, about 56 m. S. of the Gambia. Its lower course has been since 1860 within French territory. The French fort of Carabane is situated at its mouth.

CASANOVA, *Giovanni Giacomo de Seingalt*, an Italian adventurer, born in Venice, April 2, 1725, died in Austria about 1803. His father, who was of noble descent, was an adventurer and comedian, and married the daughter of a Venetian shoemaker. Giovanni was sent to Padua, and placed under the instruction of Gozzi; but having been implicated in a brawl between the students and the police, he was forced to leave Padua, and went to Venice. His adventures there are described in his memoirs, and reveal the frivolous character of the Venetian society of those days. Having become notorious for his profligacy, he was finally thrown into the dungeon of San Andrea, but effected his escape, and, after wandering over various towns of Italy, succeeded in finding at Morterano a prelate to whom he brought letters of introduction which his mother had obtained for him, and who recommended him to his friends at Naples. They in turn supplied him with letters to Cardinal Acquaviva in Rome, who brought him into personal contact with Pope Benedict XIV., and this circle of acquaintance laid the foundation for his subsequent career. His devotion to the poetical Marchesa Gabrielli, his mental encounters with the literati, his conversational triumphs in the high social circles of Rome, were all brought to a sudden close by his connivance in an elopement which gave offence to the marchesa, who requested Cardinal Acquaviva to dismiss Casanova, whom

he employed as secretary. The cardinal gave him a passport for Venice, and he eventually reached Constantinople, in company with the Venetian ambassador, into whose favor he had insinuated himself. He was received with great distinction by Cardinal Acquaviva's friend, the pasha of Caramania, alias count de Bonneval, who introduced him to Yusuf Ali, whose wife fell in love with him, while his daughter Zelmi was offered to him in marriage. He left Constantinople surfeited with presents and money, which he lost in gambling soon after his arrival at Venice in 1745, where he accepted a humble musical employment in the orchestra of the theatre San Samuele, in order to save himself from starvation. Here he fell in with the rich Venetian senator Bragadio, but was soon again compelled to remove to other places in order to escape the hands of justice. After figuring as a magician at Cesena, as a priest at Milan, and in various characters at Mantua, Ferrara, Bologna, Parma, and Venice, he made his first appearance in Paris on June 1, 1750. There his reputation had preceded him, and he was received with great favor; the marshal de Richelieu became his bosom friend; the duchess de Chartres doted upon him. After two years in Paris he joined his mother, who was then performing at the theatre of Dresden, and subsequently proceeded to Vienna, where he was received with much favor. On his return to Venice, July 25, 1755, he was lodged in the dungeons of the council of ten. He gives in his memoirs an entertaining but improbable account of the skill and audacity which he displayed in again effecting his escape. Early in 1757 he reappeared in Paris, where the dungeon episode added considerably to his notoriety. He now tried his hand at politics and financiering, and proposed a lottery in order to restore the equilibrium of the French exchequer. A meeting was convened to deliberate on the subject, and D'Alembert in his capacity of mathematician was invited to attend it. Casanova's persuasive power convinced the most skeptical minds of the infallibility of his project; it was actually adopted, but he did not remain to observe its development, being sent as a kind of government spy to Dunkirk. On his return to Paris he met the famous adventurer, the count de St. Germain, whom he subsequently found installed at the Hague. After failing in his various industrial speculations at Paris, Casanova went to Holland under the auspices of the duke de Choiseul, to contract a loan for the French government, while St. Germain had received the same mission from the hands of Louis XV. himself. The two adventurers were well matched, but as they found the Dutch unwilling to advance any money, Casanova resumed his travels. At Roche, in Vaud, he paid his respects to Haller, and at Ferney to Voltaire. At London he met the chevalier d'Eon, and was introduced to George III., but, implicated in a

charge of forgery, left the English capital in a hurried manner. At Brunswick the prince of Prussia helped him out of a pecuniary difficulty. His rencontres with St. Germain continued to be frequent and amusing. At Sans Souci he had an audience of Frederick the Great; at St. Petersburg, of Catharine II. Prince Adam Czartoryski introduced him to the king of Poland. He returned to Vienna, but Maria Theresa would not receive him, and he departed for Spain. There his career forms a continued series of scandals and intrigues. In Barcelona he was put in prison, where he beguiled his time by writing *Confutazione della storia del governo veneto d'Amelot de la Housaye* (Amsterdam, 1769). After recovering his liberty, he betook himself in 1768 to Aix, where he met Cagliostro. But Casanova's roving career was now drawing to its close. At a dinner of the Venetian ambassador at Paris he had met Count Waldstein of Bohemia, a good-natured man, and to escape from the dangers of his precarious position, he accepted the office of librarian in the chateau of the Bohemian count, where he spent the remaining years of his life. Casanova wrote a work on Polish history, translated the Iliad into French verse (4 vols. 4to, Venice, 1778), and was the author of an account of his imprisonment, and various other writings, among which is *Icosameron, ou Histoire d'Édouard et d'Élisabeth*; a narrative of 80 years spent among the inhabitants of the interior of the globe (5 vols. 8vo, Prague, 1788-1800). But his literary fame rests upon his *Mémoires de ma vie jusqu'en 1797*, written during his residence in Bohemia (corrected ed., 8 vols. 8vo, Paris, 1830).

CASAS, Las. See LAS CASAS.

CASA SANTA. See LORETO.

CASAS GRANDES (Span., great houses), a town of about 4,000 inhabitants in Chihuahua, Mexico, on the Casas Grandes or San Miguel river, 35 m. S. of Llanos, which first became noted for ruined edifices, apparently relics of an aboriginal race. These ruins are found about half a mile from the modern town, partly on the declivity of a small hill, and partly on the plain at its foot. They consist chiefly of the remains of a large edifice, built entirely of adobe, or mud mixed with gravel, and formed into blocks 22 in. thick and about 3 ft. long. No stone appears to have been used in them, although the similar structures found in Arizona are entirely built of stone. The outer walls are almost all prostrate, except at the corners, and were probably only one story high; the inner walls are much better preserved, varying in height from 5 to 50 ft., and being in some cases 5 ft. in thickness at the base. The central parts of these, like the exterior walls, have generally fallen, leaving the corners towering above the rest. The portions remaining erect seem to indicate an original height of from three to six stories, but they are so much washed away that it is impossible to discover where the beams were inserted. The door-

ways have the tapering form noticed in the ancient structures of Central America and Yucatan, and over them are circular openings in the partition walls. The stairways in Chihuahua were of wood, but in Arizona of stone. Clavigero, in his "History of Mexico," tells us that the building at Casas Grandes was erected by the Mexicans in their peregrination, and that it consisted "of three floors, with a terrace above them, and without any entrance to the lower floor. The door for entrance to the building is on the second floor, so that a scaling ladder is necessary." It is difficult to form a correct idea of the arrangement of such an edifice, but its main features seem to have been three large structures connected by ranges of corridors or low apartments, and enclosing several courtyards of various dimensions. The extent from N. to S. must have been 800 ft., and from E. to W. about 250 ft. A range of narrow rooms, lighted by circular

House at Tewah, Arizona.

openings near the top, and having pens or enclosures 3 or 4 ft. high in one corner, supposed to be granaries, extends along one of the main walls. Many of the apartments are very large, and some of the enclosures are too vast ever to have been covered by a roof. About 200 ft. W. of the main building are three mounds of loose stones, which may have been burial places; and 200 ft. W. of these are the remains of a building, one story high and 150 ft. square, consisting of a number of apartments ranged around a square court. For some distance S. the plain is covered with traces of similar buildings, the nature of which cannot now be determined; and for 20 leagues along the Casas Grandes and Llanos rivers are found artificial mounds from which have been dug up stone axes, corn-grinders, and various articles of pottery, such as pipes, jars, pitchers, &c., of a texture far superior to that made by the Mexicans of the present day, and generally ornamented with angular figures of blue, red,

brown, and black, on a red or white ground. The best specimens command a high price in Chihuahua and neighboring towns.—On the summit of a mountain, about 10 m. from the

Interior View.

Casas Grandes, are the remains of an ancient stone fortress, attributed to the same people who built the Casas Grandes, which was probably intended as a lookout.—On the Salinas and Gila rivers, in the country of the Pimo and Coco-Maricopa Indians, and in Arizona, are ruins of like character and evidently identical origin, to which the same name is usually applied. The Indians call all such ruins “casas de Montezuma.” Of those on the Salinas little remains but shapeless heaps of rubbish, broken pottery, and the traces of several irrigating canals. On the Gila, however, there are three distinct buildings, all enclosed within a space of 150 yards. The largest measures 50 by 40 ft., and at a distance looks not unlike a square castle, with a tower rising from the centre. The southern wall is badly rent and crumbled, but the other three walls are nearly perfect; they are roughly plastered inside with a composition of adobe. The material of which they are constructed is the same as that used in the Casas Grandes of Chihuahua. The walls are perpendicular within, but their exterior face tapers in a curve toward the top. One of them is covered with rude figures. The ends of the beams, which denote by their charred appearance that the building was destroyed by fire, are deeply sunk in the walls, and show three stories now standing. The lower floor is divided into five apartments. There is an entrance on each of the four sides, but there are no windows except on the W. side, and no traces of an interior stairway. The other two buildings are much smaller, and one of them was perhaps merely a watch tower. Both are badly ruined. About 200 yards distant is a circular enclosure, from 80 to 100 yards in circumference, probably intended for cattle. For miles around the plain is strewn with fragments of pottery.—The origin of these ruins is a subject of doubt. They were seen nearly in their present state by the early explorers of the country, and the Indians then assigned them an age of no less than 500 years. Mr. Squier supposes them to have been the work of the aboriginal race of the Moquis.

Late explorations have shown that the whole of the wide region drained by the Gila and Colorado rivers, now for the most part arid and desolate, was once widely if not densely populated. On the cliffs bordering the Colorado, and on the shelves of its rocky banks, in places apparently inaccessible, are remains of considerable edifices. Throughout the country west of the Rio Grande are the outlines of buildings, discernible by the stones that supported adobe walls, which have now been washed away by rains, or have been disintegrated by time. The stone buildings of the existing Pueblo Indians do not, as far as plan is concerned, differ much from those of their ancestors. They are built around courts, and are generally about three stories high; the walls receding by stages, and access being gained only by the use of ladders. When these ladders are drawn in, the various sides present a perpendicular front to an enemy, and the building itself becomes a fortress. These features indicate that before the conquest the quiet, agricultural population of what is gener-

Moqui Town, near Tewah.

ally called New Mexico was subject to raids or incursions from the barbarous hordes roaming to the north and northeast, against whom their *casas* were probably an efficient protection. The strength of the walls of these structures was proved during the Mexican war, when it was found that they were impregnable to field artillery. To gain greater security, the ancients built on the high *mesas*, or terrestrial islands, that abound in the region they occupied (precisely as did the barons of Europe in the middle ages), whose level summits could only be reached by narrow and easily defensible passes, in many cases hewn in the rock. The remains of the buildings that crowned these natural fastnesses are conspicuous and interesting features in the wide region embraced between the Rio Grande on the east, the Gila on the south, and the Colorado on the west.

CASAUBON. I. Isaac, a Swiss theologian and critic, born in Geneva in February, 1559, died in London, July 1, 1614. He was the son of a French Protestant minister, studied at Lau-

sanne, and afterward at Geneva, where he became professor of Greek at the age of 23, holding the position for 14 years. Meanwhile he married the daughter of Henry Stephens, the celebrated French printer and publisher, by whom he had 20 children. In 1596 he became professor of Greek and belles-lettres in the university of Montpellier. Two years afterward, at the solicitation of Henry IV., he went to Paris to take a similar professorship in the university of France; but the jealousy of the Catholic party made the measure impolitic, and Henry finally appointed a Catholic to the chair, and made Casaubon royal librarian. At the conference of Fontainebleau, May 4, 1600, Henry constituted him one of the Protestant judges. The Catholics made strong efforts to win him to their side, and it was given out that he wavered in his faith. Chagrined that his Protestant reputation was thus impaired, Casaubon determined to leave France, and therefore, availing himself of the occasion of Henry's death to get leave of absence from the queen, he accompanied Sir Henry Wotton to England in October, 1610. He was received with distinction, made prebendary of Canterbury, and some say also of Westminster, and received a pension of £200, which he lived three years to enjoy. He was buried in Westminster abbey. He spoke Latin as well as he did his mother tongue, and was the most critical Greek scholar of his age. His works are numerous, mostly philological and critical, many of them being annotated editions of the classics, including Diogenes Laërtius, Aristotle, Theophrastus, and Suetonius. **II. Meric**, an English divine, son of the preceding, born at Geneva, Aug. 14, 1599, died in England, July 14, 1671. He accompanied his father to England, studied at Oxford, was appointed to the cure of Bleaden in 1624, and four years afterward was made prebendary of Canterbury and rector of Ickham. He received the degree of D. D. at Oxford in 1636. Through his attachment to the Stuarts he lost both property and preferments during the protectorate; and Cromwell made frequent efforts to win him over to the cause of the commonwealth. Christina, queen of Sweden, offered him the superintendency of all the Swedish universities, but he persisted in living in retirement in England until the accession of Charles II., when his ecclesiastical preferments were all restored. He published in his lifetime two vindications of his father from the aspersions of his enemies. His theological and critical works are numerous; he edited some of the classics; and his MSS. are preserved in Oxford. He believed in the existence of witches and familiar spirits, a faith which he endeavored to defend in a work entitled "Credulity and Incredulity."

CASBIN, **Kasbin**, **Kazbin**, or **Casveen**, a fortified city of Persia, in the province of Irak-Ajemi, 90 m. N. W. of Teheran, in lat. 36° 12' N., lon. 49° 53' E.; pop. in 1868 estimated at 25,000. It is surrounded by brick walls with towers, and is said to exceed Teheran in extent; but

whatever grandeur it may have once possessed has been destroyed by repeated earthquakes. Whole streets lie in ruins, and most of the ancient buildings have been overthrown. The palace, though much dilapidated, is still occupied by the governor. A mosque with a large dome, bazaars, schools, and baths are the other principal buildings. The chief manufactures are velvets, brocades, a coarse cotton cloth called *kerbas*, carpets, sword blades, and wine. Grapes and nuts are produced abundantly, and of good quality. It is also an entrepot for the silks of Ghilan and Shirvan destined for Bagdad and India, and for rice from the Caspian provinces. The surrounding plain was formerly one of the most productive districts of Persia, its natural fertility being greatly enhanced by a vast system of irrigating canals, most of which are now choked up, except in the immediate vicinity of the city. Casbin was founded about the middle of the 4th century, and under the Suffide dynasty became the capital of the kingdom. The removal of the government to Ispahan checked its prosperity.

CASCA, **Publius Servilius**, one of the conspirators against the life of Julius Cæsar. He had been attached to the Pompeian party, and, like many others of the dictator's slayers, submitted himself to Cæsar after the battle of Pharsalia, and received a free pardon. It is stated by Plutarch, in his life of Cæsar, that when Tullius Cimber, according to the preconceived plan, gave the signal for the assassination by dropping the fold of his toga from his shoulder, Casca struck the dictator on the back of the neck with a short sword, or dagger, but failed to inflict either a deep or deadly wound, being under the influence of agitation, if not of fear, when delivering the blow. Cæsar on feeling the stroke turned round, it is said, abruptly, and caught the assassin by the arm, crying out, in Latin, "What dost thou, villain Casca?" when Casca calling to his brother in Greek, "Help, brother!" the others rallied to his assistance, and completed the bloody deed. Nothing is known of Casca's history after the death of Cæsar.

CASCADE RANGE, a chain of mountains in the W. part of Washington and Oregon, forming a continuation of the coast range of California. It lies about 100 m. from the Pacific, and runs nearly N. and S. Its highest summits are Mt. Ranier, 14,444 ft., and Mt. Baker, 10,760 ft., in Washington. Mts. Pitt, Jefferson, and Hood are notable peaks of this range in Oregon. The name of the chain is derived from the cascades of the Columbia, which are formed where that river breaks through the Cascade range.

CASCARILLA (Span. *cascara*, bark), a medicinal bark, obtained from *croton Eleutheria*, a small tree or shrub which grows wild in the West Indies and Bahama islands, especially on the island of Eleuthera. It has a spicy, bitter taste, and is used as a tonic. When burnt, it emits an odor so agreeable that smokers have

Cascarilla (*Croton Eleutheria*).

sometimes mixed a small quantity of it with their tobacco, but this is very injurious.

CASCO BAY, on the coast of Maine, lying between Cape Elizabeth and Cape Small Point, 20 m. apart. It contains several hundred small islands, some of which are favorite resorts during the summer season.

CASE, in law, a formal statement of facts agreed upon by the parties, or stated by a judge, with a view to obtaining the judgment of the court thereon. Formerly in England cases were sometimes directed by the court of chancery, in suits pending therein, for the judgment of the common law courts, but this practice is now abolished.—Action on the case, or trespass on the case, is a form of personal action, first used in the reign of Edward III., as a remedy for injuries to which the forms then in vogue were not adapted, and receiving its name from the fact that the case of the plaintiff was set forth in the original writ. It is so comprehensive in its scope as to lie wherever a party has sustained a legal injury to person or property, for which no other form of action affords a remedy. This, which may be called a natural species of action, in contradistinction from those which are of a more technical character, is retained in the codes which have recently been adopted in several of the American states, the purpose of which has been to simplify pleadings and proceedings at law.

CASE, William, an American Methodist clergyman, born at Swansea, Mass., Aug. 27, 1780, died at Alnwick mission house, Canada, Oct. 19, 1855. He was received into the New York conference in 1805, and for 18 years was presiding elder in central and western New York and in Canada. In 1828 he was appointed superintendent of Indian schools and missions in Canada, which post he filled till his death, and became known as "the apostle to the Canadian Indians." He was the director of the Methodist ministry in Canada, and thus became powerful in shaping the religious history of that region.

CASEINE. See CHEESE.

CASERTA. **I.** Or *Terra di Lavoro*, a province of Italy, formerly a part of the kingdom of Naples, bounded by the provinces of Rome, Aquila, Campobasso, Benevento, Avellino, and Naples, and the Mediterranean; area, 2,307 sq. m.; pop. in 1872 695,754. It comprises the districts of Caserta, Nola, Sora, Gaeta, and Piedimonte d'Alife. The most important mountains are Mt. Matese in the southeast, the Tifati mountains in the south, and the Masicco in the northwest. The chief rivers are the Garigliano, with its tributary the Liri, and the Volturno. Agriculture is flourishing, and cattle raising is conducted on a large scale. The province has large woods and silk, linen, and tapestry factories. The marshes N. of the Volturno have by drainage been converted into arable land. **II.** The capital of the province, situated in a fertile plain on the railway line from Naples to Capua, 17 m. N. E. of Naples; pop. in 1872, 29,142. It is the seat of a bishop, has a cathedral, a seminary, numerous churches, a convent, a military school, and excellent barracks, and is noted for its magnificent royal palace and aqueduct, both constructed by Vanvitelli for Charles III. The palace contains a chapel and a large theatre, adorned with columns from an ancient temple of Serapis. The gardens are supplied with water from a distance of 27 m. by means of a fine aqueduct. The principal branch of industry is the manufacture of silks.—On the hills behind Caserta is *CASERTA VECCHIA*, surrounded by a wall and towers probably of the 8th century, and containing a splendid cathedral and other churches. It was once a place of great importance, but has been eclipsed since the foundation of Caserta. Both towns were founded by the Lombards.

CASE-HARDENING, a process of hardening the surface of iron by converting it into steel. For this purpose the articles are placed in an iron case, together with animal or vegetable charcoal, and subjected to the process of cementation. The carbon absorbed does not, in the short time allowed for the operation, penetrate beneath the surface. From two to eight hours is the usual time that the articles are exposed to a dull red heat. They are then taken out of the burnt bone dust or other carbonaceous substance, and further hardened by quenching them in oil or cold water. Sometimes they are left to cool in the case, and are afterward tempered. Prussiate of potash has in various ways been found a very useful material for affording its carbon to iron for producing steel. Being a combination of two atoms of carbon and one of nitrogen with one of potash, it offers no solid residue that interferes with the progress of the chemical change, or impairs the quality of the steel. In case-hardening, it is sprinkled or rubbed upon the iron heated to dull red, and this, after being put in the fire for a few minutes, is taken out and tempered in water. The process is a convenient one where small

articles are to be exposed to much wear, these being easily made of soft iron, and then externally hardened. It is also conveniently applied to give a good surface to small articles which are desired to receive the high polish of which steel is susceptible.

CASES, Count de Las. See LAS CASES.

CASE SHOT, or Canister Shot, a missile consisting of a number of wrought-iron balls, packed in a tin canister of a cylindrical shape. The balls for field service are regularly deposited in layers, but for most kinds of siege and naval ordnance they are merely thrown into the case until it is filled, when the lid is soldered on. Between the bottom of the canister and the charge a wooden bottom is inserted. The weights of the balls vary with the different kinds of ordnance, and the regulations of each service. For siege and garrison artillery, the balls are sometimes arranged round a spindle projecting from the wooden bottom, either in a bag in the shape of a grape (whence the name grape shot), or in regular layers with round wooden or iron plates between each layer, the whole covered over with a canvas bag.—The Shrapnell shell, so called from its inventor, Gen. Shrapnell of the British army, is a thin cast-iron shell, from one third to three fourths of an inch thick, with a diaphragm or partition in the middle. The lower compartment is destined to receive a bursting charge; the upper one contains leaden musket balls. A fuse is inserted containing a carefully prepared composition, the accuracy of whose burning off can be depended upon.

A composition is run between the balls, so as to prevent them from shaking. When used in the field, the fuse is cut off to the length required for the distance of the enemy, and inserted into the shell. At 50 to 70 yards from the enemy the fuse is burnt to the bottom, and explodes the shell, scattering the bullets toward the enemy precisely as if common case shot had been fired on the spot where the shell exploded. The precision of the fuses at present attained in several services is very great, and thus this projectile enables the gunner to obtain the exact effect of grape at ranges where formerly round shot only could be used.

CASEY, a central county of Kentucky, traversed by Green river and the Rolling fork of Salt river; area, 350 sq. m.; pop. in 1870, 8,884, of whom 544 were colored. The surface is hilly and broken. The Cincinnati, Lexington, and East Tennessee railroad is to pass through it. The chief productions in 1870

were 16,773 bushels of wheat, 356,850 of Indian corn, 42,747 of oats, 116,841 lbs. of butter, 22,469 of wool, and 145,982 of tobacco. There were 2,780 horses, 1,972 milch cows, 2,954 other cattle, 12,047 sheep, and 19,240 swine. Capital, Liberty.

CASHAN. See KASHAN.

CASHEL (anc. *Carsiol*, the "habitation in the rock"), a town of Ireland, in the county and 12 m. N. E. of Tipperary, and 90 m. S. W. of Dublin; pop. in 1871, 3,976. Part of it is well built, but it has a poverty-stricken appearance, is destitute of manufactures, and has been on the decline for many years. It contains an Anglican parish church, a nunnery, chapels, schools, barracks, a hospital, an infirmary, and court houses. Its most interesting object is the famous "rock of Cashel," which rises abruptly from the plain outside of the city, and is crowned with the finest collection of ruins in Ireland. These consist of a round tower, a

Cashel Cathedral.

splendid Gothic cathedral built about the 12th century, a monastery and a castle of about the same date, and a chapel of hewn stone, with a roof of the same material, built in the Saxon and Norman styles of architecture, and still showing marks of extraordinary beauty. These remains, which are visible at a great distance, are all within an enclosed area. At the foot of the rock are the ruins of Hore abbey and of a Dominican priory. Donald O'Brien, king of Limerick, and his nobles took the oath of allegiance to Henry II. here in 1172. Cashel was the ancient residence of the sovereigns of Munster, and is often dignified by the title of "the city of kings." In the civil wars following the rebellion of 1641, it was taken by Lord Inchiquin, and afterward by Cromwell. It is the seat of a Catholic archbishopric. The former Anglican archbishopric of Cashel has recently been united with the bishopric of Waterford.

CASHEW NUT, the fruit of the *anacardium occidentale*, cultivated in the West Indies and

other tropical countries. The tree, which resembles the walnut tree, is large, with oval, blunt, alternate leaves; the flower is rose-colored and fragrant; the stem furnishes a milky

Cashew Nut.

juice, which when dry becomes black and is used as a varnish. The tree also secretes a gum having the qualities of gum arabic, and known in commerce as codjii gum. In South America, from whence it is imported, book-binders use it as a varnish for their books to protect them from moths and ants. The fruit is a pear-shaped receptacle, having an agreeable acid flavor with some astringency, and at the end the kidney-shaped ash-colored nut. This has a shell of three layers, the outer and inner hard and dry, while the intermediate contains a quantity of black, acrid, caustic oil, strong enough to excoriate the lips of those who crack the nut with their teeth; and in India it is sometimes applied to the floors to drive away ants. To destroy this acrid matter, the nuts are roasted, which renders them when eaten wholesome and agreeable. The roasting is carefully conducted, as the acridity of the fumes is sufficient to produce severe inflammation in the face and hands of the roaster.

CASHMERE, or **Kashmir**, a kingdom in the N. W. part of India, almost enclosed by ranges of the Karakorum and Himalaya, which separate it from Chinese Tartary, Thibet, and the British districts of Lahoul and Spiti and the Punjaub; area estimated at 75,000 sq. m.; pop. at 750,000. It extends from lat. 32° 17' to 36° N., and from lon. 73° 20' to 79° 40' E., and includes the famous vale of Cashmere, the provinces of Jammoo, Balti, Ladakh, Chamba, and some others. —The valley of Cashmere is of irregular oval form, shut in by lofty mountains, the summits of some of which are covered with perpetual snow. It is from 5,500 to 6,000 ft. above the sea, and the alluvial plain which forms its bottom is 70 m. long, 40 m. wide, and about 2,000 sq. m. in area, that of the whole valley being 4,500 sq. m. It is entered by many passes, 11 of which are practicable for horses. The highest, including that of the Pir Panjal, have

an elevation of about 12,000 ft. The principal river is the Jhylum, a tributary of the Indus, which receives numerous tributaries from the mountains, and flows through the Baramula pass into the Punjaub. Several small lakes are scattered through the valley. Thus abundantly irrigated, and fertilized by rains which, unlike those of most parts of India, are light, the soil attains an extraordinary fertility, yielding returns of from 30 to 60 fold of the principal crops. Rice, the common food of the inhabitants, is the staple; wheat, barley, buckwheat, maize, and tobacco are cultivated to some extent; cotton is found to flourish; esculent vegetables, kitchen herbs, and saffron are abundant; and the lakes supply the poorer classes with a nutritious though insipid article of food in the *singhara* or water nut, the seed of the *trapa bispinosa*, which is ground into flour, roasted, boiled, or eaten raw. About 60,000 tons of this nut are annually taken from the Wullur lake. Among the fruits are the apple, pear, peach, plum, apricot, cherry, pomegranate, and grape. Flowers of rare beauty, particularly the rose, which is highly cultivated, abound in the valley. Many of the forest trees attain a vast size; among them are the Himalayan cedar, the chunar, the poplar, the lime, and the wild chestnut. The willow, maple, birch, alder, pine, and white thorn are common. Every village has its grove of chunars and poplars, planted centuries ago by order of the Mogul emperors, and now forming one of the richest ornaments of the valley. Bears, both brown and black, are very numerous. The other wild animals are leopards, jackals, foxes, stags, gazelles, and wild goats. Birds of prey are numerous, including a species of vulture of great size. Game birds are very plentiful. Venomous reptiles are rare. The native horses are small and hardy. Cattle, sheep, and goats are numerous.—The most valuable minerals are iron and limestone, both of which are abundant; copper, plumbago, and lead are also known to exist. The climate is salubrious, and milder than in many parts of India, but the stillness of the midsummer air gives the heat an oppressiveness scarcely to be expected from the range of the thermometer (80° to 85° at noon in the shade), and the winter is sometimes severely cold. Snow falls abundantly. The bulk of the inhabitants are Mohammedans, speaking a Sanskrit dialect, with a large admixture of Persian, in which latter tongue the records and correspondence of the government are written. They are divided in sect into Sunnis and Shiah, the former being the more numerous and regarded as orthodox. The Cashmerians are preëminent among Indian nations by their physical perfections. The men are tall, robust, well formed, and industrious; the women famous for their beauty and fine complexions. They are a gay people, fond of pleasure, literature, and poetry, but are represented by many travellers as peerless in cun-

ning and avarice, and notoriously addicted to lying. They appear to be of Hindoo origin. At the beginning of the present century the population of the valley was 800,000, which

Cashmerian Boatmen.

has been reduced by pestilence, famine, and earthquakes to 200,000. In 1828 an earthquake destroyed 1,200 persons; two months later the cholera carried off 100,000 in 40 days; and in 1833 famine and pestilence committed still more frightful ravages. The chief towns are Serinagur or Cashmere, the capital (see SERINAGUR), Islamabad, Shupeyon, Pampur, and Sopur. The principal manufactures are the celebrated Cashmere shawls, gun and pistol barrels, paper, lacquered ware, and attar of roses.—The country was conquered by the Mogul emperor Akbar in 1587, by the Afghans in 1752, and by the Sikhs in 1819. It was included in the territory transferred by the latter to the British under the treaty of Lahore in 1846, and was immediately sold by its new owners to Gholab Sing for the sum of £750,000; but by the compact between the maharajah and the British government, the rajah is to be assisted in defending himself against his enemies, and British supremacy is acknowledged.—See Vigne's "Travels in Kashmir" (2 vols., London, 1842); "Travels in India and Kashmir," by E. Schönberg (2 vols., London, 1853); and "Diary of a Pedestrian in Cashmere and Thibet," by Captain Knight (London, 1863).

CASHMERE (Fr. *cachemire*), a textile fabric made of the fine wool of the Thibet goat. In Cashmere the wool is received from Thibet and Tartary, and, after being bleached, is spun and dyed of various colors. The weavers, employed by the merchants for a few cents a day, receive the yarns, and in their shops, or at looms in their own houses, proceed to weave them after the patterns ordered. Each loom

is estimated to produce five shawls a year; but a single one of the finest shawls sometimes occupies the work of a whole shop, keeping two to four persons constantly engaged upon it, for an entire year. The total number of looms in Cashmere, it is believed, is about 16,000. The process of weaving the shawls with variegated figures is conducted without a shuttle, each colored yarn of the wool being worked upon the warp with its separate wooden needle; and as the work goes on very slowly, it is customary to divide it among several looms, and then join the pieces together. This is so skilfully done that the seams are not detected. As the pattern is worked, the right side is the under one upon the frame, and is not seen by those who work it upon the upper or rough side. The shawls are made single and in pairs, either square or long; the former measures from 63 to 72 inches on a side, the latter 126 inches by 54. To work a single long shawl without a seam, and of the finest thread in the warp as well as the wool, in the most elaborate pattern and exquisite colors, would require the labor of about three years; and as in this time the colors are likely to change, and the fabric to receive injury from worms or otherwise, such shawls are rarely attempted. The fine shawls are more usually made upon 12 different looms for a pair.—The principal market is in the London semi-annual public sales, which of late years have materially decreased, chiefly owing to the direct importation into France by Paris houses having agents in Cashmere. In 1852 the London sales amounted to £100,000; in 1862, £270,000; in 1869, only £80,000. In 1871 the total import of India shawls into England was 1,557, against 3,343 in 1870. On account of the Franco-German war there was but one public sale in 1871, amounting to £27,000. In 1872 the June sale amounted to £36,245. These sales included long shawls, square with plain and filled centres, pieces, scarfs, cravats, capes, fringes, &c. The buyers are from France, Belgium, Germany, England, the United States, and sometimes from Russia and Turkey. The prices range from £2 to £70, and occasionally £100 for exceptional qualities and patterns. The finest and choicest shawls now go exclusively to Paris direct from India; Russians and Italians sometimes buy the best, but do not import them. Very few of the higher priced shawls are manufactured, though in some public sales in London shawls have been sold at from £160 to £220 each. The maharajah of Cashmere has control of the exports of shawls, and through his agents sends some to the London sales.—Various attempts have been made to naturalize the Thibet goat in Europe and the United States. In 1819 a cross between the Thibet and a Tartar variety was introduced into France, and subsequently some of the stock was sent to England. Some years ago Dr. J. B. Davis of Columbia, S. C., imported nine pure breed Thibet goats, the stock of

which was introduced into Tennessee and other states. But all attempts at naturalization have resulted in the production of an inferior quality of wool, owing, it is supposed, to the influences of climate. In California, however, the goat has been successfully introduced, and is now very numerous; and it is thought that the climate of that state will be favorable to the quality of the wool. The attempts to import and manufacture the wool in Europe have not been successful. The native weavers are brought up to the trade from their infancy, and are proficient in the highest degree; while to the water of India in which the wool and shawls are washed, and to the atmosphere, the brilliant colors of the cashmere shawls are supposed to be due. In Paris, Lyons, Nimes, and Rheims there are extensive manufactories for the production of imitation cashmere shawls, the best of which are easily distinguished from the genuine ones by experts, but which are extensively exported. The value of India shawls imported into New York in 1872 was \$164,118.

CASIMIR (Pol. *Kazimierz*), the name of several monarchs of Poland. **I. The Peaceful**, son of Miecislus II. and of Rixa, a German princess, died in 1058. After the death of his father in 1034 his mother ruled the country as regent; but the favors she bestowed upon her own countrymen, and their ill conduct, caused an outbreak of national hatred, and Rixa fled to Germany. Casimir followed her. Poland, left without a ruler, became a scene of the wildest anarchy and lawlessness; the lately established Christian church also suffered greatly from pagan persecutions. Profiting by this state of affairs, the Bohemians made an incursion into Poland, and advanced as far as Gnesen. In 1040 Casimir was recalled by his countrymen from Germany, where he was living in quiet retirement occupied with exercises of religious piety, which gained him the surname of "the Monk." Slightly assisted by Henry III. of Germany, he regained his authority, and restored Christianity and a regular administration of justice, conquered Masovia, gained Breslau and other places from the Bohemians, and was honored with the title of restorer of Poland. His wife was Dobrogniewa, sister of Yaroslav, the grand duke of Kiev. His successor was Boleslas II. the Bold, his eldest son. **II. The Just**, born in 1138, died in 1194. He was the youngest of the four sons of Boleslas III., among whom that monarch divided Poland, and reigned over the reunited country after the expulsion of Miecislus III. in 1177. He is greatly renowned for his personal virtues, as well as for the introduction of laws defending the peasants against the nobles and officers of the court. Under him the Polish senate was first organized, consisting of bishops, palatines, and castellans. He made successful expeditions to Volhynia, Halicz, and Lithuania. **III. The Great**, born in 1309, died Nov. 5, 1370. He was the son and successor of Ladislas Lo-

kietek (the Short), who had restored the union and the power of the long distracted kingdom. While still a prince Casimir displayed his talents as governor of Great Poland, as well as his bravery in the wars of his father against the order of Teutonic knights, but also exhibited habits of great dissoluteness. In 1333 his father bequeathed him his throne, with the advice not to enter into any treaty with the Teutonic knights; but the inclinations of the young king were for peace, and he soon concluded a treaty, in which the knights ceded the districts of Kujaw and Dobrzyn, but gained Pomerania. To secure peace from the kings of Bohemia, he sacrificed to them the rich province of Silesia for the resignation of their claims on Poland. The Polish nation, dissatisfied with his acts, sought redress at the court of Rome. The pope gave a favorable decision, commanding the knights to restore all the Polish districts, and to rebuild the destroyed churches; but the knights scorned the bull, and maintained their conquest. In the mean while Casimir had strengthened his reign by salutary and peaceful reforms, as well as by the erection of numerous castles and fortifications. The adoption of his nephew, Louis, son of Charles Robert, king of Hungary, as successor to the throne of Poland, confirmed by the assembly of the nation at Cracow (1339), secured the alliance with Hungary. In 1340 the death of Boleslas of Masovia and Halicz, who died without progeny, offered a favorable opportunity for the annexation of Red Russia, which was easily executed in two successful campaigns. A consequence of these was an incursion of the Tartars (1341), at the summons of certain Russian princes, who pretended to have been wronged. Casimir fortified and defended the line of the Vistula, and by the speedy retreat of the invaders Poland escaped total destruction. In 1344 some difficulties, caused by the dukes of Silesia, brought about a short war with the king of Bohemia, which was begun by the conquest of Silesia, and ended with the acquisition only of Fraustadt. Subsequently parts of Lithuania, Masovia, and Volhynia were added to Poland. But the successes achieved by Casimir in time of peace were still more glorious. The diet of Wislica (1347) sanctioned a double code of laws for Great and Little Poland, digested by the ablest men of the country, based in part on the ancient statutes of the nation, and in part on the German or the so-called Magdeburgian institutions, according to which the commercial cities were governed. The rights of both nobles and peasants were determined and secured, and so great was the zeal of Casimir in defence of the latter against the former, that he was called the king of the peasants (*król kmiotków*). No less great was his ardor and activity in promoting industry, commerce, arts, and sciences (particularly proved by the foundation in 1364 of the university of Cracow), and in adorning and strengthening the country with buildings

for public use and defence; and thus he deserved the remark of an ancient historian, that he inherited Poland of wood and left it of stone. Agriculture, industry, and general wealth gradually increased under Casimir; and the riches and liberality of the state were displayed on the occasion of the marriage of his granddaughter with Charles IV., emperor of Germany, which was celebrated for 20 days at Cracow. But his reign had also its shades: unhappy marriages; love affairs condemned by the people and the church; an excommunication by the archbishop of Cracow; a deadly revenge taken on its innocent announcer; the subsequent humiliation of the king by the pope; and a great defeat by the Wallachians. A fall from a horse ended the life of the most popular monarch of Poland.—Among the objects of the love of Casimir was the Jewess Esther, the heroine of many romances, by whom he had several children, and who is supposed to have contributed greatly to the humane protection which he and his laws bestowed on her people in Poland, in the time of most barbarous persecutions in other parts of Europe. **IV.** Born in 1427, died at Grodno in 1492. He was the son of Ladislas Jagiello, and brother and successor of Ladislas III., at whose death in 1444 Casimir was grand duke of Lithuania. He accepted, but hesitatingly, the call to the throne of Poland. His long reign is remarkable for several diets held at Lublin, Piotrków, &c.; for a successful war of 14 years against the Teutonic knights, terminated in 1466 by the peace of Thorn, which gave to Poland the western part of Prussia and the suzerainty of the eastern; and for the subsequent long period of general prosperity, luxury, and relaxation of the national spirit. The introduction of the Latin language into the schools and public life of Poland dates particularly from this reign. Of the six sons of Casimir, one was elected king of Bohemia and Hungary, three, John Albert, Alexander, and Sigismund, succeeded each other on the throne of Poland, one became a cardinal, and one was canonized. **V.** See JOHN CASIMIR.

CASINO, or *Monte Casino*, a celebrated Benedictine monastery, established by St. Benedict in 529, upon the mountain of the same name, in the Italian province of Caserta, over the town of San Germano, the ancient Casinum, 48 m. N. N. W. of Naples, in former times the seat of a famous castle, and of a temple of Apollo. The beauty of the spot attracted many visitors to the abbey, and the medical skill of the friars many invalids, while pilgrims resorted there from all parts of the world, as the Benedictines were deemed to possess miraculous balms derived from Mount Zion. The monastery is a massive pile, more like a palace than a convent. The church, erected by St. Benedict, was destroyed in the 6th century by the Lombards, rebuilt in the 8th, destroyed by the Saracens in the 9th, restored at the beginning of the 10th, ravaged by the Normans

and rebuilt in the 11th; ruined by an earthquake in 1349, and restored in 1365; fell down in 1649, and was rebuilt as it now stands, and consecrated by Pope Benedict XIII. in 1727. Its interior surpasses in beauty and costliness of decoration every church in Italy except St. Peter's. In our times the abbey presents many intellectual attractions, as its inmates have established a press and published a variety of valuable works.

CASORIA, a town of Italy, 5 m. N. E. of Naples; pop. about 7,000. It is the birthplace of the painter Pietro Martino. It has four churches, and produces quantities of silk.

CASPARI, *Carl Paul*, a German theologian, born at Dessau, Feb. 8, 1814. He studied in Leipsic and Berlin, and in 1857 became professor of divinity at the university of Christiania in Norway. He has written a number of critical works on Biblical subjects, including treatises on Obadiah, Isaiah, Micah, Daniel, and the apostolic symbols, and has been active as joint editor of the Lutheran *Tidskrift* of Copenhagen. A third edition of his *Grammatica Arabica* appeared in 1866.

CASPE, a town of Spain, in the province and 50 m. S. E. of Saragossa, near the confluence of the Guadalupe with the Ebro; pop. in 1867, 9,402. It has a castle, several convents, and four hospitals. In the neighborhood are extensive plantations of olive and mulberry trees. In 1412 a congress was held here of the Aragonians, Catalonians, and Valencians, to settle the succession to the throne.

CASPIAN SEA (called by the Russians also the sea of Astrakhan; anc. *Mare Caspium* or *Hyr-canium*; Gr. *Καρία θάλασσα*), an inland sea, lying between Europe and Asia, between lat. 36° 30' and 47° 30' N., and lon. 46° 48' and 54° 25' E.; greatest length from N. to S., 760 m.; greatest breadth, 300 m.; average breadth about 200 m.; area, according to Berghaus, 156,800 sq. m. It is bounded N. W., N., and N. E. by Russia, S. and S. W. by Persia, and E. by Turkistan. It has few bays, the most important being, on the Asiatic side, Emba bay, Mertvoi gulf, Karasu inlet, Manghishlak gulf, bay of Alexander, Kenderlinsk gulf, Kara-Bugaz bay, and Balkan bay; on the European side, Kizil Agatch and Kuma gulfs, and several smaller indentations. At the S. extremity of the sea is Astrabad bay. The Emba river, which enters the bay of its own name by several mouths, and the Atrek, are almost the only considerable rivers which it receives on the E. side, though the Oxus, or Amoo, which now enters the sea of Aral, is supposed to have once flowed into it. On the N. and W. its basin is far more extensive. The Ural, the Volga, the Kuma, the Terek, and the Kur here pour their waters into it, and most of them are constantly bringing accumulations of sand, which in some instances, as at the mouth of the Volga, form little islands, projecting several miles from the coast. All this part of the coast, as far S. as the Sulak, is of alluvial formation; thence S. to the penin-

sula of Apsheron it is of tertiary formation, broken by occasional carboniferous strata; and from Apsheron around the S. extremity of the sea, the shores are low and sandy, with lofty hills rising in the background. On the E. and S. E. is found a cretaceous subsoil, covered with moving sands; the surface, with the exception of Cape Karagan, being flat. In fact, the coast generally is so low that most parts are overflowed when the wind sets in strongly from the opposite quarter. Naphtha, or petroleum, is found in immense quantities, particularly in the vicinity of Baku on the peninsula of Apsheron and on the island of Naphthalia, in the bay of Balkan. There is a large export of petroleum to the Tartar and Persian ports on the S. and E. shores of the sea. In May, 1869, there was an extraordinary conflagration caused by the accidental ignition of large naphtha streams flowing on the surface of the sea. The waters are not so salt as those of the ocean, owing to the immense volume of fresh water constantly poured in by the Volga and other large rivers. It is very deep, particularly on the S. shore, where a line of 450 fathoms will not reach bottom; but in the north and off the mouths of the Volga it is quite shallow, with frequent shoals. There are no tides, and the sea has no outlet, the superfluous waters being carried off wholly by evaporation. Extraordinary changes in its level have been noticed, but never explained; according to native accounts, the surface rises and falls several feet in periods of about 30 years. It has long been known that the level of the Caspian is lower than that of the ocean, and in 1812 an attempt was made by Engelhardt and Parrot to ascertain the difference by a series of levellings and barometrical measurements across the Caucasian isthmus to the Black sea. Measurements were made in two places, one of which made the Caspian 348 ft. lower than the Black sea, and the other 301 ft. lower. A survey made by the Russian government in 1836-'7 proved the difference of level to be 84 ft. Sturgeon, sterlets, balugas, salmon, and seals are taken in great numbers.—We know little of the ancient commerce of the Caspian. About the middle of the 13th century much of the trade of W. Europe with India passed over it, Astrakhan being then, as now, its chief port. On the seizure of Constantinople by the Turks commerce was forced into other channels. In 1560 an English company made a fruitless attempt to render it a channel of commerce with Persia and Turkistan. Peter the Great had its coasts explored by Dutch navigators, partly with the view of founding stations for the Indian trade on the Persian seaboard, but his project was not carried out. No Russian conquest was made on the Caspian sea until the time of Catharine II., and it was not till still more recent periods that Russia succeeded in obtaining full control over its trade, which is small, though constantly increasing. The largest class of vessels navigating the Cas-

pian, carrying from 90 to 200 tons, are called *schuyts*, and are built of the timber of the boats that bring breadstuffs down the Volga to Astrakhan. Another class of vessels, of superior sailing qualities, carry from 70 to 140 tons, and are called *raschips*. Besides these, a great number of small craft are employed in coasting, fishing, and as lighters. The Caspian steamboat navigation company was chartered in 1858, and steamboats are now common on the Volga and at all the important ports in the Caspian. Canals uniting the head waters of the Volga with Lake Ilmen and the Duna establish connections between the Caspian and the Baltic. The Russian government has projected a canal to connect the Caspian with the sea of Azov, and then with the Black sea, for which surveys were made in 1855, 1860, 1864, and 1871. The principal ports are Astrakhan and Baku, from which trade is carried on with Astrabad, Balfrush, and other Persian ports on the south, and with Manghishlak, Balkan, &c., on the east. Russia maintains a fleet on the Caspian, and has three fortified settlements on the E. coast.—Dureau-Delamalle's *Géographie physique de la Mer Noire*, Eichwald's *Reise auf dem Kaspischen Meere und in den Kaukasus*, Hommaire de Hell's *Les steppes de la Mer Caspienne*, the *Beschreibung* published by Sawitsch and Sabler, giving their survey of the respective elevations of the Black and Caspian seas (St. Petersburg and Leipsic, 1849), and Petermann's *Mittheilungen*, iii., vii., 1869, contain valuable information on this sea.

CASS, the name of seven counties in the United States. **I.** A S. W. county of Michigan, bordering on Indiana; area, 528 sq. m.; pop. in 1870, 21,094. It has a level surface, diversified by a number of small lakes, and occupied by prairie, oak openings, and dense forests. Iron and limestone are the principal minerals. It is traversed by the Lake Shore and Michigan Southern, the Peninsula, and the Michigan Central railroads. The chief productions in 1870 were 630,271 bushels of wheat, 670,013 of Indian corn, 175,665 of oats, 302,058 of potatoes, 33,078 tons of hay, 443,182 lbs. of butter, 143,913 of wool, and 42,278 of maple sugar. There were 7,142 horses, 5,648 milch cows, 6,702 other cattle, 36,770 sheep, and 22,330 swine. There were 7 manufactories of agricultural implements, 11 of carriages and wagons, 7 of furniture, 5 of iron castings, 7 of saddlery and harness, 5 of tin, copper, and sheet-iron ware, 3 of woollen goods, 3 flour and 24 saw mills. Capital, Cassopolis. **II.** A N. W. county of Indiana, drained by Wabash and Eel rivers; area, 420 sq. m.; pop. in 1870, 24,193. In the vicinity of the rivers are high bluffs; the rest of the surface is generally flat, and divided between prairies in the N. and forests in the S. part. It is traversed by the Wabash and Erie canal, and by the Toledo, Wabash, and Western, and the Columbus, Chicago, and Indiana Central railroads. The chief productions in 1870 were

401,154 bushels of wheat, 312,434 of Indian corn, 90,835 of oats, 55,077 of potatoes, 11,934 of flax seed, 10,516 tons of hay, 310,588 lbs. of butter, and 56,444 of wool. There were 4,989 horses, 4,361 milch cows, 6,181 other cattle, 18,186 sheep, and 14,706 swine. There were 7 flour mills, 31 saw mills, 1 manufactory of cars, 4 of machinery, 9 of carriages and wagons, 5 of furniture, 2 of iron castings, 1 of linseed oil, and 5 of saddlery and harness. Capital, Logansport. **III.** A W. central county of Illinois, bounded N. W. by Illinois river, and N. by the Sangamon, both of which are here navigable by steamboats; area, 350 sq. m.; pop. in 1870, 11,580. The surface is level, and consists of prairies and woodlands; the soil is extremely fertile. It is traversed by the Peoria, Pekin, and Jacksonville, the Springfield and Illinois Southeastern, and the Rockford, Rock Island, and St. Louis railroads; the Jacksonville division of the Chicago and Alton railroad intersects the S. E. corner. The chief productions in 1870 were 139,219 bushels of wheat, 1,146,980 of Indian corn, 168,784 of oats, and 4,136 tons of hay. There were 3,513 horses, 2,281 milch cows, 6,198 other cattle, 4,235 sheep, and 12,685 swine. There were 3 flour and 2 saw mills, 1 paper mill, and 2 manufactories of carriages and wagons. Capital, Beardstown. **IV.** A N. central county of Minnesota, nearly encircled except on the west by the Mississippi, which rises in Itasca lake on its N. W. border; area, 4,750 sq. m.; pop. in 1870, 380. It is watered by numerous streams and lakes, the largest of which is Leech lake, in the N. part. Pine and other timber is abundant. The Northern Pacific railroad passes through the S. part. The estimated value of farm productions in 1870 was \$1,770; of live stock, \$1,360. **V.** A S. W. county of Iowa; area, 576 sq. m.; pop. in 1870, 5,464. It is traversed by the Nishnabotona river, an affluent of the Missouri, and watered by affluents of the Nodaway river. The Chicago, Rock Island, and Pacific railroad passes through it. The chief productions in 1870 were 54,529 bushels of wheat, 235,500 of Indian corn, 23,144 of oats, 13,857 of potatoes, 7,061 tons of hay, and 56,185 lbs. of butter. There were 954 horses, 868 milch cows, 2,398 other cattle, 1,386 sheep, and 1,820 swine. Capital, Lewis. **VI.** A W. county of Missouri, bordering on Kansas, intersected by a branch of the Osage river; area, about 1,000 sq. m.; pop. in 1870, 19,206, of whom 502 were colored. There are numerous springs of good water, and several quarries of limestone and sandstone. The surface is moderately uneven and occupied chiefly by fertile prairies. The Pacific railroad of Missouri crosses the S. E. corner. The chief productions in 1870 were 205,789 bushels of wheat, 1,711,952 of Indian corn, 262,472 of oats, 82,859 of potatoes, 12,100 tons of hay, 252,508 lbs. of butter, 22,680 of wool, and 19,281 of tobacco. There were 8,053 horses,

1,441 mules and asses, 5,366 milch cows, 13,514 other cattle, 9,187 sheep, and 33,140 swine. There were 6 flour and 7 saw mills, and 5 manufactories of saddlery and harness. Capital, Harrisonville. **VII.** A S. E. county of Nebraska, bounded N. by the Platte river, and separated from Iowa on the east by the Missouri; area, 570 sq. m.; pop. in 1870, 8,151. It is well watered and fertile, the surface being undulating prairie. The Burlington and Missouri River railroad traverses it. The chief productions in 1870 were 224,670 bushels of wheat, 674,558 of Indian corn, 137,986 of oats, 78,107 of potatoes, 11,971 tons of hay, and 171,262 lbs. of butter. There were 3,310 horses, 2,748 milch cows, 4,370 other cattle, 2,098 sheep, and 7,419 swine. There were 8 flour and 2 saw mills, and 3 manufactories of saddlery and harness. Capital, Plattsmouth.

CASS, Lewis, an American statesman, born at Exeter, N. H., Oct. 9, 1782, died in Detroit, Mich., June 17, 1866. He was the eldest son of Jonathan Cass, who served in the revolution and rose to the rank of major in the army. In 1799 he was stationed at Wilmington, Del., where his son found employment as a teacher. In the following year the family went to Marietta, Ohio, where Lewis studied law, and in 1802 he was admitted to the bar and began to practise in Zanesville. In 1806 he married Elizabeth Spencer, of Wood co., Va., and shortly afterward was elected a member of the legislature. In this capacity he drew up the address to Jefferson embodying the views of the legislature on Aaron Burr's expedition, and drafted the law under which Burr's boats and provisions, built and collected in Ohio, were seized. From 1807 to 1813 he was state marshal. In the war of 1812 he was colonel of the third Ohio volunteers under Gen. Hull, and after Hull's surrender was appointed colonel of the 27th infantry, and was shortly afterward promoted to the rank of brigadier general. At the close of the campaign he was in command of Michigan, and in October, 1813, was appointed governor of the territory. He acted as governor, and *ex officio* as superintendent of Indian affairs, for 18 years, during which time he negotiated 22 treaties, secured by cession of different tribes immense tracts of land in the northwest, instituted surveys, constructed roads, built forts, and organized counties and townships. In 1815 he purchased for \$12,000 a homestead tract of 500 acres in Detroit, which the subsequent growth of the city made immensely valuable. In 1820, in company with Schoolcraft and others, he explored the upper lakes and the head waters of the Mississippi, traversing 5,000 miles. The results of this and of subsequent expeditions were published in the "North American Review" in 1828-'9. In 1831 President Jackson nominated him secretary of war, and he was at the head of the war department during the first two years of the Florida war, 1835-'6. In

1836 he was sent as minister to France. In this capacity he settled the indemnity dispute by obtaining the interest withheld when the principal was paid. In 1837 he embarked at Marseilles in the frigate *Constitution* for Egypt via Constantinople, following the coast, stopping at the principal ports, and making excursions into the interior. He was on excellent terms with Louis Philippe, of whose character he gave a favorable account in his "King, Court, and Government of France," published in 1840. The most marked incident of his diplomatic career was his attack on the quintuple treaty for the suppression of the slave trade, which led to his resignation in 1842. In January, 1845, he was elected United States senator from Michigan, which place he resigned on his nomination, May 22, 1848, as democratic candidate for the presidency. A division in the democratic party in New York gave that state to Gen. Taylor, and secured his election by a majority of 36 electoral votes. In June, 1849, Cass was re-elected to the senate for the remainder of his original term. In the next session he vigorously opposed the Wilmot proviso, though he was instructed by the legislature of Michigan to vote for it. In 1850 he was a member of Clay's compromise committee, but did not vote for the fugitive slave bill. He was again elected a senator for six years from March 4, 1851. In the democratic convention at Baltimore, in May, 1852, he was a candidate for the presidential nomination, but was unsuccessful. In 1854 he voted for Douglas's Kansas-Nebraska bill proposing a repeal of the Missouri compromise, but including a provision embodying Cass's suggestion, in the famous Nicholson letter, to leave to the inhabitants of the territories the power to regulate their own institutions, subject only to the constitution of the United States. Subsequently he declined to obey the instructions of the Michigan legislature as to his votes on the Kansas question. In the democratic convention at Cincinnati, in May, 1856, he was not a candidate, and warmly concurred in the nomination of Mr. Buchanan, who on his accession to the presidency in 1857 nominated Cass as secretary of state. In December, 1860, when Buchanan refused to reinforce Major Anderson and re-provision Fort Sumter, he promptly resigned and closed a public career of 54 years. During the war he warmly sympathized with the national cause, and lived to see its complete success. He was a man of much ability and of the purest integrity, a fine scholar, and an effective public speaker. In private life he was distinguished for a generous hospitality, which his great wealth enabled him to dispense. Besides his published works above noticed, he was author of an "Inquiry respecting the History, Traditions, Languages, &c., of the Indians living within the United States" (Detroit, 1823), and of several historical and scientific sketches and addresses.—See "Life

and Times of Lewis Cass," by W. L. G. Smith (New York, 1856).

CASSAGNAC. See GRANIER DE CASSAGNAC.

CASSANDER, king of Macedon, son of Antipater, born about 354 B. C., died in 297. History gives no account of his life previous to 323, in which year he undertook a journey to Babylon, in order to defend his father Antipater from the accusations which had been made against him before Alexander. Cassander's pride, and his contempt for the servility he saw exhibited at the conqueror's court, are said to have offended that monarch and caused him to treat his visitor with indignity. Whatever may have been the cause, it seems certain that the interview between the two led Cassander to a violent hatred of the great ruler, so undisguised that when Alexander died but a short time after, Cassander's name was everywhere connected with a story which attributed his death to poison. When Antigonus was sent by Antipater against Eumenes in 321, Cassander was appointed chiliarch, or second in command of the expedition; and on the death of his father in 319, he was confirmed in this office by Polysperchon, whom his father, ignoring the claims of his son, had left regent of Macedonia. Indignant at being kept in a secondary position, he declared war against Polysperchon, having first formed an alliance with Ptolemy Lagi and Antigonus. Polysperchon had apparently won the favor of the Greek cities by declaring them independent of Macedonia, and Athens was especially well disposed toward him. He had also the influence of Olympias on his side; and Antigonus, whom he considered the most formidable of his opponents, was at war with Eumenes in Asia. But Cassander's general Nicanor held Munychia and the Piræus, the port fortresses of Athens. Polysperchon, accompanied by the royal family (Alexander's), began a march into Attica to attack these; but while he delayed in Phocis, where by a treacherous action (see ΠΡΟΣΤΟΝ) he endeavored to render more secure the allegiance of the Athenians, Cassander suddenly appeared near Athens and occupied the Piræus with a large force. Polysperchon laid siege to it, but meeting with little success, he left his son Alexander to conduct the attack and went on into the Peloponnesus. Here he met with little resistance until he attacked Megalopolis, whose citizens repulsed his army at the same time that his fleet was destroyed by that of Cassander in the Hellespont. These defeats caused the Greek states to go over at once to the side of the victor, who treated Athens with clemency, and won friends throughout Greece by his justice and tact. In the mean time he had formed an alliance with the wife of King Arrhidæus, Eurydice, an energetic and intriguing queen, who had determined to free herself from Polysperchon's oppression, and had herself raised an army with which she did Cassander good service in holding Macedonia. While he was pursuing his conquest in Greece, and just as he

had laid siege to Tegea, he received news that Eurydice and her husband, with Cassander's brother Nicanor and 100 of his friends, had been murdered by the orders of Olympias. He at once hastened homeward, cut off Olympias from her allies, besieged her in Pydna during the winter of 317, captured her in the spring, and at once had her put to death, in violation, it is said, of his special agreement. He now imprisoned Alexander's son, Alexander Ægus, and his mother Roxana, and further prepared his way to the royal power by marrying Thessalonica, Alexander's half sister. It was probably within a year of his marriage that he rebuilt the two cities of Therma and Potidæa, naming them Thessalonica and Cassandria. In 315 he returned to Greece, and began the rebuilding of Thebes, which Alexander had destroyed 20 years before. Polysperchon and his son had during his absence retaken some of the towns of the Peloponnese, but Cassander regained possession of them without difficulty; and within the next year he and Polysperchon ended their rivalry by forming an alliance with several other leaders against the now formidable power of Antigonus. War was begun in 313; but Antigonus by specious promises gained the allegiance of nearly all the Greek states, and two years' conflict which followed was unfavorable to Cassander and his friends. In 311 peace was declared; and during that year Cassander made further way for his ambition by ordering the murder of his two prisoners, Roxana and Alexander Ægus. In 310 war again broke out, and now Polysperchon once more opposed his old enemy, putting forward Hercules, another son of Alexander, as the proper heir to the throne; but Cassander won him over by bribes, and induced him in 309 to put to death his protégé and his mother. The ambitious ruler nevertheless lost ground rapidly; Corinth, Sicyon, and Athens, the only towns now subject to him in Greece, fell into the hands of the enemy in 308 and 307; a long series of defeats and indecisive battles followed; the war was carried into Asia without much change in its aspects; and it was only through the mistaken action of Demetrius, the son of Antigonus, who by going to his father's aid in Asia left Greece exposed, that affairs suddenly changed, and Cassander acquired a lasting advantage. The battle of Ipsus, in 301, in which Antigonus was killed, gave the allies a final victory; and Cassander, Ptolemy, Seleucus, and Lysimachus divided the dominion of the dead king among them, Cassander receiving Macedonia and Greece. His remaining years were occupied with schemes for wider conquest. He invaded the island of Corcyra about 299, but was almost immediately driven from it by Agathocles of Syracuse. In 298 he began the carrying out of plans for gaining complete possession of those cities of southern Greece which still held out against him; but his death occurred before he had gained any considerable success.

CASSANDER, George, a Flemish theologian, born in the island of Cadsand, Zealand, in 1515, died Feb. 3, 1566. He officiated for some time as professor of divinity at Bruges and Ghent, and gained a high reputation by his various attainments. In 1561 he published a treatise designed to reconcile the Catholic and Protestant theologians, which was attacked by Calvin, but favorably received by the emperor Ferdinand and other German princes, the emperor encouraging him to persist in his conciliatory task. In 1565 he published a famous work entitled *Consultatio de Articulis Fidei inter Papistas et Protestantos Controversis*, in which he reviewed the controverted articles of the Augsburg confession. He was sincerely attached to the Roman Catholic faith; but he was accused of taking too favorable a view of the points brought forward by the Protestants, and several of his writings were condemned by the council of Trent. His collected works were published in Paris in 1616.

CASSANDRA (called also **ALEXANDRA**), a Trojan princess, daughter of Priam and Hecuba. Apollo, enamored of her, permitted her to ask of him whatever she desired as a reward for her complaisance. She begged for the gift of prophecy; but when the god had bestowed it upon her, she refused to keep her promise to him. Thereupon Apollo, unable to withdraw from her the prophetic art, ordained that her predictions should never be believed. In vain she foretold that the abduction of Helen would cause the ruin of Troy, counselled the making of peace with the Atridae, announced to Priam, Paris, and the Trojan people the fate which awaited them, and opposed the reception of the wooden horse. On the night of the capture of Troy she took refuge in the temple of Pallas, but was torn away from the statue of the goddess by Ajax, son of Oileus. She fell by lot as a slave to Agamemnon, who, carried her to Greece; and, after fruitlessly advising that prince of the fate reserved for him, she perished with him in the massacre plotted by Clytemnestra. She is an important personage in Greek poetry, and is the heroine of a poem by Lycophron, celebrated for its obscurity.

CASSANO. I. A town of S. Italy, in the province of Cosenza, 10 m. W. of the gulf of Tarento, on the railroad which skirts the E. shore of Calabria; pop. about 8,000. It is built in the concave recess of a steep mountain, round an isolated rock, on which are the ruins of an ancient castle. It is the see of a bishop, and contains a cathedral, four convents, and an episcopal seminary; hot sulphurous springs and plaster and stone quarries are in the vicinity. The inhabitants are principally employed in the manufacture of macaroni, leather, table linens, and fabrics of cotton and silk. It is supposed to stand on the site of the ancient Cosa; according to some authorities, however, the neighboring village of Civitá occupies the real site of the ancient town. **II.** A town of N. Italy, on the Adda, 16 m. N. E. of Milan; pop. about

3,500. A battle was fought here, Sept. 16, 1259, which resulted in the defeat and capture of the tyrant Ezzelino. On Aug. 16, 1705, a victory was gained here by the French under Vendôme, over the imperial troops under Prince Eugene; and on April 27, 1799, the French, under Moreau, were defeated here by the Russians and Austrians, under Suvaroff.

CASSATION, Court of, the highest court of appeal in France. It was established by the constituent assembly toward the close of 1790, under the name of *tribunal de cassation*, with a view of putting an end to the confusion that had so largely prevailed in the judiciary system of the country, and of imparting to the whole jurisdiction a spirit of unity, without endangering the independence of the inferior courts. In 1804 the name of *cour de cassation* was given to the court, which it still retains. The functions of the court are not to go into the facts, but simply to revise the proceedings of the inferior courts, and any decision taken by the court of cassation is considered final and binding. It is composed of a president, 3 vice presidents (*présidents de chambre*), 45 counsellors, an attorney general (*procureur général*), 6 assistant attorneys general (*avocats généraux*), and a chief clerk (*greffier en chef*); and only 60 advocates are permitted to plead before the court. The president and counsellors are named by the government for life; the other officers are removable at pleasure. The court is divided into three chambers, one of appeals in civil and one in criminal cases, and the chamber of requests, a sort of preliminary tribunal, which decides on the *locus standi* and admissibility of the appeal.

CASSAVA, the meal, and bread made from it, obtained from the roots of several species of the genus *manihot* (from the Indian *manioe*),

Cassava (*Manihot utilissima*).

plants of the family of the *euphorbiaceæ*, which grow in the West Indies, South America, and Africa. Three species are described, but under different names by different botanists. The

genus, formerly included in the *jatropha* of Linnæus, was separated by Kunth, and called *janipha*; and the common species was designated as *J. manihot*, of which two varieties, the sweet and bitter, are distinguished. But later authorities designate the genus as *manihot*, and the common species as *M. utilissima*, another as *M. aipi*, and a third as *M. janipha*. The first is the bitter cassava, indigenous to Brazil, and cultivated in other parts of South America. It is a shrub 6 or 8 ft. high, with a large tuberous root, which sometimes weighs 30 lbs. This root contains a large proportion of starch, which is associated with a poisonous milky juice, containing hydrocyanic acid and a bitter acrid principle. The other two species do not possess this poisonous juice. All are used alike for the preparation of the meal. The root is well washed, then scraped or grated to a pulp, and this, when of the poisonous kind, is thoroughly pressed in order to remove the juice; but even if some of this is left in the meal, it escapes by its volatility in the process of baking or drying the cakes upon a hot iron plate. Afterward dried in the sun, the cassava is kept as food, to be mixed with water and baked like flour in large thin cakes. These are a coarse, cheap kind of bread, much used by the negroes and poorer whites, in which the ligneous fibre is plainly visible. Its nourishing qualities consist in the starch of which it is principally composed. The expressed juice also furnishes by deposition a very delicate and nearly pure starch, when left to stand for some time. Well washed with cold water, and afterward dried, this is the tapioca of commerce, sometimes called Brazilian arrowroot.

CASSEL, a town of France, department of Le Nord, on the railway from Lille to Dunkirk, 28 m. N. W. of Lille; pop. in 1866, 4,242. It is situated on an isolated hill 600 ft. high, commanding an extensive view, and has manufactories of lace, linen thread, and hosiery, breweries, tanneries, dye houses, and a considerable trade in cattle. It was the ancient capital of the Morini, and was known to the Romans as Castellum. It was strongly fortified during the middle ages. In 1071 Philip I. of France was defeated here by Robert the Frisian, count of Flanders; in 1328 Philip VI. won a complete victory over the Flemish troops; and in 1677 Philip, duke of Orleans, brother of Louis XIV., defeated here the prince of Orange.

CASSEL, or **Kassel**, a city of Germany, capital of the Prussian province of Hesse-Nassau, and of the district of Cassel, formerly the electorate of Hesse-Cassel, situated on the river Fulda, 90 m. N. N. E. of Frankfort-on-the-Main; pop. in 1871, 46,375, of whom about 5,000 were Roman Catholics, 1,500 Jews, and the remainder Protestants. It is connected by railway directly with Frankfort and Hanover, and thence with the rest of Germany. It is divided into the old town, the lower new town, and the upper new town, and has 10 Protestant churches, a Catholic church, and a synagogue. In St.

Martin's church are the tombs of many of the electors. The city contains the government buildings, the former electoral palace, a theatre, an observatory, and other fine edifices. The

Wilhelmshöhe.

museum, the finest building in Cassel, comprises collections of pictures and natural history, a cabinet of curiosities, containing a vast collection of watches and clocks from the earliest invented, and a library of about 90,000 volumes. The Friedrichsplatz, with a statue of the elector Frederick I., who was the founder and patron of the principal art collections of Cassel, is one of the most admirable public squares in Europe; and there are 15 other public squares. The public gardens are charming, especially that of Wilhelmshöhe, 3 m. distant, in which the summer palace is situated. Here is the cascade of the Karlsburg, consisting of a flight of stone steps extending 900 ft. up a hill on which is a colossal statue of Hercules. After the battle of Sedan, Napoleon III. was a prisoner at Wilhelmshöhe until March 19, 1871. There are manufactures of cotton, silk, and woollen fabrics, leather, hats, carpets, kid gloves, and porcelain; and the place is the main emporium of the trade of Hesse-Cassel. Two fairs and a wool market are held here annually.

CASSEL, **Paulus Stephanus Selig**, a German clergyman and author, born of Jewish parentage in Glogau, Silesia, Feb. 27, 1827. He was educated in both the Roman Catholic and Protestant gymnasia of Schweidnitz, completed his studies of history in Berlin under Ranke, became a journalist, and in 1855 a Protestant. Subsequently he was director of the royal library and secretary of the academy at Erfurt, the government giving him the title of professor. He removed to Berlin in 1859, and served in the Prussian chamber of deputies from 1866 to the end of 1867, when he declined a reelection to become minister of Christ church, which position he continues to hold (1873). His treatises on the history of Erfurt were followed in 1848 by his *Magyarische Alterthümer*, and in 1851 by an extensive historical article

on the Jews in Ersch and Gruber's cyclopædia, and a political disquisition, *Von Warschau bis Olmütz*, which attracted much attention. He has written also on various literary subjects; and his more important theological works are *Weihnachten* (1862), *Die Bücher der Richter und Ruth* (1865), *Sunam* (1869), and *Das Evangelium des Sohnes Zebedäi* (1870). His works for the young have passed through numerous editions, and he has also acquired eminence as a lecturer on the œcumenical council and papal history (1869-'70), and on the Franco-German war.

CASSIA, the bark of the *cinnamomum cassia*, an inferior quality of cinnamon which is often mixed with the genuine article. (See CINNAMON.)—Cassia is also a genus of plants of the family *leguminosa*. Several species of this

Cinnamomum cassia.

genus furnish the officinal senna. One species native to this country is the source of the drug called American senna. The pod of *cassia fistula*, and perhaps an allied species, is employed to some extent as a laxative.

CASSIANUS, Johannes, a founder of monastic institutions, believed to have been born about 350, and to have died in Marseilles about 433. According to other accounts, he was a native of Greece, born about 360, and died about 448. He went when young to the Holy Land, remained some time in Bethlehem, spent many years among the ascetics of Egypt, was ordained about 403 as deacon by Chrysostom at Constantinople, and sent on a mission to Rome relative to the controversy with the Arians. Soon afterward he founded at Marseilles a nunnery and the abbey of Saint Victor, which is said to have contained during his time 5,000 inmates. His *De Institutis Conobiorum* and *Collationes Patrum Sceticorum* constitute a code of monastical institutions, which, though strenuously opposed by St. Augustine, acquired great popularity, and was subsequently much admired by Thomas Aquinas, by the recluses of Port Royal, who adopted his regulations as the model of their monastic life, and by Arnaud d'Andilly, who embodied the ideas

of Cassianus in his *Vie des pères du désert*. He was eventually canonized, and his anniversary, July 23, was long celebrated at Marseilles. The best edition of his collected works is that reprinted at Leipsic in 1733.

CASSIN, John, an American ornithologist, born near Chester, Penn., Sept. 6, 1813, died Jan. 10, 1869. In 1834 he took up his residence in Philadelphia, and, excepting a few years partially given to mercantile pursuits, devoted himself to the study of ornithology. He contributed descriptions of new species and synoptical reviews of various families to the "Proceedings" and the "Journal" of the Philadelphia academy of natural science. His more elaborate publications are: "Birds of California, Texas," &c. (Philadelphia, 1855); "American Ornithology" (1856), containing descriptions and figures of all North American birds not given by former American authors, after the manner and designed as a continuation of the works of Audubon, with 50 colored plates; "Mammalogy and Ornithology of the United States Exploring Expedition;" "Ornithology of the Japan Expedition;" "Ornithology of Gilliss's Astronomical Expedition to Chili;" the chapters on rapacious and wading birds in the "Ornithology of the Pacific Railroad Explorations and Surveys;" and the ornithology of the "Iconographic Encyclopædia." His works are the result of careful research, and are especially valuable for their descriptions and classifications of many birds not given in the previous works of Wilson and Audubon.—He was of a Quaker family, several members of which have distinguished themselves in naval and military service. His great-uncle, JOHN CASSIN, a commodore in the American navy, conducted the defence of Philadelphia in the war of 1812. His uncle, STEPHEN CASSIN (1782–1857), also a commodore, served under Com. Preble in the war with Tripoli, and for his bravery in the action on Lake Champlain in 1814, under Com. McDonough, was rewarded by congress with a gold medal.

CASSINI, a family of Italian and French astronomers, four members of which were directors of the Paris observatory for the first 122 years of its existence. **I. Giovanni Domenico**, born at Perinaldo, near Nice, June 8, 1625, died in Paris, Sept. 14, 1712. While in college at Genoa he gained considerable reputation by his Latin verses; but his attention having been turned to mathematics, he abandoned poetry. He went to Paris as secretary in the suite of Lercaro, afterward doge of Genoa, who was then the head of an embassy to the court of Louis XIV. After the return of the embassy he accompanied Lercaro to his estates in Lombardy, and while there he devoted some time to the study of astrology, which led him to his lifelong pursuit of astronomy. In 1644, at the invitation of the marquis Malvasia, he went to Bologna, and in 1650 was appointed professor of astronomy in the university there. The marquis had built an observatory at the villa of

Pansano near Modena, and here Cassini made observations upon the comet of 1652 from which he published his first work. In the following year the church of St. Petronia in Bologna, where Ignazio Dante in 1575 had established a meridian line and gnomon, was undergoing repairs, and Cassini obtained the privilege of correcting and lengthening this line. He was very successful, and made observations in regard to the obliquity of the ecliptic, refraction, and parallax, which subsequent observations have shown to be very close approximations to exactness. In 1656 he published his tables of the sun founded upon these observations. In 1657 he was appointed superintendent of the Po for the city of Bologna, and he was afterward employed in many public duties by different cities and by the pope. He also found time to make a great number of observations upon insects, experiments upon the transfusion of blood, a subject which then attracted great attention, and to continue his astronomical observations. While at Ferrara he conceived the idea of a chart to represent the different appearances of an eclipse of the sun at various places on the surface of the earth; but the inquisitor of that city forbade its publication on account of its novelty. In 1665, at Città della Pieve in Tuscany, by means of a telescope furnished by Campani, he observed the shadows thrown upon the surface of Jupiter by his satellites when they pass between the planet and the sun, and distinguished them from the fixed spots. Having compared his own observations with those of Galileo, he constructed his first tables of the satellites. He very nearly approximated the truth in his calculations of the time of rotation of Jupiter, Venus, Mars, and the sun; and these discoveries exalted his reputation above that of any other astronomer then living. Though they really indicated nothing more than the use of good instruments by a careful and accurate observer, yet they were capable of being stated in definite terms which everybody could understand; and while the sublime discoveries of Copernicus and Newton were slowly struggling for recognition, all Europe was filled with the praises of the man who had laid open and stated in numbers the secrets of the heavens. In 1666 Colbert, chief minister of Louis XIV. of France, founded the royal academy of sciences and projected an observatory. He invited Cassini to take up his residence in Paris, offering him a pension equal to the emoluments of all the offices he held in Italy. Cassini arrived in Paris April 4, 1669, and on Sept. 14, 1671, commenced his observations. In this and the following year he discovered the third and fifth satellites of Saturn. In 1673 the Bolognese government requested him to return to that city, but Colbert persuaded him to remain in France. Cassini took out letters of naturalization as a French subject, and the same year married a French lady. Henceforth his time was mostly occupied in making observations and recording their re-

sults. His explanation of the lunar libration was more complete and accurate than any previously given, and is considered one of his finest achievements. He was the first who carefully observed the zodiacal light, although he did not, as is frequently asserted, discover it. In 1684 he discovered the first and second satellites of Saturn, and a medal was struck in commemoration of the event, with the legend *Saturni Satellites primum cogniti*. In 1693 he published new tables of the satellites of Jupiter, which were a considerable improvement upon those which he had previously published in 1668. He had long been in possession of all the data necessary to determine the velocity of the transmission of light; but when the announcement of the discovery was made by Olaus Römer, Cassini rejected it. He revisited Italy in 1695, accompanied by his son. The survey of an arc of the meridian of Paris, which had been commenced in 1669 by Picard, and continued to the north of Paris by La Hire in 1683, was completed by Cassini to the south as far as Roussillon in 1700. He continued his observations until a few years before his death, when he became totally blind. Cassini left a great number of writings, some of which have never been published; but very many appeared in the *Journal des Savants* and in the *Mémoires de l'Académie*. None of them are now consulted except in so far as they may contain records of facts and observations. He nowhere gives evidence of any acquaintance with the writings of Newton, and it has never been ascertained whether he rejected or adopted the Copernican theory of the solar system. He left an autobiography, which was published in 1810 by his great-grandson Cassini de Thury. **II. Jacques**, son of the preceding, born in Paris, Feb. 18, 1677, died on his estate of Thury, April 16, 1756. Some papers on optics by him and an elder brother, who was killed at the battle of La Hogue, were published in 1691. In 1694, when only 17 years of age, he was chosen a member of the academy of sciences, and the following year accompanied his father to Italy. He then travelled in Holland and England, where he made the acquaintance of Newton and many other distinguished men, and in 1696 he was made a member of the royal society. He participated with his father in the survey of the meridian, which he continued to Mt. Canigou in the extreme south of France, and afterward northward to Dunkirk. On the death of his father he succeeded him at the observatory, and was *maître des comptes*. In 1720 he published a work on the magnitude and form of the earth. He determined the times of revolution of the satellites of Saturn then known, first observed the inclination of the orbit of the fifth (now the seventh), and determined very nearly the variation of the obliquity of the ecliptic and the length of the year. In 1740 he published *Éléments d'astronomie*. Like his father, he was an excellent observer, but little of a philosopher. He seems to have been inclined toward

the Copernican system, to have had hardly any acquaintance with the theories of Newton, and to have been ignorant of the discovery of aberration by his contemporary Bradley. **III. César François** (CASSINI DE THURY), son of the preceding, born in Paris, Jan. 17, 1714, died Sept. 4, 1784. He became a member of the academy of sciences in his 22d year, assisted his father in the survey of the meridian, and succeeded him as director of the observatory and *maître des comptes*. His greatest work was the immense topographical map of France, upon which he labored for a large part of his life. It was finished by his son. Like his father and grandfather, he was an accurate and industrious observer, but contributed nothing to the advancement of astronomical science. **IV. Jacques Dominique**, count de Thury, son of the preceding, born in Paris, June 30, 1748, died there, Oct. 18, 1845. In 1770 he published an account of a voyage made by order of the king to test the chronometers of Le Roy, and the same year was admitted a member of the academy of sciences. He succeeded his father as director of the observatory. In 1787 he was associated with Méchain and Legendre in the operations to connect by a series of triangles the observatories of Greenwich and Paris. He completed the great map of France which his father had left unfinished, and on Oct. 13, 1789, he presented it to the national assembly as an aid in the new division of France into departments. In 1793 the national convention decreed that the observatory should no longer be under the control of one person, but of four, who should each serve in rotation for a year. Cassini and three of his pupils were appointed. He refused to submit to this, and on Sept. 6 of the same year he resigned. He was ordered to quit the observatory within 24 hours, and the next year he was imprisoned for seven months. On recovering his liberty he retired to his estate, abandoned astronomy entirely, and refused to take any part in the scientific operations undertaken by the government. **V. Alexandre Henri Gabriel**, a French botanist, son of the preceding, born in Paris, May 9, 1781, died of cholera, April 16, 1832. He commenced astronomical studies at an early age, but soon abandoned them and devoted himself in great measure to the study of botany, and published a large number of papers upon various parts of that science. He also held several judicial offices, being in the latter years of his life a member of the court of cassation. In 1827 he was made a member of the academy of sciences, and in 1830 a peer of France.

CASSINO, a game at cards in which four are dealt to each player, four being also placed on the board. There are generally four players. The greatest number of cards counts 3 points, and of spades 1; the 10 of diamonds, great cassino, 2; the 2 of spades, little cassino, 1; and each of the aces 1. The object is to take as many cards as possible. A player may take from the board any card corresponding to one

in his hand, or any cards whose combined spots equal the number of spots on any card in his hand. Thus, a 10 in the player's hand will take a 10 from the board, or any number of cards which can be made to combine into 10. The name of the play is derived from the societies' rooms in Italy, and continental Europe generally, under the name of casinos, where probably the name originated.

CASSINO, Monte. See CASINO.

CASSIODORUS, Magnus Aurelius, an Italian statesman, author, and ascetic, born at Scylacium about 468, died about 560. He was of an ancient and wealthy Roman family. In his youth he distinguished himself by his talents, and was appointed to high offices by Odoacer, king of the Heruli, the first barbarian king of Italy. After Theodoric, king of the Ostrogoths, had overcome and supplanted Odoacer, Cassiodorus for many years, and under various titles, was prime minister of the Gothic kingdom. When Theodoric in his old age began to persecute the leading Latins in his service, Cassiodorus resigned his situation and dignities, and retired to his estates. After the death of Theodoric he was recalled to power, and served with distinction and fidelity Amalasontha, Athalaric, Theodatus, and Vitiges. Upon the temporary triumph of the emperors of the East, being now 70 years of age, he retired again to the monastery of Viviers which he had founded in Calabria. In this retreat he passed the remainder of his days, which were prolonged until he was nearly a century old. His career as a historian and man of letters began when his career as a statesman ended. He taught his monks to labor in the fields as husbandmen, and to devote themselves to the copying of ancient manuscripts, then perishing rapidly under the effects of barbarian ascendancy and Roman neglect. This monastery was taken as a model for others founded in all parts of Christian Europe. His arrangement of the branches of a liberal education into grammar, rhetoric, and dialectics (the *trivium*), and arithmetic, geometry, astronomy, and music (the *quadrivium*), was accepted throughout the middle ages, and long after, as the only true programme of a liberal education. His writings on education form a considerable part of his literary remains. His history of the Goths in 12 books has not survived, but the epitome of the same by Jornandes is extant, and is an invaluable authority. Equally important in a critical point of view are his state papers in 12 books, which are the chief authority upon the internal condition and government of Italy during the period of Ostrogothic rule. The style is very florid and affected, the language very corrupt. He also wrote a universal history down to 519, and an ecclesiastical history from the era of Constantine down to the time of Theodosius the Younger. These works enjoyed great consideration during the middle ages, but since the revival of learning have fallen into oblivion. The first edition of his

works was published at Paris in 1584; the latest and best is that published by D. Garet at Rouen (2 vols. folio, 1679), and reprinted at Venice (1729). There are three biographies of Cassiodorus: one in Latin, prefixed to Garet's edition of his works; one in French by Saint-Marthe, Paris, 1695; and one in German by De Buat, in the first volume of the transactions of the royal academy of Munich.

CASSIOPEIA, a northern constellation, easily recognized by the form, a letter W, on the opposite side of the pole from the Great Bear; named from the wife of Cepheus, king of Ethiopia, and mother of Andromeda. The constellation was distinguished in 1572 by a brilliant temporary star which shone for 18 months and then disappeared.

CASSIQUIARE, or *Cassiquiare*, a remarkable river of Venezuela, deep and extremely rapid, which serves as the connecting link between the Orinoco and the Rio Negro. It furnishes the only example in the world of a bifurcation forming in the very heart of a continent a natural water communication between two great river valleys. It leaves the Orinoco about 20 m. W. of Esmeralda, and is at first scarcely 250 ft. broad; and after a S.W. course of nearly 130 m. it joins the Negro near the little town of San Carlos, its breadth having there reached over 1,500 ft. By means of the Cassiquiare canoes can penetrate with facility from the south of Brazil, from Peru and Bolivia, and even from the Argentine Republic, to Caracas through the Amazon and Orinoco and their various affluents.

CASSIS, in conchology, the name of a genus of univalve shells, including the species known as helmets. (See HELMET SHELL.)

CASSITERIDES, or the *Tin Islands* of the Greek and Roman writers, are supposed with much probability to be the modern Scilly islands near the coast of Cornwall, England. The Phœnicians, who discovered these islands and who kept the knowledge of them for a long time from other nations, traded there for tin with the inhabitants of the neighboring peninsula of Cornwall, where the tin was produced from mines, and was brought to the islands and sold to the foreign merchants. The islands themselves produced no tin. By a natural confusion of ideas the term Cassiterides or tin islands came in time to be applied to Cornwall itself, at least before the Roman settlement in Britain, when the true situation of the tin mines became known. (See SCILLY ISLANDS.)

CASSIUS. I. Longinus Caius, the leader of the conspiracy against Cæsar, died in 42 B. C. In 53 he was quæstor in the campaign against the Parthians, and distinguished himself by military skill, particularly after the death of Crassus, in the defeat at Carrhæ. Having collected the remains of the army, he defended Syria, and won in the next two years two victories over the Parthians. After his return to Rome he was tribune of the people, embraced the party of the senate at the outbreak of the

civil war, and followed Pompey, whose fleet he then commanded, in his flight. After the defeat at Pharsalia (48), he led the fleet to the Hellespont, but having fallen in with Cæsar, he surrendered. Cæsar pardoned him, made him prætor, and promised him the province of Syria. At the same time Cassius was engaged with Brutus in forming a conspiracy against the dictatorial rule and the life of his benefactor. Cæsar fell on the ides of March, 44, and the senate rewarded his murderers with provinces. Cassius received Syria, where he defeated his opponent Dolabella, plundered its cities to provide means for the war against Antony and Octavius, and returned with Brutus to Macedonia. The two ensuing battles of Philippi (42) ended their lives, with the hopes of the Roman republicans. In the first, Antony defeated the wing of Cassius, who, mistaking the cavalry of the victorious Brutus hastening to his relief for that of Octavius, killed himself, as Plutarch says, with the dagger which wounded Cæsar. In the second, Brutus, who mourned him as the last of the Romans, followed his example. **II. Cassius Parmensis**, so called from his birthplace, the city of Parma, was also one of the conspirators against Cæsar, after whose death he adhered to the aristocratic republican party of Brutus and his namesake Cassius, and fought on their side until their defeat at Philippi. He subsequently joined Pompey, and afterward surrendered himself to Antony, whose fortunes he followed until after the battle of Actium; he then retired to Athens, where he was put to death by order of Augustus. He was a poet of some eminence, not to be confounded with Cassius of Etruria, who is ridiculed by Horace in his *Sermones* for his facility and poverty of composition, and is believed to be the person alluded to by Shakespeare as torn to pieces in the streets of Rome by the rabble immediately on the celebration of Cæsar's funeral rites, and the raising of the people by Antony.

CASSIUS, Dion. See **DION CASSIUS**.

CASSIUS, Purple of, a pigment used for coloring porcelain and glass by fusing it with these substances. It is a precipitate obtained by adding protochloride of tin to a solution of chloride of gold. The purple powder thrown down is an obscure compound of sesquioxide of tin and oxide of gold. It contains of metallic gold 39·82 per cent. Its production is a test of the presence of protoxide of tin.

CASSOCK, a close garment resembling a long frockcoat, made of cloth or silk with a single upright collar, worn under the surplice by clergymen of the Roman Catholic and Anglican churches. In the Roman church it varies in color, being black for priests, purple for bishops, scarlet for cardinals, and white for popes. In the Anglican church it is always black, and worn by all orders of the clergy.

CASSOWARY (*casuarius galeatus*, Vieill.), a bird of the ostrich family, the only species of the genus. The bill of the cassowary is long,

compressed, and curved to the tip, the upper mandible overlapping the under. The wings consist of five strong rounded shafts without webs; the tail is not apparent; the tarsi are long and robust, and covered with large scales; the toes are three in number, all directed forward; the inner toe is armed with a very long powerful claw. The head and base of the bill are surmounted by an elevated compressed casque, or bony helmet; the head and neck are denuded of feathers, the skin being of a blue and violet color, with two fleshy wattles in front. It is a heavy massive bird, about 5 ft. high; the plumage is of a blackish color, the feathers being loose, and resembling delicate hairs; the feathers which take the place of the tail are pendent. The cassowary is a stupid, gluttonous bird, living on fruits, herbs, and occasionally on small animals; it is incapable of flight from the imperfect development of the wings, but it runs with great rapidity, and de-

Cassowary (*Casuarius galeatus*).

fends itself by means of its powerful feet. It lives in pairs in the forests of the Moluccas, of New Guinea, and other islands in the Indian archipelago; in some places it is domesticated. The female lays three greenish spotted eggs, on the bare ground, on which she sits during the night for a month; the young are of a red color, mixed with grayish. The cassowary, though it approaches the structure of common birds in the shortness of the intestines, and in the want of the stomachal sac between the crop and the gizzard, belongs evidently to the ostrich type, characterized by massive size, absence of wings, strength of lower extremities, flattened breast bone, and hairy nature of the feathers.

CASTALIA, a fountain at the foot of Mount Parnassus, near the temple of Apollo, at Delphi, in Phocis. It was, like the mountain, sacred to Apollo and the muses, which were therefore called Castalides. The Pythia used to bathe in its waters before delivering the ora-

cles of the god; it was regarded as a source of inspiration for poets, and had its name, according to some authorities, from Castalia, the daughter of Achelous, who, being pursued by Apollo, threw herself into the fountain.

CASTALIO, or **Castalion**, **Sébastien**, a French theologian, born in Dauphiny in 1515, died in Basel, Dec. 20, 1563. His family name was Châteillon, which he latinized into Castalion. Through the influence of Calvin he was made professor of classical literature at Geneva. Having quarrelled with Calvin, who caused his banishment in 1544, he repaired to Basel, where he taught Greek; but as his stipend did not suffice to support his numerous family, he was compelled to employ part of his time in agricultural labors. Besides several theological works, he made a Latin translation of the Bible, the best edition of which is in folio (Basel, 1573). He defended the right of free discussion in a collection of maxims compiled from various sources.

CASTAÑOS, **Francisco Xavier de**, duke of Baylen, a Spanish general, born in Madrid about 1755, died there, Sept. 24, 1852. In early life he was sent with Gen. O'Reilly to the court of Frederick the Great to study the art of war, and on his return to Spain he entered the army. When Napoleon invaded Spain, Castaños was appointed captain general of the Spanish armies in Andalusia. At Baylen, July 19, 1808, he encountered a French force under Dupont, who were surrounded and after some fighting forced to capitulate on the 22d, surrendering 18,000 men. He was shortly after routed by Lannes at Tudela (Nov. 23, 1808), and resigning his command became a member of the regency. In 1811 he was appointed to the command in Estremadura and Galicia, in 1812 was placed by Wellington in charge of the fortress of Ciudad Rodrigo, and early in 1813 was given the command of one of the four armies into which the Spanish forces were then divided. He contributed to Wellington's victory at Victoria, but at the close of the year he was removed by the new regency, under the pretext that he was needed in the council of state. After the restoration he was made captain general of Catalonia, an appointment which he resigned in 1816, but again accepted in 1823. In 1815 he was placed at the head of a force of 80,000 men destined to invade France, in 1833 received the title of duke of Baylen, and after Espartero's fall in 1843 became for a time the guardian of Queen Isabella. He became a senator in 1845.

CASTE. See **INDIA**.

CASTELAR, **Emilio**, a Spanish statesman, born in Cadiz, Sept. 8, 1832. His father, an exchange broker at Alicante, and afterward at Cadiz, spent seven years in the English possessions, chiefly in Gibraltar, to escape from the sentence of death passed on him for his implication in liberal movements. He died in Madrid in 1839, leaving his family almost destitute. Emilio nevertheless received a supe-

rior education. He early published novels, and subsequently became known as a democratic journalist and orator. In December, 1856, he was the successful competitor for the chair of history and philosophy in the university of Madrid, delivering at the same time lectures on the history of civilization in the Athenæum. He was deprived of his position in 1864, after having founded with Carrascon the journal *La Democracia*. This was suppressed in 1866, owing to his participation in the disturbances of June 22, when he was sentenced to death, but escaped in disguise to Switzerland and thence to France. When the revolution of September, 1868, began, he returned to Spain and was restored to his professorship. He kindled the enthusiasm of the people by his eloquent appeals in favor of democracy, and was elected to the cortes for Saragossa and Lérida. In this body he opposed Prim and Serrano, and subsequently King Amadeus, and became the most popular leader of the republican party. In 1873 he actively promoted the declaration of the republic, and was chosen minister of foreign affairs Feb. 12, and president of Spain Sept. 7, with extraordinary powers. He has published *Discursos parlamentarios* (3 vols., Madrid, 1871), and *Recuerdos de Italia* (translated by Mrs. Arthur Arnold, "Old Rome and New Italy," London, 1873).

CASTEL BRANCO, or **Castello Branco**, a city of Portugal, in the province of Beira, situated on the Liria, 42 m. N. E. of Abrantes; pop. 6,700. It is the see of a bishop, and has a college, two collegiate churches, and a ruined castle on the summit of the hill on which the town stands.

CASTEL-FIDARDO, a town of Italy, in the province and 11 m. S. of Ancona, near Loreto, on a range of hills between the Musone and the Aspio; pop. about 6,500. Near it the Italians under Gen. Cialdini defeated the papal troops under Lamoricière, Sept. 18, 1860.

CASTEL-FRANCO, a town of Italy, in the province of Treviso, 23 m. N. W. of Venice; pop. about 5,000. Here the French, on Nov. 23, 1805, gained a victory over the Austrians.

CASTELLAMARE, or **Castel a Mare**. **I.** A seaport of S. Italy, in the province and 17 m. S. E. of Naples, with which it is connected by railway; pop. in 1872, 26,381. It is situated on the lower slopes of the Monte d'Auro, along a sheltered beach, and commands an extensive view of the bay of Naples from Vesuvius to Miseno. It is defended by two forts, and contains a royal palace, a cathedral, five churches, several convents, manufactories of linen, silk, and cotton cloth, 12 thermal and mineral springs, and a national dockyard. It has acquired celebrity also as a summer resort, in consequence of the salubrity of its air and the beauty of its environs. It is built near the site of the ancient Stabiae, which, having been destroyed by Sulla during the civil wars, was afterward occupied principally by villas and pleasure grounds. It was here that the elder Pliny, wishing to approach as near as possible

to Vesuvius during the eruption which overwhelmed Herculaneum and Pompeii, met his death, A. D. 79. **II.** A seaport of Sicily, in the province of Trapani, 4 m. N. W. of Alcamo;

Castellamare di Stabia.

pop. about 9,000. The bay is spacious, but not safe during northerly winds. It exports wine, fruit, grain, manna, and opium.

CASTELLANETA, a town of S. Italy, in the province of Lecce, 18 m. N. W. of Taranto; pop. about 6,500. It is the seat of a bishop.

CASTELLI, Ignaz Friedrich, a German dramatist, born in Vienna, May 6, 1781, died near Lillienfeld, Feb. 5, 1862. He was educated for the law, but devoted himself to composing patriotic songs for the Austrian army, and preparing pieces for the stage. His songs having given umbrage to Napoleon, he fled to Hungary. In 1814 he accompanied Count Cavriani as secretary to Paris, and afterward he served in the same capacity in Italy. In 1840 he retired with a pension and the office of state librarian. He was the author of many poems, popular songs, and miscellaneous writings, and was at various times connected with the press of Vienna, but is best known by his productions for the stage. More than 100 plays, partly adapted from the French, partly original, are attributed to him. In 1848, 100,000 copies of his political pamphlets in favor of the revolution were sold. His autobiography was published in 1861-'2, in 3 vols.

CASTELLON DE LA PLANA. I. An E. province of Spain, bordering on the Mediterranean, forming part of the ancient kingdom of Valencia; area, 2,446 sq. m.; pop. in 1867 (estimated), 288,921. It is very mountainous, and is watered by several small rivers, the most important of which are the Mijares and Palencia. It is well cultivated, produces grain, and has many mines and mineral springs. The chief towns, besides the capital, are Benicarlo, Villareal, and Burriana. **II.** A city, capital of the province, situated in a fertile region, 4 m. from the sea, and 38 m. N. by E. of Va-

lencia; pop. about 20,000. It has linen and sail-cloth factories, and carries on considerable trade in hemp. The former diocese of Castellon de la Plana is now united with Segorbe. An aqueduct, cut in great part through the limestone rock, brings the water from the Mijares, which is about 5 m. distant, into the plain in which the town is situated.

CASTELNAU, Michel de, sieur de la Mauvissière, a French soldier and diplomatist, born at Mauvissière about 1520, died at Joinville in 1592. He entered the army in 1547, and won the favor of Francis of Lorraine, grand prior of France, under whom he afterward served in the navy, and who on becoming lieutenant general of the kingdom (1557) employed him in diplomatic missions to Scotland, England, Germany, the Netherlands, Savoy, and Rome. He negotiated a treaty with Queen Elizabeth, and dissuaded her from insisting on the restoration of Calais. In 1560, after the death of Francis II., he accompanied Queen Mary to Scotland, and for a year rendered her efficient service in the field and in council. He distinguished himself in the civil war, negotiated a favorable treaty of peace with England, and was made governor of St. Dizier. He was again employed in various missions, was ambassador to England from 1574 to 1584, and on his return declared against the league. Henry IV. upon his accession treated him with great favor. His memoirs, written in England, extend over the period from 1559 to 1570, and are a valuable record of the events of the time. They were published in 1621, and are to be found in Petitot's *Mémoires relatifs à l'histoire de France*. He translated the Latin work of Ramus on the ancient Gauls. His life, by Le Laboureur, was published in Paris in 1659.

CASTELNAUDARY, a town of France, in the department of Aude, on the canal of Languedoc, 30 m. S. E. of Toulouse; pop. in 1866, 9,073. The reservoir of St. Ferriol forms a harbor, and an active trade is carried on in cereals, wine, fruit, cloth, linen, silk, cotton yarn, leather, and other articles. According to some authorities, the ancient Sostomagus was situated near Castelnaudary, the modern name being a corruption of *Castrum Novum Arianorum*, as the new town was called after the old one had been destroyed in the 5th century. It became the fortified capital of the county of Lauragais, ruled by the counts of Toulouse. It suffered severely during the crusade against the Albigenses, and in 1211 was the scene of a battle between Raymond of Toulouse and Simon de Montfort, the former of whom destroyed the fortifications in 1229. In 1237 an *auto da fê* was enacted here, in which many persons accused of heresy were put to death. It was burned in 1355 by Edward the Black Prince, but was rebuilt in 1366. In September, 1632, the duke of Montmorency, commanding the forces of Gaston of Orleans, was defeated here by the royal force under Marshal Schomberg, wounded, taken prisoner, and executed.

CASTELSARRASIN, a town of France, in the department of Tarn-et-Garonne, 35 m. N. W. of Toulouse; pop. in 1866, 6,838. It has factories of hats, woollen goods, linen, and hosiery, and a large oil and saffron trade.

CASTEL-VETRANO, a town of Sicily, in the province of Trapani, situated on a hill 6. m. from the sea, 45 m. S. W. of Palermo; pop. in 1872, 20,420. The town is well built, and has a considerable trade in wine and olives.

CASTI, Giovanni Battista, an Italian poet, born at Prato, Tuscany, in 1721, died in Paris, Feb. 6, 1803. He was for some time professor in the seminary of Montefiascone, and afterward obtained a canonry in the cathedral there. Having gained the favor of Joseph II. of Austria, he spent several years as unpaid attaché to foreign embassies, and at the death of Metastasio in 1782 he received the appointment of poet laureate at the court of Vienna; but he relinquished this office after the death of the emperor Joseph, and spent the last years of his life in Paris. In early life he had written 18 poetical tales, and afterward added 30 more, making altogether 48, published in Paris in 1804, under the title of *Novelle galanti*, all loose. His fame depends on a political satirical poem, *Gli animali parlanti* (Paris, 1802). It has been translated into French and Spanish, and there is an abridged English version. He also produced several burlesque operas.

CASTIGLIONE. I. A village of Italy, near the lake of Gabii, 10 m. E. of Rome. It occupies the site of the ancient city of Gabii, and is rich in remains of antiquity. Old walls, portions of a temple of Juno, a Grecian theatre, and an aqueduct are among its most interesting ruins. **II.** A village of Italy, on the Stiviere, near the Lago di Garda, 16 m. S. E. of Brescia. The vanguard of the Austrian army under Wurmser was defeated here, Aug. 3, 1796, by the French under Augereau, and the main body two days later by Gen. Bonaparte. The battle of Solferino, June 24, 1859, was fought almost on the same ground.

CASTIGLIONE, Baldassare, an Italian statesman and author, born at Casatico, near Mantua, Dec. 6, 1478, died at Toledo, Spain, Feb. 2, 1529. His career commenced in the military service of the duke of Milan, but he is better known as a diplomatist, in which capacity he was intrusted by the dukes of Urbino with important missions to Henry VII. of England, Louis XII. of France, and Pope Leo X. He became a favorite of this pontiff, and was regarded as one of the ornaments of his court. Clement VII. subsequently sent him as nuncio to Madrid, but shortly after his arrival Rome was sacked by the imperialists under the constable de Bourbon. It was not possible for Castiglione to have foreseen or prevented this catastrophe, but the reproaches of those who insinuated that he had been neglectful of the interests of his country preyed upon his mind and hastened his end. He was universally lamented, and the emperor Charles V., in an-

nouncing his death, exclaimed, "One of the truest gentlemen in Christendom is dead." Castiglione was not a voluminous writer, but his published works are models of composition. His work on court life, entitled *Il libro del cortegiano*, was first printed by Aldus in 1528, and a version was published in London in 1727. He also published Italian and Latin poems and two volumes of letters.

CASTIGLIONE, Carlo Ottavio, count, an Italian philologist and antiquary, born in Milan in 1784, died in Genoa, April 10, 1849. In 1819 he published a description of the Cufic coins in the cabinet of Brera at Milan. His principal work in oriental literature, *Mémoire géographique et numismatique sur la partie orientale de la Barbarie appelée Afrikia par les Arabes* (Milan, 1826), is an effort to ascertain the origin and history of the towns in Barbary whose names appear on Arabic coins. In conjunction with Angelo Mai, he published an edition of Uphilas's Gothic translation of St. Paul's Epistles, which Mai had discovered among the palimpsests of the Ambrosian library. Most of the dissertations which enrich the work, the publication of which extended through 20 years, were written by Castiglione.

CASTIGLIONE, Giovanni Benedetto, called IL GRECHETTO, a Genoese painter and engraver, born in Genoa in 1616, died in Mantua in 1670. He was a pupil of Paggi and of Ferrari, and according to some of Vandyke, and gained a high reputation as a historical, landscape, and portrait painter, and also as an engraver. His specialty, however, was animal painting. Many of his pictures are in the museum at Florence, and in the Louvre at Paris; and some have found their way to Venice, Milan, Munich, and Dresden.

CASTIGLIONE, Giuseppe, an Italian artist and missionary, born in 1698, died in Peking in 1768. He was thoroughly instructed in the art of painting, but joining the order of the Jesuits, Peking was assigned as the field of his labors, and there he passed the greater part of his life, in favor with several successive emperors. He made his art an accessory to his religious labors, and the emperor Kien-Long erected several palaces from designs furnished by him. He is said to have frequently exerted his influence to protect Christians from persecution.

CASTILE (Span. *Castilla*), so called from the number of its castles). **I.** An ancient kingdom of Spain, situated in the centre of the peninsula, and the source and chief seat of the Spanish nation. It is divided into Old and New Castile. Old Castile was the northern part, which first shook off the yoke of the Moorish conquerors, while New Castile was so called because it was a later acquisition. The Castiles occupy a large portion of the great central plateau, and their area of 45,000 square miles is about one fourth of that of all Spain. The people, about 3,000,000 in number, are a fine race, the heart of the Spanish nation as they are proverbially called—proud, manly, brave, and

self-respecting. Castile was perhaps never entirely subjugated by the Moors, and became fully independent after the middle of the 8th century, being ruled by counts. It was erected into a kingdom in 1033, when Ferdinand, son of Sancho III., king of Navarre, was made king. Upon the death of Bermudo III., king of Leon, in 1037, that kingdom was united to Castile. The two crowns of Castile and Leon were afterward separated and again united several times, until in 1479, Ferdinand II. of Aragon having married Isabella, queen of Castile and Leon, the three kingdoms were united into one. (See SPAIN.) **II. Old**, the northern division of Castile, bounded N. by the bay of Biscay and the Basque provinces, E. by Navarre and Aragon, S. by New Castile, and W. by Leon and Asturias; area, 25,409 sq. m.; pop. in 1867, 1,716,193. It is of very irregular shape, stretching from S. W. to N. E. In the north the Cantabrian range of mountains runs across the province. On the south it is divided from New Castile by the Sierra de Guadarrama, the Somosierra, and a continuing chain, which under different names forms also the E. boundary. The rivers are the Duero (Douro) in its upper course, its affluent the Pisuerga in the centre, and the Ebro on the north. There are numerous minor streams: the Riaza, Cega, Piron, Eresma, and Adaja, tributaries of the Duero; the Oca, Tiron, and Oja, affluents of the Ebro. These are torrents after rains, but in summer many of them are insignificant. The climate is dry and hot in the summer, dry and cold in the winter. The plains are almost deserts, whose vegetation affords but a scanty pasturage, and disappears entirely under the summer sun. On the sea-coast, and in the mountains, valleys, and hill slopes, nature is much less sterile. Old Castile includes the provinces of Ávila, Burgos, Logroño, Palencia, Santander, Segovia, Soria, and Valladolid. The general occupation of the people in the interior is agriculture and grazing. In the towns some inferior manufactures, chiefly of coarse woollens, cotton, linen, leather, and glass, are carried on. Sheep and cattle are reared in large numbers and exported. Wheat and corn are also exported, and wines and fruits are produced in abundance. **III. New**, the southern division, bounded N. W. and N. by Old Castile, E. by Aragon and Valencia, S. by La Mancha, and W. by Estremadura; area, 20,178 sq. m.; pop. in 1867, 1,289,415. It is divided into the provinces of Madrid, Toledo, Guadalajara, and Cuenca. The principal rivers are the Tagus and its tributaries, the Tajuña, Henares, Jarama, Guadarrama, and Guadiela, and the Júcar, which falls into the Mediterranean, and its tributaries, the Guadazaon and Cabriel. The climate is the same as that of Old Castile. Large crops of wheat are raised, and the mountain slopes afford abundant pasturage. The vine is cultivated, and olives and oil, saffron, honey, and hemp are produced in considerable quantities.

Woollens, paper, linen, cotton, and silk are manufactured.

CASTILLA, Don Ramon, a Peruvian general, born at Tarapacá, Aug. 30, 1797, died May 25, 1867. He entered the Spanish army in 1816, and was made lieutenant in 1820. Soon afterward he joined the army of independence, and was made lieutenant colonel. In 1830 he went to Lima, and was appointed by Gamarra chief of staff of the whole army. He was made brigadier general by Orbegoso, the provisional president, whom he supported until the treaty with Santa Cruz, the president of Bolivia. He then fled to Chili, and in 1837 joined the army of the Peruvian patriots who marched against Santa Cruz. Castilla was second leader of the vanguard at the attack upon Lima and defeat of Orbegoso, and made common cause with Gamarra, who was proclaimed president by the patriots, while Castilla was appointed minister of war. In 1841 he was second in command of the Peruvian army which invaded Bolivia. In 1844 he overthrew the dictator Vivanco, and in the following year he was elected president of Peru. At the expiration of his term of office in 1851 he was succeeded by Gen. Echenique. Soon after, the administration of the latter having become unpopular, Castilla began a revolution at Arequipa, overcame Echenique, and entered Lima in 1855 as supreme ruler of the country. In this capacity he made many reforms, the most important of which was the abolition of slavery. He was reelected president in 1858, and two years afterward proclaimed a new constitution, which established universal suffrage and prohibited the exercise of every form of religion except the Catholic. In 1861 he made an unsuccessful attempt to annex Bolivia to Peru. In 1862 he was succeeded as president by Gen. San Ramon, and he in 1863 by Pezet. Castilla, having assumed a hostile attitude toward the latter, was arrested in 1865, but soon gained his liberty, and joined the movement under Prado. In 1867 he headed an insurrection against Prado, and was on his way to Arica when he died.

CASTILLEJO, Cristóval de, a Spanish poet, born at Ciudad Rodrigo toward the close of the 15th century, died in Vienna probably in 1556. Attached from the age of 15 to Ferdinand, the younger brother of Charles V., and afterward emperor of Germany, he subsequently officiated as secretary to that prince. He was a zealous champion of the old Spanish poets, and a decided opponent of the new Italian school. One of his most fanciful and characteristic poems is entitled "Transformation of a Drunkard into a Mosquito." His poetry, though circulated in manuscript, was forbidden by the inquisition, but a selection was permitted to be printed in 1573. His works were published in Antwerp in 1598, in Madrid in 1600, and reprinted in Fernandez's "Collection of Spanish Poets," 1792.

CASTILLO, Diego Enriquez de, a Spanish chronicler of the 15th century, born at Segovia. His

annals of the reign of Henry IV. of Castile, from 1454 to 1474, were published by José Miguel de Flores (Madrid, 1787). He also composed a poem relating to the death of Alfonso V. of Aragon, published by Ochoa (Paris, 1844), in the same volume with the inedited poems of the marquis of Santillana. Castillo is said to have fallen into the hands of Henry's younger brother Alfonso, the pretender to the throne, after the battle of Olmedo; but little is known about his career, except that he was employed in important missions.

CASTINE, a town and port of entry of Hancock co., Maine, on the E. bank of the Penobscot, 34 m. below Bangor; pop. in 1870, 1,303. It derives its name from the baron de Castine, a French nobleman, by whom it was settled in 1667, in company with a French colony, who afterward abandoned it in consequence of border wars with the Indians and English colonists. In 1760 it was settled by the English. It is situated on a peninsula, enclosing a spacious harbor always accessible to vessels of the largest class. Its inhabitants are chiefly engaged in ship building and fishing. For the year ending June 30, 1871, there were belonging to the port 347 vessels, of 23,997 tons; employed in the cod and mackerel fishery 148, of 6,100 tons; built 15, of 1,561 tons. It has a state normal school and three churches.

CASTING, the forming of metals and other substances by pouring them in a melted or liquid state into moulds, and allowing them to solidify by setting or cooling. The term when applied to the casting of metals is used synonymously with founding, and the place where the work is done is called a foundery.—The origin of the casting of metals cannot be traced; it was performed in the earliest times, and from the vestiges discovered seems to have been at first confined to ornamental articles, such as statues, medals, and parts of household furniture. The metal chiefly used by the ancients was bronze, and it is an interesting fact that their alloy contained about the same proportions of tin and copper as that which is used at the present time. Most of the bronze castings which have been discovered in excavations at Nineveh have been found, when analyzed, to contain about 10 per cent. of tin, the proportion now in use for the best quality of statuary bronze. Bronze castings have been found in Egypt which are thought to be 4,000 years old. A cylinder with the name of Pepi, of the sixth dynasty, and other bronze implements of the same age, all of which date more than 2,000 years before the Christian era, bear evidence of having been cast in moulds. It is related in the book of Deuteronomy that Og, king of Bashan, had a bedstead of iron, but whether wrought or cast is unknown. The earliest method of working iron was probably like that still in use in India and some other countries. The broken ore was mixed with charcoal and subjected by heat to deoxidation. The semi-plastic mass resulting from this treat-

ment was then hammered into a bloom, and this reheated and hammered until malleable iron was produced. It is probable that the metal was a long time used in this way before the melting and casting of it was practised. The account given of the molten calf which Aaron caused to be made of the ornaments brought to him, shows that the art of casting was brought by the Israelites from Egypt. From the description given of the articles made for Solomon's temple by the Tyrian master Hiram (1 Kings, vii.) there can be no doubt that many of them were cast: "For he cast (formed) two pillars of brass, of eighteen cubits high apiece." "And he made two chapiters of molten brass, to set upon the tops of the pillars." "In the plain of Jordan did the king cast them, in the clay ground between Succoth and Zarthan." There is here not only evidence of the casting of bronze (for that is what is meant by "brass"), but also of the material used in making the moulds, which was the same as that used at the present day, namely, loam, and which composes the soil at the place where Hiram built his furnace. The bronze castings of the Assyrians were remarkably good, particularly those of animals, as is shown by the figure of a lion found by M.

FIG. 1.—Bronze Lion from Nineveh.

Botta in the excavations in the palace of Khor-sabad. This little statue is thought to have been cast in a single piece. That it is a work of Assyrian art is shown by the cuneiform characters that were found upon it. How long before the fall of Nineveh it was cast cannot be told, but it is probable that some of the bronzes found there are older than the temple of Solomon. In Babylon bronze statuettes have been found. We are told by Herodotus that both the town and palace gates were of this material; and it would seem from the accounts of Diodorus Siculus that they were so massive that they were not opened in the ordinary manner, but by a machine. Rawlinson assumes that they were cast. Fine works of Grecian art were made in embossed bronze as early as the 7th century B. C., but, according to historians, it was not till that or the following century that Rhœcus and Theodorus introduced bronze castings into Greece, and they

are sometimes spoken of as the inventors of this art. It is difficult to believe that it was not introduced there at an earlier period, when it is certain that it was practised at Tyre, distant but a few hundred miles by water, 400 years previously. However that may be, from the time of Theodorus it was carried to greater and greater perfection, until the time of Lysippus and Praxiteles, when bronze was moulded into forms of transcendent beauty. It is not unjust to assume that the world owes as much of its knowledge of casting metals to the old Greek sculptors as to any other source. The new art introduced by Rhœcus and Theodorus was transmitted to Crete, where two artists, Dipœnes and Scyllis, were distinguished as sculptors in bronze as well as marble. They carried the art to Sparta, which afterward produced many artists of her own, among whom was Gitiadas, also celebrated as an architect, and who is said to have built the temple of Minerva Chalceœus at Sparta, and cast a bronze statue of the goddess. The colossal statue of Apollo at Rhodes, made by the sculptor Chares, a pupil of Lysippus, who flourished about 290 B. C., may be mentioned as an example of the magnitude to which the ancient Greeks were able to carry their works. This bronze statue was more than 105 ft. high, and, like modern statues, must have been cast in several pieces, which were afterward fastened together. The fragments into which it fell when destroyed by an earthquake 56 years after its erection lay on the ground 923 years, when they were sold by the Saracens to a Jew of Emesa, who loaded 900 camels with them. A fine example of bronze casting in the spirit of Lysippus is the beautiful statue of Mercury discovered at Herculaneum, and now in the

FIG. 2.—Bronze Statue of Mercury.

museum at Naples. Whether it was cast in Italy or brought from Greece is uncertain. Church bells are said to have been introduced by Paulinus, bishop of Nola in Campania,

about the year 400. They were probably introduced into England about the close of the 7th century. The great bell at Peking, cast in the reign of Yung-loh in the beginning of the 15th century, occupies a noteworthy place in the history of casting. It is 14½ ft. in height and 13 in diameter, and is estimated to weigh about 112,000 lbs. It is covered both within and without with perfectly formed Chinese characters, embracing 87 sections of the sacred books of one of the religious orders. The greatest feat, however, that was ever performed in bell founding was the casting of the great bell of Moscow, which occurred in 1733 in the reign of the empress Anna. It is 19 ft. 3 in. in height and 60 ft. 9 in. in circumference, and weighs 443,772 lbs. The appliances for melting this great mass of over 200 tons of bronze metal must have been stupendous, and have required technical knowledge of no mean order.

—The process of casting varies with the kind of article to be produced and the material of which it is made. In casting a statue or a bust of plaster of Paris, where perfection of exterior form is alone sought, it is only necessary to pour an indefinite quantity of the fluid mixture of plaster and water into a hollow mould and take an impression of its internal surface. In casting a medallion or cameo it suffices to pour the liquid material over a one-sided, open mould to such a depth as may be required. But in the casting of statues in bronze, or in the casting of bells, of stoves, of cylinders, and of pieces of machinery, and all other articles that are required to have a definite thickness and weight, it is necessary that the moulds shall have two or more walls. The casting of statuary in plaster of Paris and in bronze will be treated of at the end of this article.—Casting or founding may be divided into: 1, preparing a mould of the figure to be cast, which process usually includes the making of a pattern of such figure; 2, the melting and reducing to the proper degree of fluidity of the metal; and 3, the introduction of the molten metal into the cavity of the mould, and whatever manipulation may be necessary during the solidification and cooling. The mould may be made of metal, of stone, of plaster of Paris, of clay, of loam, or of sand. A metal mould may be formed either by excavating it with tools worked in a lathe or by the hand, or it may be cast in a similar manner to the article of which it is to form the mould. Small articles of the more fusible metals, and of simple form, are usually cast in metal moulds which are composed of two or more parts held together by hinges or pins. In using a metal mould, the molten metal, after being poured into it, may be allowed to solidify while cooling by the molecular attraction of its particles alone, or it may be so constructed that its contents are subjected to pressure during solidification. Bullets and small shot and printing types are examples of casting in metal moulds. Ingots of brass are examples of casting in stone

moulds, which are usually of granite. Easily fusible metals are sometimes cast in moulds of plaster of Paris, which possesses some advantages as a mould material in consequence of the ease with which it may be given various forms, and their great permanency under favorable circumstances. Those metals, however, which have high melting points cannot conveniently be cast in plaster moulds, because this substance readily crumbles when subjected to a heat above 400° F.—Before describing the casting of metals in sand and loam moulds, a brief description of the establishment where the work is performed is desirable. A well appointed foundry, in addition to the room required for the actual work of moulding and casting, should have rooms for storing and preparing

the materials of the moulds, such as grinding and sifting the sand, loam, sea coal, coke, plumbago, or charcoal. There should also be a workshop for making the patterns which are to be used in the formation of the moulds. The moulding room embraces an area of greater or less extent, but even in moderate establishments it is necessarily of considerable size. Where heavy articles are founded there are huge cranes for lifting and moving moulds and castings from one place to another. The floors of such foundries are also covered or rather filled with moulding sand to a considerable depth, varying from 5 to 10 ft. Fig. 3 represents the interior of a foundry for heavy castings. In one part of the room, usually at one side, and sometimes adjoining another room

Fig. 3.—Interior of Iron Foundry. *a, a*. Cupola furnaces. *b, b*. Tuyeres. *c*. Crane. *d, d*. Ovens for baking moulds. *e*. Cope of a greensand mould, made in the floor bed. *f, f*. Temporary furnaces for forcing heat through the pipes *g, g* into a large mould. *h*. Mould of a steam cylinder, placed in a pit and in process of completion.

for making light castings, stands the furnace for melting the metal. This may be an air furnace, or that form of a blast furnace known as the cupola, which is most in use at the present time. Anthracite coal is used for fuel to a great extent in this country, but coke is better, and wood charcoal the best, on account of containing no sulphur. Unlike the air furnace, which depends upon the ascending column of air in the chimney for its draught, it is fed by a current of air forced in at the bottom through tubes called tuyeres by a blowing machine. The cupola is usually made of boiler iron in the form of a cylinder or cylindroid, lined with fire brick. It is from 10 to 16 ft. in height and from 3 to 6 ft. in diameter inside, and capable of melting from 5 to 15 tons of metal per hour. The chimney may be of brick, or of boiler iron lined with fire brick, which is more common. A cupola is often spoken of as holding a charge of so many tons of metal; but as only a limited

quantity of molten metal can be contained in it at one time, because it must be confined to the space below the tuyeres, its capacity is more correctly measured by the amount of metal it will melt in a given time. For a fuller description of its construction, see FURNACE. A sufficient explanation will be found in fig. 4 to enable the reader to understand the manipulations connected with the process of casting. The tuyeres, *a, a*, are seen to enter the cupola from 10 to 16 inches above its floor. The space just above the tuyeres has the shape of an inverted cone, which has the effect to hold the contents in such a relation to the blast as is best calculated to make it the most effectual. The floor of the cupola, *b*, when in use is composed of sand 6 or 8 inches in depth, lying upon the bottom plate *c*, which rests upon supports, and may be dumped by their removal. Some cupolas are chambered at the lower section, the blast entering through a row

FIG. 4.—Perpendicular Section of Cupola.

of holes in the inner wall. In the upper part of the back of the cupola is the door for receiving the charges. Fig. 5 shows the exterior of the lower part of a cupola. A cupola is charged by placing a sufficient quantity of kindling wood upon the floor, and above this a layer of the best anthracite coal in large lumps, and in sufficient quantity to fill the cupola to the height of

FIG. 5.—Lower Part of Cupola. *a, a.* Tuyeres. *b, b.* Small isinglass windows for showing the state of combustion and position of the layer of coal. *c.* Pot for receiving the melted metal. *d, d.* Columns of support. (The smaller upright rods support the movable floor, and stand in the pit below the cupola.)

several inches above the entrance of the tuyeres after it has well settled and the wood has burned away. This precaution must be carefully observed, because if the charge of iron above the coal should come down to a level with the entrance of the blast, combus-

tion would be checked, the metal become chilled, the process stopped, and the dumping of the charge necessitated. Upon the layer of coal thus carefully deposited, one of pig iron is placed, varying in quantity from 1,000 to 5,000 lbs., according to the size of the cupola and to the rapidity with which it is proposed to effect the melting; and upon this another layer of coal is deposited, and afterward succeeding layers of iron and coal. Fluxes are added where occasion requires, according to the judgment of the founder, pounded marble or limestone being most frequently employed. The wood is usually ignited when the first layer of coal is deposited, and in from an hour to an hour and a half the furnace may be tapped. It usually requires about 1 lb. of coal to melt 6 lbs. of iron. There is a wide difference in the processes of making heavy and light castings. A description of the latter, which is the simpler, will be given first. The first matter to receive attention is the selection and proper treatment of the sand, which is the material used for making the moulds of light castings; and it is one of the utmost importance, for it is only by the use of sand possessing certain properties that the formation and retention of a smooth and well defined cavity can be produced, having at the same time sufficient porosity to allow of the escape of air and gases which are generated during the pouring of the metal. If the sand is too dry, it will not admit of the formation of a defined cavity within it. It must possess in a certain degree the nature of a plastic or adhesive substance. Pure sand cannot therefore be used for a mould, and the best material with which it can be mixed is clay, but not to an extent to form what might be called a loam. Enough moisture must also be present to produce a proper degree of adhesion, but the quantity must be as small as possible, for too much would produce an amount of vapor when the molten metal is poured in that would injure or destroy the mould, or cause the surface of the sand to adhere to it on its removal. A fine sand which is slightly loamy is therefore selected, and this is not found in every locality where common sand exists, but has often to be transported considerable distances. The moulding sand which is used in New York city is principally obtained in New Jersey, in the vicinity of Troy and Albany, and from some parts of Long Island; but the cost of sand is not an item of much consequence after the first supply is obtained, as it is used over and over many times. That which is used in some parts of the mould is mixed with finely pulverized bituminous coal, coke, or plumbago, as the circumstances may demand; and these substances are frequently spread upon the surface of the mould, to effect various purposes, as will be explained further on. An apparatus called a flask contains the sand in which the mould is made. It is composed of three or more parts, a bottom board, a drag, a cope, and upon occasion one or more

checks. A wooden flask, containing one check and having the parts fastened together by clamps, is represented in fig. 6. The drag as

Fig. 6.—Moulding Flask.

well as the checks is a rectangular frame made of plank, similar to the four sides of a box without top or bottom. The cope is similarly constructed, but having in addition

one or more bars running across it, of variable depth, to suit the shape of the mould, and into which nails are driven to assist in holding the sand in place. Fig. 7 represents the construction of a wooden cope.

Fig. 7.—Cope.

Iron flasks have the same general construction, with the addition of strong ears by which they may be lifted with a crane. It is upon the proper construction and management of the flask, and the nice and exact mixing and tempering of the moulding sand, that much of the success in casting depends. Indeed, the founder regards his work as chiefly accomplished when the mould is fairly dressed and faced, and proper avenues have been provided for pouring and for the escape of air and gases, and the cope is readjusted to its place in such a manner that no part of the surface of the mould is disturbed. In making a flask mould, the moulder first lays upon the floor what is called a turn-over board, and upon this places the pattern. If this is of such a form that it will not lie firmly, or if it is liable to be bent or broken by packing of the sand upon it, it must be supported by a bed piece. Facing sand, which is prepared by mixing fine dry sand with the ground scrapings from the surface of previous castings, is then sifted over it, and the drag is laid upon the turn-over board. Sand is then thrown in, covering the pattern to a certain depth, and packed with the hand. More is then thrown in, perhaps enough to fill the drag, and then

Fig. 8.—
Rammer.

the moulder treads it down evenly with his feet, when, taking a rammer (see fig. 8), and using the end containing the pin, he proceeds to pack it firmly all round the sides of the drag. Then, using the butt end, he rams the sand firmly all over the mould. After the drag, and whatever checks may be used, are filled, the bottom board is placed over it and clamped or keyed to the turn-over board. The pattern is thus enclosed in a box, and lying upon its bottom, covered with sand. The drag is then turned over, bringing the bottom board to the bottom, and the pattern to the top. The clamps are then removed and the turn-over board is taken off, leaving one side of the pattern uncovered. With a parting trowel (a small thin-

bladed tool, similar in form to a bricklayer's trowel), a joint or parting is made by scraping away some of the sand from about the pattern, and especially to the furthest lateral lines, so that it may be drawn without injury to the mould. The surface of the sand is then smoothly dressed, and parting sand is sifted from a bag over its surface as well as that of the pattern, and the superfluous particles are blown away by a bellows. Pieces of wood, some cylindrical and some flat, are next placed upright on the surface, to form holes for pouring and for the escape of air, which is effected by their removal on the completion of the mould. The air holes are sometimes made with a pin, and are above the cavity; the pouring holes are usually at the sides, and connected by horizontal channels. Fine moulding sand is now sifted over to a sufficient depth to insure a smooth surface, and the cope is adjusted and clamped.

(See fig. 9.) More sand is then thrown in between the bars and tucked under them with the hands and well packed upon the pattern. Still more sand is again added and well packed with the rammer, and this process is repeated until the proper depth is attained. The pieces for forming the holes are now taken out, the clamps are removed, and the cope is lifted off to one side, or, if furnished with hinges, may be turned back upon them in the manner of a trunk cover (fig. 10). The pattern is then carefully lifted out of its bed, and if any corners or edges have been knocked off, or any other injury has been done, it is repaired with a trowel or some suitable tool. Pulverized

Fig. 9.

Fig. 10.—Drag and Cope, opened.

plumbago or charcoal is then dusted over the surface; and if fine work is required, the pattern is replaced and carefully pressed down to give as much perfection to the impression as possible. This operation is technically called printing. The pattern is then gently tapped with the handle of a tool, to loosen it, and gently raised with the fingers or some appropriate instrument, or by means of a screw inserted into a hole previously prepared. Channels are now cut in the surface leading from the points upon which the pieces for forming pouring holes stood to some part of the mould. The pieces still remaining in the cope are now removed and the holes are dressed. All particles of loose sand are then blown from the

surfaces of both parts of the mould, and the cope is gently replaced and secured with keys or clamps. The relation of the parts as they now exist is represented in section in fig. 11.

FIG. 11.—Section of Mould.

All that now remains to be done is to melt the metal and pour it into the mould; a critical operation, requiring much care, and not safely performed except by experienced moulders. The pouring is done from iron pots lined with clay, called ladles. They are of various forms and sizes, to suit the work to be done. Some have one handle, and are intended to be carried by one man. Others have the form represented in fig. 5, but with longer handles, capable of holding from 200 to 300 lbs., and are carried by two or more men. When the moulds are ready the furnace is charged in the manner already described, and one of the large carrying pots is placed under the spout. The melting point of cast iron varies somewhat, owing to its freedom from other metals and the quantity of carbon which it contains. Hard, gray cast iron melts at about 2,900° F. Scotch pig melts at a lower temperature than many other kinds, because of its large quantity of carbon. The best American iron is harder, contains less carbon, and requires more heat to melt it. It is a common practice among foundries to melt different brands of iron together to give the mixture desired characteristics which they do not possess separately. The practice varies at different establishments, each founder having his own favorite formulas. When a sufficient quantity of metal in the cupola has attained the proper degree of fluidity, the clay stopper or plug is removed by the workman whose special duty it is to attend to the filling of the pots, and the molten iron is caught in the vessels which are held under the spout. Two or three men usually pour into one mould at the same time, through different gateways or holes, by which means the streams of metal, having a shorter distance to run than if poured through one gate, have less risk of losing the proper degree of fluidity by cooling. It is a common practice in foundries to pour the metal in the afternoon. The smaller articles are taken from the flasks the same evening, and the larger ones on the following morning. After the sand is rubbed from them they are carried to an adjoining apartment, where any roughnesses are chipped away by the chisel, and they are otherwise suitably finished. Hollow articles are often cast in moulds composed of parts, some of which are of greensand and some of dry sand or loam. The casting of a hollow column is an example. The outer part of the mould is made in a flask of two parts with greensand, from a solid pattern of the column. A core somewhat longer than the mould, made of a mixture of sand and paste, baked dry, is then placed in the axis of the

hollow mould, its extremities resting upon the sand beyond. The thickness of the walls of the column will of course be in inverse proportion to the size of the core. Small columns may be cast lying horizontally, but larger ones

FIG. 12.—Mould for a Column.

should be cast vertically, and, if of much height, in sections. If cast lying down, they are liable to warp and to be of inferior strength in consequence of the opposite sides wanting uniformity of molecular structure and density. The casting of long, slender articles, such as ornamental railings, is simplified by a method patented by Mr. Jobson in England. He secures a finished brass or iron pattern to a plaster of Paris back or ramming block, upon which the mould is formed. When the model is removed the mould remains in the drag. A cope with a plane surface, or having a device corresponding to the other side of the pattern, and which has been formed from a reverse block, is then placed over the mould, and the necessary holes having been prepared, the metal is poured. Mr. James L. Jackson, of New York, has taken out a patent for making patterns entirely of plaster of Paris and other plastic materials, thereby greatly reducing their cost. They are swept with a templet which may be made to move in either straight or curved lines. The labor and time of making the large and accurate castings for the fronts of buildings are by this process very greatly reduced. A bed piece or rest, of plaster, is first swept with a templet, and after the surface of this is properly prepared, another layer of plaster mixture is spread on, and this swept with a templet of corresponding form but of larger size. In moulding, the pattern lies upon the rest when the first side is rammed in the drag. When the pattern is long it is sawed into transverse sections to facilitate the handling. These may be adjusted together and will serve the purpose of a whole piece. Greensand moulding is often practised with only part of a flask, the cope, the sand bed of the floor taking the place of the drag. A bed is carefully prepared and levelled, the pattern imbedded in its surface, and the sand well rammed about it. The pattern is then carefully cleaned and the surface of the bed levelled and dressed, leaving a certain portion of the pattern projecting above the surface. Parting sand is then sprinkled over both pattern and bed, and a cope is laid down and rammed, it being prop-

erly secured from rising by weights. The cope is then lifted off by a crane, and while suspended its surface is dressed and properly prepared. The pattern is lifted out, and the mould in the bed repaired and dressed, when the cope is replaced, the holes for pouring and for the escape of air and gases having been provided for. Being then securely weighted, to prevent rising from pressure of metal and gases, it is ready for the pouring of the metal. In fig. 3 a greensand floor mould is represented at *c*.—In the casting of metals, especially those having high melting points, there is always more or less production of gases, together with expansion of air; and if the operation were performed in a mould which was not porous, the bubbles would mar the surface of the casting as well as enter to a certain extent into its interior. It is therefore necessary that the mould should possess sufficient porosity to allow of the escape of aeriform matter. Moisture in a mould is only admissible in small castings which cool quickly. Used for large masses of molten iron, the amount of steam formed, together with the expanding gas, would not only endanger the mould, but also the workmen. Dry moulds made of loam are consequently used in heavy castings, partly for the above reasons, and partly because sand could not be properly manipulated or retained in place in large and massive castings. The casting of large cylinders, bed plates, and condensers for steamships is a very intricate process, requiring good engineering abilities, skill in draughting, and experience in the designer as well as in those who execute the work. The moulds are usually worked from drawings instead of being formed upon patterns. A single piece of machinery is often complex in form, and as the art of the moulder consists in forming a hollow cavity where the carpenter or cabinetmaker would make a solid body, it must be seen that he has a much more difficult task before him; for he has not only to form an inside structure similar to the future cast, but an outside one of a reverse form as well; and these two forms must be perfectly related to each other. He has also to provide channels and gateways for the pouring of the metal, and they must be so arranged as to secure its perfect flowing to every part, and as nearly as possible its simultaneous cooling. Allowance must also be made for shrinkage, and an almost infinite number of precautions, suited to particular exigencies as they arise, must be observed. The draughting requires great forethought and calculation, and the execution not only involves a perfect comprehension of the plan, but a constant vigilance in avoiding errors and causes of miscarriage. A description of the moulding and casting of a complex piece of machinery would require a very great detail of explanation and numerous illustrations, and then could not be comprehended except by repeated visits to the foundry. The moulding and casting of a simple cylinder will therefore be taken. A

loam mould, secured in a pit, and ready for casting, is represented in fig. 13. It is constructed in the following manner. An iron foundation plate is laid upon the floor of the

FIG. 13.—Loam Mould. *a*, Hollow mould, surrounding the core, and surrounded by the cope. *b*, Hollow inside of cope. *c, c*, Bolts holding cope together. *d*, Air tube for discharging air from core. *e, e*, Air tubes. *f, f*, Pouring holes.

foundry, and levelled. An iron ring, flat and of a breadth equal to the thickness of the walls of the core which is to be built upon it, and of a diameter equal to that of the inside of the future cylinder, is laid down, and the core is built upon it to the height desired. An apparatus for describing and sweeping the surface of the core is now erected, which is called a sweep, and consists of a spindle and templet, represented in fig. 14. An arm, *a*, supported by some portion of the building, holds the upper end of the spindle *b*, while the lower end

FIG. 14.—Sweeping the Core.

turns in a hole in the centre of the foundation plate. A collar, *e*, which may be adjusted at any required height, is provided with an arm, to which again the templet *d* is firmly held by means of a mortise, which slides over the arm, and may be set at any desired distance from the spindle. From the construction of the machine it will be perceived that it may be used to describe either the inner or outer surface of a cylinder; therefore it serves to give form both to the surface of the core and to the inner surface of the cope. After the sweep is placed in position the core is commenced by building up a cylinder of brickwork upon the circular plate, its dimensions being governed by the templet, which in sweeping about its axis should leave a small space between itself and the bricks to allow of finishing with loam. The bricks are laid up in loam, and the same

material is laid upon the surface until it has sufficient thickness to be scraped off by the templet, as shown in fig. 14. The top of the core may be swept and levelled by the arm, the templet being removed. If the cylinder is to be cast with a bottom, an iron plate is fitted to the upper end of the core, and a proper

FIG. 15.—Drying Ovens.

thickness of loam laid upon it. This may be built upon the core, or it may be done separately, and the parts put together after they are dried. When the core is finished it is lifted, by a crane by means of chains or rods attached to the circular plate upon which it rests, upon a car which passes on a track to one of the drying ovens represented in fig. 15. The templet is then placed at that distance from the spindle by which it will describe the inner cylindrical surface of the cope, which is built up with brickwork and loam in a similar man-

FIG. 16.—Sweeping the Cope.

ner with that used for the core, except that for convenience it is usually built in two sections (see fig. 16). Iron rods are laid in the brickwork, passing from top to bottom, and securely

fastened to the bottom plate. A cap is then made by fitting an iron plate to the top, adding brick and loam, and securing it by the rods which pass through the walls from the bottom plate. When finished, all these parts are washed with a mixture of charcoal or plumbago dust and water, the mixture being sometimes applied two or three times. A strong cross piece of iron is then fastened to the top of the cope, hoisted by means of a crane upon the carriage, and taken to the oven. After both core and cope have been thoroughly dried, they are lowered into a pit formed in the floor of the furnace. (See fig. 3, *h*.) Upon the bottom of this pit there is an iron foundation upon which the cope and the core both rest, and to which they are properly adjusted and secured. Care has been taken to provide the cope with the necessary holes for pouring and for the discharge of air. Sand is then thrown into the pit about the sides of the mould, and well tamped down to prevent any spreading during the casting. The relation of the parts is represented in fig. 13. A powerful expansive force is applied to the interior of the mould when the hot metal is poured in, and the greatest precautions must be taken to have all the iron fastenings as well as the sand tampings strong enough to withstand the pressure. Into the holes intended for the escape of air iron tubes are placed, of sufficient length to reach above a layer of loam which is now laid over the cope. Into the holes for pouring plugs are placed and the loam formed around them in cups, which are connected with channels through which the metal runs in pouring. In the figure a tube is seen leading a few inches downward from the lower part of the hollow of the core, then horizontally beyond the edge of the mould, and thence up to the surface of the foundry floor. This is for the purpose of carrying off gaseous products from the core. In casting a cylinder without a bottom, it will only be necessary to have a tube extend directly upward to the surface. It will be noticed that the holes for pouring are placed immediately over the hollow mould, and not, as in casting statuary, connected with channels in the cope entering at the bottom of the mould. The securing of the mould for the cylinder of a large steamer is a matter which requires the greatest vigilance. The pit into which it is lowered must be dry, and is generally built like a cistern and bricked and cemented on the sides and bottom; and care must be taken to keep the mould dry till the casting is done. The cope must be well bolted to the bars that come through the sides from the bottom. A rim of iron plating may be placed around the part that projects above the ground, reaching high enough above the top of the cope to hold a layer of sand. A heavy iron cross is then raised over the mould and fastened with bolts, by which and also by its weight it aids in sustaining the strain at the time of casting. This is called packing. Fig. 17 represents the packing of a mould for a large cylinder. To

furnish sufficient metal for the casting of a cylinder of 24 tons, two large cupola furnaces are required, capable of melting 10 or 12 tons of iron per hour. A reservoir which will con-

FIG. 17.—Packing the Mould of a Steam Cylinder.

tain 8 tons of the molten metal is erected at the side of the mould, at such an elevation that the metal will flow with a moderate current into the channels on the top; or two such reservoirs may be placed, one on either side, the rest of the metal being poured from kettles suspended by cranes. The reservoirs are tapped from a hole in the lower part, in the same manner as the cupola is tapped, but the kettles are turned by an apparatus of wheel work adjusted to the bail. Each kettle may contain from 4 to 6 tons of molten iron, and the apparatus for pouring them must be of the most substantial character; for if any part of it should break, severe accidents would be almost sure to follow. The melted metal in the reservoirs and kettles is kept covered with lumps of charcoal, which are raked off when the pouring is made. In the casting of cylinders, the shrinkage of the iron in cooling must always be particularly taken into consideration. This is quite uniform, and is one inch in 8 ft., or $\frac{1}{8}$ linear measure. The circumference of a cylinder, therefore, having a diameter of 8 ft., will shrink on cooling 3·14159 inches; and if it were cast over a perfectly incompressible core, it would necessarily be ruptured unless the core were removed before the shrinking began. Mr. Robert Cartwright has patented a process which has been used in casting the cylinders for the pneumatic piles for the great bridge over the Missouri river at Leavenworth, Kansas, with satisfactory results. It consists in making the core in sections and joining it together in such a way that it may be taken to pieces and removed immediately after the cast is made. It is designed especially for cylinders open at both ends, but may be varied so as to be used when they are cast with the bottom upward.—Brass and bronze founding is very similar in its details to that of iron.

The moulds for casting these alloys are made of the same material as for iron, although for the casting of fine articles of bronze a finer and more compact loam is used. The melting for large castings is usually done in a reverberatory furnace, charcoal being the best fuel. Cupolas are sometimes used, but at a great waste of the more oxidizable alloy. When the quantity is not large, black-lead crucibles are used, which are heated in a furnace placed beneath a platform raised one or two feet above the floor, for convenience of handling. The construction of a furnace for melting brass and bronze is shown in fig. 18, the first flue being represented in section. The melting point of brass containing 33 per cent. of zinc is between 1,800° and 1,900° F. That which contains more zinc melts at a lower, and that which contains less at a higher temperature. The copper is usually melted first and the zinc added. Bronze containing about 10 per cent. of tin requires heating some 200° higher; but bell metal, containing 22 per cent. of tin, melts at about the same temperature as ordinary brass. Anthracite coal is used for heating the crucibles, and

FIG. 18.—Furnace for Melting Brass.

the surface of the alloy is covered with charcoal, which of course is consumed and adds to the heat, at the same time that it prevents oxidation. The pouring is performed in the same manner as for iron. The screw propellers for first-class steamships are made of bronze to enable them to resist the action of salt water. The moulds are of loam, and for small wheels are made upon patterns, but for large ones are swept and modelled with tools. Sometimes the hub of the wheel is swept with a templet, while the wings are separately moulded on a pattern. This is the most convenient, and perhaps the most perfect method, as the precise curve can more readily be given to the surface of the wings. The alloy for propeller wheels contains 10 per cent. of tin. The casting of bells is usually performed in the following manner: The mould of a small bell is made with a pattern, the process being very simple

when compared to that required for pieces of machinery. It may be made of moulding sand or of loam. If of the former, the pattern, which is of the exact size and form of the future bell, is laid, mouth downward, upon a turn-over board, and dusted with coke dust or charcoal. A drag of sufficient depth is then placed upon the board and rammed full of sand. The bottom board is then clamped on, and the flask is turned over and a cope adjusted and rammed full of sand, the necessary holes being provided for. The cope is then taken off, the pattern removed, the mould properly dusted with parting sand, and the parts replaced and clamped together, when the piece is ready for casting. For large bells the method pursued is similar to that for large cast-iron cylinders. A sweep is constructed having a templet which may be used to sweep the interior of the cope or the surface of the core. The core is built of brick and loam upon an iron plate, and swept in the same manner as the core of a cylinder, and the cope, made of brick and loam also, and bolted, which is to form the exterior of the bell, is swept like the cope of a cylinder. The surfaces are then washed with charcoal or plumbago mixture, and dried in the oven in the usual way. The parts are then sunk in a pit upon a bed plate, secured, and the pit well rammed with sand, pouring and vent holes having been provided. The top of the cope is covered with loam through which holes are made connecting with those in the cope, and channels are formed in it to receive the metal. The core must be so constructed that it will yield when the metal shrinks on cooling, which is the case with bronze as with cast iron. If rupture is not produced by rigidity of the core, the metal will have a strain of tension which will be likely to cause fracture when the bell is struck. It may be constructed with bands of straw wound around it, over which loam is spread before finishing with the templet. The Messrs. Meneely of West Troy, N. Y., use perforated cases (fig. 19), upon which the core as well as the cope is formed. The cone upon which the core is made before being spread with loam is wound with ropes of straw, which yield sufficiently for the contraction of the bell. The outer case is spread with loam on the interior, the holes with which it is pierced allowing of the expulsion of expanding air and gases. For casting of heavy guns, see *CANNON*.—*CASTING in the Fine Arts*. Before treating of the casting of statuary and other

FIG. 19.—Meneely's Cases.

articles of sculpture in metals, it will be proper to describe the more simple methods of casting them in plaster of Paris. This substance possesses peculiar properties which give it a wide application in nearly all the arts. Gypsum, from which plaster of Paris is made by calcination, is a hydrated sulphate of lime containing about 20 per cent. of water by weight. Where a large, but not necessarily definite quantity of this water is driven off by a gentle heat, the gypsum, after being ground and sifted, becomes the beautiful white article known as plaster of Paris. This substance possesses the property of recombining with the same amount of water which the heat had driven off. When mixing it for use, however, a much larger quantity of water is used, sometimes twice or three times as much; but for making strong moulds, as little is used as will answer to render the mixture fluid. A definite quantity of water enters into chemical combination, and the rest is held in the pores of the plaster when it sets, most of it afterward passing away by evaporation. A proper mixture of plaster and water possesses the property of running into the minutest parts of a mould, so that the finest lines may be copied with considerable approach to perfection. For this reason it is often used in electrotyping, for taking casts, upon which the metal is subsequently deposited by galvanic action; and also for taking casts of leaves of plants, and other articles of a similar character. The mixture sets in 20 or 30 minutes after being stirred, depending upon the quality and quantity of the plaster used, and upon the presence of other substances, such as lime, alum, or cream of tartar, which may have been added to it. The casting of models in bass relief is quite a simple process, and is performed in the following manner. The mould is made by simply laying the model, which is usually made upon a plate of glass or a slate, upon a table and pouring over it the mixture of plaster and water. If the model is in clay, it should be wet with water, and the slate slightly greased with lard oil. It is not necessary to build a barrier about the edge of the slate, for the mixture poured on with a cup or a large spoon, first over the object, soon becomes thick enough to allow of its being spread over the slate without running off. The mould may be made from one half to one and a half inch in thickness. In from 50 to 70 minutes it will set firmly enough for removal, which may be done by carefully introducing the blade of a stout knife under its edge, and gently raising it with the assistance of the hand. If the model is not undercut, the mould may be used in one piece for casting several copies. If, however, projections are left, the mould must be broken away from the cast, or else it must be composed of more than one piece so that it may be drawn. When a mould is broken off it is called a waste mould, and when in parts it is called a piece mould. When a model is undercut it may be made flush by

adding clay. A whole mould may then be taken, and such portions as were added may be removed from the cast by appropriate tools, thus avoiding the use of a piece mould. When the mould is made in parts, it may be done by pouring the plaster over a portion, letting it set, removing it and paring the edge, which is slightly oiled or washed with a mixture of clay and water, replacing it, and adding one or more sections afterward. Another plan, which may be practised with great facility, is to make the mould in one piece and afterward saw it into sections with a very thin, fine saw. If a very fine impression is desired, the mould should be saturated with water, laid upon its back, and, if composed of more than one piece, held in place by supports. A mixture of plaster and water, carefully stirred together, is then turned into the mould and over the plane surface, to an extent sufficient to form a base to the cast, of any desired dimensions. If several copies are wanted, and there are no very fine lines to be preserved, the mould may be varnished with shellac and alcohol. Previous to applying the varnish it may be painted with linseed oil, in which case it should first be dried; but if oil is not used, the varnish may be applied to the green mould with more advantage than to allow it to dry. In removing the mould from the cast a good deal of care is required, and successful manipulation is not attained without considerable experience. In making a cast of a clay model of a bust, two methods may be pursued. The entire model may be covered over with the plaster mixture, by throwing it on in a creamy state with a cup or spoon, and lastly by spreading it on with the hands, until the proper thickness is attained to give sufficient strength; and

FIG. 20.—Bust covered with Plaster Mould.

then, after setting, the mould may be cut into sections with a very thin saw and carefully removed. (See fig. 20.) The process more usually preferred is to apply the plaster

in sections by the method of parting. A common way is to make only two sections, the smaller one embracing merely the crown of the head. This plan requires that the frame on which the bust was modelled shall be so constructed that it may be taken apart and removed by the hand, after the plaster is well set. After the mould has been carefully cleaned with water and a soft brush, the parts are put together and bound by a strong cord or rope, and the seams stopped on the external surface with cream of plaster. After this is set the mould is saturated with water. The bust is then cast by turning into the cavity successive batches of cream of plaster, at the same time turning the mould about in such a manner as to cause the plaster to run into all the lines and furrows, and to be deposited in sufficient thickness all over the interior surface. In this way a hollow cast is made without the use of a core. After the plaster is well set, the bust may be placed upon a table and the mould

FIG. 21.—Machine for Casting a Bust.

chipped off with a chisel and mallet. This is an operation which requires great care, and can only be done by an experienced hand, and by none so well as by the artist himself. The casting of a bust is rendered much easier by swinging the mould in a pair of strong, concentric iron rings. (See fig. 21.) This device allows it to be turned with ease in any position, greatly facilitates the operation, and diminishes the chances of making a defective cast. The plaster bust is used as a model by the marble cutter in reproducing the work of the artist. When several copies in plaster are desired, it is used as a model on which to form a piece mould, which may serve in producing an indefinite number of copies. A statue in plaster may be cast in a variety of ways, depending upon the purpose for which it is intended; whether to be preserved as a plaster statue, or copied in marble, or to be used as a model from which to make a bronze cast. If it is to be preserved as a statue, it will be cast as nearly as may be in one piece; but if to be used as a model or pattern by the bronze founder, it

may either be taken in as many pieces as it is designed to make the bronze casting, or it may be cast in one piece, or in as few as possible and then joined together, leaving the bronze founder to make his selection of sections in which to take his loam mould. The method of proceeding to make a mould for a plaster statue from a clay model is as follows: The model is made pretty wet, so that the moisture from the plaster will not be too much absorbed before it sets. Then a mixture of plaster and water is spread over a certain selected portion of the statue, say the front half of the head and chest, a barrier of clay having been previously erected along the boundary line. After the plaster has set the clay barrier is removed, any injuries that may have happened to the back part of the head and chest are repaired, and the edges of the plaster soaped or washed with a mixture of clay and water. A plaster mixture is then spread over the back of the head and chest, the two applications encasing the whole body above the waist. The remainder of the body may be taken in two or four pieces. If one limb is partially raised or much separated from the other, it may taken in two halves by itself; but if not, the lower part of the body and both limbs may be moulded in two pieces, one before and one behind. Very often one arm will be taken with the chest, while the other one will be taken separately. After setting, all the pieces may be removed, and of course some of the clay will be brought away with them; but that is of no consequence if the plaster mould is a good one, because, with care, a copy is now secured. After removal, the separate pieces are cleaned with water and the careful use of a brush. The pieces may then be put together and the different parts of the statue cast in the same manner as a bust is cast. Measurements have been taken from certain points on the clay model to the dividing lines, and recorded. These points and lines are reproduced on the plaster casts, so that their edges may be cut to precisely fit each other and preserve the symmetry of the original model. The statue is then completed by putting all the parts together and cementing them with plaster mixture, which is spread on over the seams on the inside by the hand, introduced through an opening made for that purpose, which is afterward repaired in the same way. If a bronze copy is to be taken and the bronze founder prefers to have the pieces separate, of course the joining will not be done. In cases where the statue is clad to the throat, there will be one additional piece of work to be performed to prepare it for the bronze founder, which is to detach the head, and add plaster in a conical form to the neck, which is to be fitted into a collar; for the head should be cast separately in bronze, and the artist should separate it and fit it in its joint himself, so that the proper pose shall be preserved.—A statue in bronze is cast in two or more pieces, generally in from four to six, the number of pieces usually be-

ing in inverse proportion to the mechanical and technical skill of the founder. The principal difficulty in casting a statue whole is the cracking and straining of parts on cooling and contraction of the metal. If, however, this can be cast very thin, and uniformly so in every part, avoiding masses where there are folds of dress or any irregular surfaces, no cracking may occur. It is not always, however, desirable to avoid division, because the parts may be skilfully joined and much tedious labor saved. In the case of such a work as the statue of Pallas, shown in fig. 23, the whole figure, with the exception of the right arm and upper part of the spear, which are to be removed, may be cast in one piece. If of plaster, we will suppose the model to have been varnished with a solution of shellac in alcohol, previous to which it may have been painted with linseed oil and dried, to harden the surface; but this may have been omitted. The statue is laid upon some very fine loam in the iron flask in which it is to be cast, and well adjusted in a bed prepared for it, which fits its surface perfectly, giving a firm support. A quantity of fine loam, which is only to be obtained in a few localities, possessing peculiar physical properties, adhesive and yet porous, after having been ground several times in a mill resembling a sugar mill, is taken in small quantities at a time and pressed and hammered into compact sections upon the surface

FIG. 22.—Piece Mould for a Statue.

of the model. Each section must embrace such parts as will allow of its being drawn. The process is similar to that of making a piece mould with plaster of Paris, except that the material in the latter case is spread on in a plastic condition, while the former is rammed and hammered on. The process is a very difficult and tedious one, requiring several weeks and sometimes months to make a mould for a life-size statue. In Germany a composition is used which is spread on like plaster and allowed to harden. Whatever material is employed, the problem is to fit together firm but

porous sections over the whole surface, of such forms and dimensions as will be most convenient for drawing from the model, and also for supporting each other after the model is removed. (See fig. 22.) Iron rods and stays are placed in the section while they are being hammered together, and channels leading from the top to the bottom must be formed in them through which to pour the metal. They are represented in the sectional cut, fig. 24. After this loam piece mould is completed, a number of the sections are laid in a bed of loam in a flask, and the forming of the core is commenced within the cavity. It is made of the same material, a very fine loam, which was used for the outer mould, except that sometimes it has mixed with it a small portion of molasses or paste. It is hammered together in the same way, and when completed is a facsimile of the original model. It must contain an iron frame, or a number of iron rods, to strengthen it, and also some pierced tubing for carrying off the expanded gases which are generated in pouring. Iron rods must also be passed in two or more places through it, their ends entering and resting in the outer mould. When the latter has been carried up piece by piece and the hollow completely filled with the hammered loam, it is to be removed and the loam statue placed in the proper position, and its surface carefully pared down to a uniform depth. This forms the core, which is represented in fig. 23 by the

FIG. 23.—Statue and Core of Mould.

smaller statue. When placed within the outer mould and properly adjusted, there will be a space, equal in depth to the thickness of the paring, between every part of the surface

of the core and the inner surface of the outer mould. It will be observed that in this case the holes for pouring and for the escape of air are made at the base of the statue, which for

FIG. 24.—Perpendicular Section of Mould. *a, a, a*. Hollow mould. *b, b*. Channel in the cope for pouring the metal. *c, c*. Channel for discharging gases. *d, d, d, d*. Iron supports for holding core in place. *e, e*. Air tube in core.

casting is to be turned upside down. In casting statues in one piece, they are usually placed in this position. A perpendicular section through both outer and inner parts of the mould and the containing flask has the appearance represented in fig. 24, with the exception that the iron framework for strengthening the parts has been omitted. Both core and outer piece mould are now placed in the oven and baked, having previously been carefully dressed and cleaned, and then washed with a mixture of water and plumbago or charcoal, or both combined. After the proper amount of baking, which should leave them dry and porous, the parts are taken and placed together in a flask, each part of which contains a bed perfectly adjusted to the surface of the mould. The flask is then carefully secured with bolts to prevent any expansion or opening of the mould during the casting. Bronze containing 10 per cent. of tin requires a heat of about 2,000° F. to

bring it to the proper degree of fluidity. It is considered rather a refractory metal, liable to fly, and requires skill and experience for its mastery. The pouring is done in the same manner as for bell casting, and the same crucibles and furnaces are used. After the metal has cooled the flask is removed, the loam knocked off, and the branches of metal which fill the spaces of the air holes as well as those for pouring are cut off. When the statue is cast in sections the edges are made somewhat thicker than the other parts, and lips are also provided, to meet in the interior so that they may be bolted together. The thickness of the edges is for supplying material for hammering them together till the seams are obliterated. The parts are usually immersed for a few hours in a weak pickle of acidulated water, for the purpose of loosening and aiding in the removal of silicious matter which has become incorporated with the surface of the bronze. All the sections are then bolted together, the edges smoothly hammered till the joints are perfect, all roughnesses filed away, and the whole surface chased with appropriate tools. An old method, which is still employed in Italy, is to make a core composed of potter's clay, brick dust, cow's hair, or some other composition, and over this model the figure in wax. Then the outer mould is formed upon this, of some composition, of which loam forms the principal part. Iron rods for supports and tubes are provided and adjusted in the same way as in piece moulding. The whole is then dried and baked in an oven until the wax is melted and cleaned, and the mould rendered sufficiently porous.

CASTLEBAR, a town of Ireland, capital of county Mayo, at the N. end of a lake of the same name, 41 m. N. N. W. of Galway; pop. about 3,000. The principal street is a mile long, and it contains a square with handsome houses. It has a fine parish church, a Catholic chapel, a Wesleyan meeting house, several schools and hospitals, barracks for artillery and infantry, a court house, and a county jail. The principal trade is in agricultural products. Linen, linen yarn, and other articles are manufactured. The town was captured in 1798 by a French force under Gen. Humbert, who had landed at Killala bay; but they evacuated it shortly afterward, on the approach of the British under Lord Cornwallis.

CASTLE CAREY, a market town and parish of Somersetshire, England, on the Great Western railway, 22 m. S. S. W. of Bath; pop. in 1871, 5,518. It contains a manor house in which Charles II. took refuge after the battle of Worcester.

CASTLEMAIN, a town of Australia, in the colony of Victoria, situated at the junction of Barker's and Forest creeks, 65 m. N. W. of Melbourne; pop. in 1871, 7,308. In the early days of gold mining it was a place of great importance, the diggings in the neighborhood being among the first discovered in Australia. It is a principal station on the Victoria railway.

CASTLEREAGH, Robert Stewart, viscount and marquis of Londonderry, a British statesman, born at the family seat of Mount Stewart, county Down, Ireland, June 18, 1769, died by his own hand at his seat of North Cray place, Kent, England, Aug. 12, 1822. He attended the grammar school at Armagh, and completed his education at Cambridge. In 1789 he was elected to the Irish parliament for the county Down, after a sharp contest, which is said to have cost his family over £25,000. In 1794 he was returned to the British house of commons, as a member for the borough of Tregony. In May, 1796, he was again returned to the British parliament for Orford; but relinquishing his seat in July, 1797, he was re-elected to the Irish parliament, as representative of the county Down, and appointed keeper of the privy seal of Ireland. In 1796 he became Viscount Castlereagh, on the elevation of his father to the marquise of Londonderry. In the beginning of 1798 he became chief secretary to the lord lieutenant, and an Irish privy councillor. The rebellion which invited and accompanied the landing of Gen. Humbert in 1798 was crushed by Castlereagh. It was mainly through his instrumentality that the act of union was passed. When this measure was consummated, he quitted the Irish government, execrated by the majority of his countrymen. He represented his native county in the first imperial parliament, which assembled in February, 1801, and also in the second, which convened in September of the ensuing year. In the beginning of 1802 he was appointed a privy councillor of Great Britain, and president of the board of control. He retained that office after the retirement of Mr. Pitt, and throughout the Addington administration. In July, 1805, after Mr. Pitt's return to power, Castlereagh joined his cabinet as secretary at war and for the colonies. Having lost his seat for Down, he was returned in 1806 for Boroughbridge; and relinquishing his office after Mr. Pitt's death, he was returned for the following parliament, in the same year, for the borough of Plympton Earle. He now went into opposition against Fox and Grenville, and attacked their peace policy. In 1807, upon the formation of the Portland cabinet, he again became secretary at war, and was re-elected by his last constituency for the parliament which met in May of that year. While a member of this administration, he incurred in 1809 the responsibility of the ill-advised Walcheren expedition, in reference to which Mr. Canning, his colleague and secretary for foreign affairs, assailed him with such warmth of personality, that a duel ensued between them, and both retired from office. Castlereagh soon returned to the ministry, and assumed Canning's post, in which he gained a position so commanding, that on Mr. Perceval's death, in 1812, he was regarded as the ministerial leader in the house of commons. In November, 1812, he was once more returned for the

county Down, retaining that seat in the next two parliaments, which met in August, 1818, and in April, 1820. In 1814, as British plenipotentiary, he took part in the conferences of Châtillon, and was influential in persuading the allies not to lay down their arms unless Napoleon agreed to limit France to the boundary of 1792. This Napoleon refused to do; and that great campaign was begun which ended in the capitulation of Paris and the abdication of Napoleon. At first Castlereagh would not concur, in behalf of England, in the measure by which Napoleon was permitted to retain the title of emperor and retire to Elba. After the treaty was signed, however, he reluctantly acceded to it. He took part in the congress of Vienna, both before and during the hundred days. Subsequently he supported George IV. in his schemes for getting rid of Queen Caroline, and was the author of the harsh measures for the repression of discontent caused by general distress and dearness of provisions. The struggles of the constitutionalists in Spain and Portugal called for active interference on the part of the holy alliance, and Castlereagh was on the point of joining the congress of Verona when he fell into a state of melancholy, in which he committed suicide by opening the carotid artery with a penknife. The coroner's jury declared the act to have been committed in a state of lunacy. He had become second marquis of Londonderry, April 8, 1821. His correspondence was edited by his brother, the third marquis, in 1850.

CASTLETON, a post village and township of Rutland co., Vt., on Castleton river, at the intersection of the Rutland and Washington, and the Rensselaer and Saratoga railroads, 12 m. W. of Rutland; pop. in 1870, 3,243. It is noted for its slate quarries, and is the seat of a seminary and a state normal school.

CASTLETOWN, the capital of the Isle of Man, England, on a bay of the same name, near the S. extremity of the island; pop. in 1871, 2,373. It contains King William's college, founded in 1830, and Castle Rushen, said to have been built by a Danish prince in 960. It is the seat of the governor and the courts of law.

CASTOR, a substance somewhat resembling musk, secreted by the beaver. It is of the consistency of honey, and has a strong, penetrating, fetid, and volatile odor, which is lost when the substance is dried and hardened. It is used to some extent in medicine as an antispasmodic and stimulant, and is thought to act especially upon the nervous system. It was known and recommended by Pliny and Dioscorides, but it has not a high reputation among modern practitioners; and as it is often largely adulterated, there will be little cause for regret should its use be discontinued. The article considered the best is obtained from Russia. The American beaver produces an inferior quality. Benzoic acid is recognized among the numerous organic compounds of which this substance consists.

CASTOR OIL, a mild purgative obtained from the nuts of the castor oil plant, the *ricinus communis* or *palma Christi*. *Ricinus* is an apetalous genus of plants belonging to the natural order *euphorbiaceæ*. It was originally a native of Asia, and was used by the nations of antiquity, but is now naturalized in Africa, America, and the south of Europe. The characters of this genus are: Leaves alternate, stipulate, palmate, glands at apex of petiole. Flowers in terminal panicles; monœcious, no petals; calyx 3-5 parted, valvate; filaments numerous, polyadelphous; style short, stigmas 3, bipartite, feathery; ovary globose, 3-celled, with an ovule in each cell; fruit capsular, triccocous. The *R. communis* or *palma Christi* has petate palmate leaves, with lanceolate serrated lobes; an herbaceous glaucous stem, of a purplish red color upward; and flowers in long green and glaucous spikes, springing from the divisions of the branches, the males from the lower part

Castor Oil Plant.

of the spike, the females from the upper. The capsules are prickly. It varies in size in different countries. In some parts of Europe it is not more than three or four feet high, but in India it is a tree, and in Spain it attains fair dimensions. The native country of *R. communis* is unknown; it is conjectured to be Barbary. The castor oil plant was known in very ancient times, both to the Egyptians and the Greeks. The latter called it *croton*, a name bestowed by modern botanists on another genus of euphorbiaceous plants, one species of which yields the strongly purgative oil called *oleum tiglii* or croton oil. Numerous varieties of *R. communis* exist in various localities, differing not only in color and the peculiar condition of the stem, but in stature and duration. In warm countries it is ligneous and perennial; in cold regions, annual and herbaceous. The entire plant possesses active properties, but the oil extracted from the seeds is alone employed in

Europe. The ancients administered the seeds entire, but their variable action, producing sometimes even fatal effects, led to their disuse. The oil is of comparatively recent introduction. The seeds were formerly known in the shops as *semina ricini* or *semina cataputiae majoris*. They are about the size of a small bean, obtuse at both ends, the surface being smooth, shining, and beautifully marbled. The skin consists of three tunics; the nucleus or kernel consists of an oily albumen and an embryo, the cotyledons of which are membranous or foliaceous. The outer shell is devoid of taste. According to Dr. Dierbach, the active principle resides in the inner coat; others assert that the purgative principle resides in the embryo. Mérat and De Lens have shown in the *Dictionnaire des sciences médicales*, t. xlix., that the active principle is diffused through the entire substance of the kernel, though possibly with more intensity in the embryo.—The quality of castor oil depends on the greater or less maturity of the seeds, the peculiar variety of the plant from which they have been obtained, and the accidental or intentional admixture of other seeds before the process of extraction. Both in India and America much heat was formerly employed in the process, and this was injurious to the quality of the oil. During the application of heat a volatile principle escaped, which was so irritating that the workmen had to protect their faces by masks. The French method is the best. The fresh seeds are bruised, and then put into a cold press. The oil is expressed and allowed to stand some time, to permit the albumen, mucilage, and other matters to subside; or it is filtered, to separate them more rapidly. The produce is equal to about one third of the seeds employed, and the oil possesses all its natural qualities. Both the French and Italian oils are much milder than oil procured from tropical countries. Oil of good quality is a thickish fluid of a very pale yellow color, the best being almost limpid, with a slightly nauseous odor and an oily taste, mild at first, but causing a feeling at the back of the throat, more or less intense, according to the freshness of the specimen. Bad oil is rancid and disagreeable. Castor oil is much used in the East, France, Italy, and other countries, for burning, as well as for medicinal purposes.—The cathartic action of castor oil seems to depend upon the development of an acrid principle, identical with or analogous to that of croton, modified by the much larger amount of bland oil with which it is associated. When pure, it is a mild and certain aperient or laxative, commonly operating without griping or other inconvenience, very soon after it is taken. It is deemed the most proper laxative in many inflammatory states of the abdomen, the kidneys, and the bladder. It is also deemed a most eligible medicine in piles and other affections of the rectum. Its use is liable to be followed by more or less constipation. The chief objection to its use is its repulsive taste.

From 15 to 20 drops of pure liquor potassæ will usually saponify half an ounce of castor oil, to which one ounce of distilled water and a drachm of spirits of pimento or of nutmeg may be added. This makes an emulsion which is effective and not unpleasant to the taste. The manufacture of castor oil is actively carried on in the United States, especially at St. Louis, the beans being produced in southern Illinois.

CASTOR AND POLLUX, called also the DioscURI, or sons of Zeus, famous heroes in Greek mythology. According to Homer, they were sons of Tyndareus and Leda, and brothers of Helen and Clytemnestra, and hence are often called the Tyndaridæ. Castor excelled in taming horses, and Pollux in the game of boxing. Though buried, they were taken from the earth before the siege of Troy, became immortal and honored as gods, and sometimes appeared among men. The legend was compli-

Castor and Pollux.

cated by subsequent poets. According to some, the DioscURI were sons of Leda and of Jupiter disguised as a swan or a star; according to others, Pollux only had this divine origin and the privilege of immortality. The place of their birth was variously said to be Amyclæ, Mount Taygetus, and the island of Pephnos. They are fabled to have attacked and ravaged Attica, and to have brought back their sister Helen, who had been stolen away by Theseus. They took part in the Calydonian boar hunt, and accompanied the expedition of the Argonauts, during which Pollux vanquished with the cæstus the giant Amycus, king of the Bebryces, and founded the city of Dioscurias in Colchis. Associated with Idas and Lynceus, sons of Aphareus, they plundered Arcadia; but in a quarrel which arose concerning the division of the spoil, Castor, the mortal, perished by the hands of Lynceus, who in his turn fell under

the blows of Pollux, while Idas was struck with a thunderbolt by Jupiter. According to another tradition, Castor was slain in a war between Athens and Lacedæmon. Jupiter permitted Pollux to pass alternately one day with his brother on Olympus and another on the earth. The worship of these brothers was established by the Achæans, adopted by the Dorians, and spread throughout Greece, Italy, and Sicily. They were the tutelary gods of hospitality, presided over gymnastic exercises, and were eminently the mighty helpers of man. They calmed tempests, appearing as light flames on the tips of the masts. They sometimes appeared in battle, riding on magnificent white steeds at the head of the army. By their assistance the Romans believed themselves to have gained the battle of Lake Regillus. Placed among the stars, they became the constellation Gemini. In works of art they are usually represented as young horsemen in white attire, with a purple robe, armed with the lance, and wearing a helmet crowned with stars. At Rome the men swore by the temple of Pollux, *Ædopol*, and the women by that of Castor, *Æcastor*. Around the ancient temple consecrated to them in the forum the equites marched in magnificent procession every year on July 15.

CASTOR RIVER, a stream of S. E. Missouri, which rises in St. François co., flows S., communicates by several arms with a group of small lakes in Stoddard co., and afterward unites with the Whitewater river. The stream thus formed, which is sometimes called the Castor, but more frequently the Whitewater, flows through a low swampy region, in which most of the streams spread themselves over a large surface and form extensive marshes or lakes. It receives the outlet of Lake Pemisco, and finally discharges itself into Big lake.

CASTRATION, a surgical operation practised upon some of the domestic animals, which consists in taking away the necessary and essential organs of reproduction, namely, the testicles in the male or the ovaries in the female. When performed upon the female, the operation is more commonly known as spaying. The object to be accomplished in either case is to moderate the impetuosity of the animals, to render them more docile and submissive, or more adapted to the kind of labor required of them, to increase their size, or to dispose the system to the accumulation of fat. The advantages which it sometimes confers in these respects are, however, often more than counterbalanced by other effects. Thus it undoubtedly diminishes the activity, the courage, the endurance, and even the intelligence, or at least the quickness of its manifestation. It is not therefore an operation to be performed on all animals, even of the male sex, indiscriminately, but should be applied with judgment only to those cases in which it is required by the special conditions, the particular employment, or the peculiar natural disposition of the animal. Castration may be performed at all ages; but its effects are

more decided if performed before than after the age of puberty. In the first case, the animal never arrives at the usual fully developed adult condition, and, if of the male sex, does not acquire the external marks which distinguish him from the female, nor the general masculine bodily contour. On the other hand, if these sexual characters have already been developed, they do not disappear on castration, and the animal simply loses the power of reproducing his species. (See *EVNUCH*.)

CASTRÉN, Matthias Alexander, a Finnish philologist, born at Tervola, Dec. 2, 1813, died in Helsingfors, May 7, 1852. He devoted himself to collecting the monuments of the genius of Finland scattered through the various tribes, and as a preparation he undertook in 1838 to travel on foot through Finnish Lapland. He then visited Karelia, to make himself more familiar with the language, with a view to the translation into Swedish of the celebrated popular poem, the "Kalevala." Aided by government, he pursued his investigations through Norwegian and Russian Lapland, and even through the land of the Samoyeds of Europe and Siberia. He was appointed linguist and ethnographer to the academy of St. Petersburg, and with the aid of the university of Helsingfors he extended his researches throughout Siberia, from the frontiers of China to the shores of the Arctic ocean. With feeble constitution and delicate health, he accomplished extraordinary labors, and sent home, in addition to the documents connected with his own studies, reports and letters of great value. Many of these were published in the Russian and Swedish periodicals of the day. Castrén was honored on his return to his country, in 1851, a year before his death, with the office of first professor of the Finnish language and literature at the university of Helsingfors. The literary society of Finland and the academy of St. Petersburg caused his writings to be published after his death, the latter body appointing Schiefner as editor of the works, published in St. Petersburg in German in 1853 and 1856, while Finnish editions were brought out at Helsingfors in 1852, 1853, and 1855, and a German edition of part of them appeared also in Leipsic. Among his works are *Elementa Grammatices Tschermisæ*, *Elementa Grammatices Syrjanæ*, *De Affixis Personalibus Linguarum Altaicarum*, and an Ostiak grammar in German. His Samoyed grammar and dictionary were published in St. Petersburg in 1854 and 1855, and his Tungusian dictionary in 1857. Borg published in 1853 a biographical sketch of Castrén, and a monument has been dedicated to his memory at Helsingfors.

CASTRES, a town of Languedoc, France, department of Tarn, 20 m. S. E. of Albi; pop. in 1866, 21,357. It lies in a fertile valley on both sides of the river Agout, which is here crossed by two stone bridges. It is the seat of a Protestant consistory, having been one of the first towns to embrace the doctrines of Calvin. It

is noted for its fine wool-dyed cloths, and has manufactures of silk, woollen, and cotton goods, linen, paper, soap, &c. Castres was a flourishing place in the 12th century. It suffered much in the religious wars of the 16th century, and its fortifications were destroyed by Louis XIII. in 1629. It was long the residence of Henry IV. during his religious wars.

CASTRI. See DELPHI.

CASTRIOT, George. See SCANDERBEG.

CASTRO, Henry, a Texan pioneer, of Portuguese descent, born in France in 1786, died in Monterey, Mexico, in 1861. He was an officer of the Paris national guard in 1814, and after the overthrow of Napoleon came to the United States, where he was naturalized, and appointed in 1827 Neapolitan consul at Providence, R. I. In 1838 he went to Paris as a partner in the banking house of Laffitte, and in 1842 he became consul general in that city of the republic of Texas. Having received a grant of land on the banks of the Medina river, he began in 1840 to send out emigrants to Galveston; and though the first attempt was unfortunate, he succeeded in 1844 in establishing a settlement on the site of the present town of Castroville; and in the next two years he founded Quihi and Vandenberg. The number of his emigrant vessels amounted in 1846 to 26, which brought over 485 families and 457 single persons, chiefly Alsations. In 1847 he founded Dhanis. All his settlements subsequently constituted Medina county, with Castroville as the capital.

CASTRO, Ines de, wife of the crown prince Dom Pedro of Portugal, assassinated in 1355. She was a daughter of Dom Pedro Fernandez de Castro, a descendant of the royal house of Castile, and a maid of honor to Constantia, first wife of Pedro. After Constantia's death in 1344, Pedro, fascinated by the extraordinary beauty of Ines, contracted a secret marriage with her, which, when a few years afterward it was disclosed to his father Alfonso IV., met a violent opposition from the king. The apprehension that the children of Ines might interfere with the claims to the throne of Pedro's children by his first wife, also preyed upon the mind of Alfonso. Her death was therefore resolved upon by the king, who caused her to be assassinated while Pedro was on a hunting excursion. When Pedro came home and found the bleeding corpse of his wife, his mother and the archbishop of Braga succeeded with the greatest difficulty in restraining him from taking vengeance upon the king. After the king's death in 1357 his wrath broke out with increased fury. One of the assassins succeeded in escaping to Aragon. The other two, who had sought protection at the court of Pedro the Cruel in Castile, were surrendered to the king of Portugal, who, after subjecting them to torture, had their hearts torn out, their bodies burnt, and their ashes scattered to the winds. He convened a council at Castanheda, when, in the presence of the nobility and the court, he produced the

papal documents and the evidence of the archbishop of Guarda, the attending priest, in order to establish by irrefragable proof the legitimacy of his marriage with Ines. The remains of Ines were then exhumed, her corpse was put upon the throne, clothed with the insignia of royalty, and the dignitaries of the kingdom approached to kiss the hem of the royal garment. Ines was afterward buried with great pomp at Alcobaca, the king, the bishops, the lords and officers of Portugal following the funeral procession on foot, a distance of 60 miles. A superb monument was dedicated to her at Alcobaca. Gomes in Portugal, Count Soden in Germany, and Feith in Holland have founded tragedies upon the incidents of Ines de Castro's life; but the most remarkable tribute paid to her memory is that of Camoens in the "Lusiad."

CASTRO, João de, a Portuguese naval hero and explorer, born in Lisbon in February, 1500, died in Goa, June 6, 1548. He belonged to an ancient family, and early became proficient in mathematics, having as teacher Pedro Nunez, and as fellow student the infante Dom Luis. He accompanied the latter in the expedition to Tunis in 1533, after having been previously knighted by the governor of Tangier; a similar honor was offered to him at Tunis by Charles V., but declined. In 1538 he was made commander of a small religious order, and soon afterward went with his uncle to Goa, where he served against the Moors. In 1540 he explored the Red sea under Estevão da Gama; in 1543 he was placed in command of a naval expedition for the extirpation of piracy; and in 1545 he was appointed councillor of the crown and governor of Goa. In 1546 he gained a celebrated victory over the Moors at Diu, and was celebrated by Camoens as *Castro forte* (the powerful Castro). The king of Portugal, though never partial to him, appointed him viceroy of India, Oct. 13, 1547. He died soon afterward in the arms of St. Francis Xavier, and a statue was erected in his honor at Goa. His remains were removed in 1576 to Portugal, and deposited with great pomp in the convent of Bemfica. His MS. log book (*Roteiro*) of his hydrographical investigations in the Red sea, preserved in the British museum, was first published in Paris in 1833, and possesses great scientific merit. He left also MS. narratives of his voyage from Lisbon to Goa, and from Goa to Diu. His biography was published in Lisbon in 1651, by Jacintho Freyre de Andrada.

CASTRO DEL RIO, a town of Spain, on the Guadajoz, in the province and 16 m. S. E. of Cordova; pop. about 9,000. The ancient part of the town is surrounded by a dilapidated wall with towers. The entrance is by a single gate, once defended by an Arab castle, now in ruins. The modern portion is outside the walls, and is well and handsomely built. There are two colleges and several schools, convents, chapels, and hospitals. It has manufactures of woollen and linen fabrics, and earthen ware, and a trade in wine, wheat, cattle, oil, honey, &c.

CASTROGIOVANNI, or **Castro Giovanni** (anc. *Enna*, from one form of the name of which, *Castrum Enna*, corrupted by the Arabs to *Cassar Janna*, the modern designation comes), a city of Sicily, in the province and 13 m. N. E. of Caltanissetta; pop. about 15,000. It is situated on the level summit of a precipitous

and rocky height in the centre of the island, 4,000 ft. above the sea, and is the highest inhabited site in Sicily. Its situation rendered it in ancient times one of the strongest natural fortresses in the world, and during the middle ages it bore the name of *V Inespugnabile* (the Impregnable). The appearance of the mod-

Castrogiovanni.

ern town is mean and wretched; the dwellings are generally dilapidated, and have a dingy and stained appearance largely attributable to climatic influences. The old feudal fortress of Enna, erected in the 13th century by Frederick II. of Aragon, is the chief edifice. The height of Enna was the fabled birthplace of Ceres, and the site of her most famous temple. About 5 m. distant is the lake of Pergusa, where Proserpine, according to the poets, was carried off by Pluto. During the first servile war, about 100 B. C., the insurgent slaves made Enna their headquarters.

CASTRUCCIO-CASTRACANI, a leader of the Ghibellines in Italy, born in Lucca about 1282, died Sept. 3, 1328. He was a member of the noble Antelminelli family, and in childhood was banished with his relatives by the Guelphs. His military exploits in France, England, and Lombardy led to his being placed at the head of the Ghibellines in Lucca; but his ally, Ugucione de la Faggiola of Pisa, after having aided him in putting down the Guelphs, sacked Lucca, and put him in prison, from which he was released by the people rising against Ugucione and expelling him and his followers. Castruccio was elected governor of Lucca, and during the 15 years of his administration was engaged in warfare with Florence, with a view of establishing his supremacy over the Ghibellines of Tuscany. Louis IV., emperor of Germany, rewarded his services by investing him with

the rank of duke of Lucca, count of the Lateran, and Roman senator; but Pope Boniface VIII. resented his victories over the Guelphs by excommunicating him shortly before his death. Nicolò Negrini (Modena, 1496), Wieland (Leipsic, 1779), and Manuzzi (Rome, 1820) have published works relating to him; but the most celebrated is that by Machiavelli (French translation by Dreux du Radier, *La vie de Castruccio-Castracani*, Paris, 1753).

CASVEEN. See **CASBIN**.

CASWALL, Henry, an English clergyman and author, born at Yateley, Hampshire, in 1810, died in January, 1871. He was the son of a clergyman, received his early education in England, and subsequently went to the United States. He received the degree of B. A. at Kenyon college, Ohio, in 1830, and that of M. A. in 1834, and was ordained in 1837 by the bishop of Indiana. He was engaged as minister and professor of theology in the United States and Canada till 1842, when he returned to England. The disabilities of his American ordination were removed by a private act of parliament, and in 1848 he became vicar of Figheldean, Wiltshire, and subsequently proctor in convocation for the diocese of Sarum, and prebendary of Salisbury cathedral. In 1854 he received the degree of M. A. from the university of Oxford, and on revisiting the United States in the same year that of D. D. from Trinity college, Hartford. He published

"America and the American Church" (1839), "City of the Mormons" (1842-'3), "Scotland and the Scottish Church" (1853), "The Western World Revisited" (1854), and other works.

CASWELL, a N. county of North Carolina, bordering on Virginia; area, 400 sq. m.; pop. in 1870, 16,081, of whom 9,494 were colored. It is intersected by Hycotee river and County Line creek, affluents of Dan river. The surface is undulating, and the soil fertile. The Richmond, Danville, and Piedmont railroad crosses the N. W. corner. The chief productions in 1870 were 80,597 bushels of wheat, 237,257 of Indian corn, 93,646 of oats, and 2,262,053 lbs. of tobacco. There were 1,543 horses, 2,126 milch cows, 1,984 other cattle, 2,765 sheep, and 9,175 swine. There were 5 manufactories of carriages and wagons, 2 of iron castings, 2 of chewing tobacco, and 9 flour mills. Capital, Yanceyville.

CASWELL, Richard, an American revolutionary general and statesman, born in Maryland, Aug. 3, 1729, died Nov. 20, 1789. In 1746 he removed to North Carolina, where in 1754 he became a member of the colonial assembly, in which he continued to hold a seat till 1771. He was then chosen speaker of the house of commons, and colonel of the county militia, and at the outbreak of the revolution identified himself with the patriots. He soon after became treasurer of the state. In 1776, in command of a regiment of minute men, he defeated the loyalists at Moore's creek, and for this service was appointed brigadier general. For three years he was president of the provincial congress which framed the state constitution, under which he was elected the first governor. He was engaged in the disastrous battle of Camden in 1780, became comptroller general of the state in 1782, and was again elected governor in 1784, to which office he was twice reelected. In 1787 he was a delegate to the convention assembled at Philadelphia for the formation of the federal constitution; in 1789 he was speaker of the state senate, and he was subsequently one of the convention by which the federal constitution was ratified in North Carolina. He was presiding in the senate when he was struck with fatal paralysis.

CAT, a general name for animals of the genus *felis* (Linn.), which comprises about 50 species of carnivorous mammalia, the characters of which are closely assimilated, and at the same time widely different from other genera. It is characterized by six incisor teeth above and below; two canine teeth in each jaw, powerful and formed for tearing; molar or cheek teeth, four in the upper jaw and three in the lower, thin, pointed, and wedge-shaped, formed for cutting. The head is large, round, and wide; the eyes have the pupil often oblong; the tongue has strong horny papillæ, directed backward. The feet are formed for walking; the toes are five in number on the fore feet and four on the hind feet, armed with strong, sharp, and hooked claws, retracted when the animal

walks. The intestines are very short, as in all animals living almost exclusively on animal food. The animals composing this genus (which includes the lion, tiger, panther, &c.) are the most powerful and ferocious of all predatory quadrupeds, as the eagles and birds of prey are among the feathered tribes. The different species are distributed over every portion of the globe, with the exception of Australia and the South Pacific islands; but the most formidable are found in the warmest climates; no species has been discovered common to the old and the new world. The favorite resorts of these animals are the thick forests of the tropics, where they lie concealed during the day, and prowl at night in search of prey; the more northern and smaller species prefer rocky and well wooded situations. The cats hunt a living prey, which they secure by cunning and watchfulness, springing upon their unsuspecting victims from an ambush, or stealthily crawling up to them. Some species, as the leopard and jaguar, pursue their prey into trees. The cougar lies in wait on a branch or overhanging rock, and falls upon animals passing beneath. Their aspect is ferocious, their instincts bloody, and their strength great; even their voice has something in it harsh and terrible. The anatomical structure of the cats is indicative of great strength and activity; the jaws are very powerful, bearing teeth shaped like wedges, thin and sharp, requiring but little force to cut through the flesh on which they feed; the structure of the joint admits of no lateral motion, and the whole force of the immense temporal and masseter muscles is exerted in a perpendicular or cutting direction. To assist in tearing their food, the surface of the tongue is covered with numerous horny papillæ; these may be felt, on a small scale, on the tongue of the domestic cat; the tongue is rather an organ for removing muscular fibres from bones, and for retaining flesh in the mouth, than an organ of taste. The neck, shoulders, and fore limbs display a remarkable muscular development; the lion can drag away with ease cattle and horses which it has killed; a single blow of the fore limb of a Bengal tiger has been known to fracture a man's skull. The mechanism by which their claws are retracted and prevented from being blunted during walking is as follows: the claw itself is supported on the last bone, which consists of two portions united to each other at nearly a right angle; the articulation is at the upper end of the vertical portion, while the flexor tendons are attached to the other portion; the action of these muscles causes the whole bone to move through an arc of 90° round the end of the second bone. In the state of rest the claw is kept retracted by a slip of the extensor muscle, and by elastic ligaments; in the state of action, the strong tendon of the flexor, with its circular sweep, protrudes the claw with prodigious power.—The domestic cat is generally believed to have sprung from the Egyptian cat (*felis maniculata*, Rüppell), a native of the north of Africa.

This species is 2 ft. 5 in. long, of which the tail measures 9 in.; the height at the shoulder is 9½ in.; in size it does not differ from the domestic cat. The color above is an ochry gray, with a darker line along the back; beneath, grayish white; on the forehead are eight slender black lines, running forward to the upper part of the neck; the cheeks, throat, and front of the neck are pure white; two lines of an ochre-yellow color, one from the outer corner

Egyptian Cat (*Felis maniculata*).

of the eye, and the other from the middle of the cheek, meet under the ear, and two rings of the same color encircle the white of the neck; the limbs have five or six blackish semi-circular bands; the heels and wrists are black; the tail is slender, and has two dark rings at the tip. There is no doubt that this species is the original of the domestic cat of the ancient Egyptians, as is shown by the representations of cats on their monuments, by mummies, and by the skeletons found in their tombs. It may be a question whether this domesticated species was transferred by them to the ancient nations of Europe. There certainly is often met with, in modern times, a grayish white cat possessing the most striking resemblance to the Egyptian species; others of our domestic cats resemble the wild species of Europe. It is probable therefore that, as with all our domestic animals, different nations have domesticated different small kinds of native cats, which have produced, by the intermixture of their closely allied species, the numerous varieties now observed. At the same time it should be remembered that the whole genus *felis* is susceptible of considerable variation; slight variety of color, therefore, does not necessarily imply diversity of origin. Temminck and Rüppell are of the opinion that the *F. maniculata* is the species from which our domestic cat has sprung; before them most naturalists believed that the wild cat of Europe was the original stock; it is altogether probable that the domesticated species has been crossed in many instances by the wild cat, as shown by the short legs and thick short tails of some varieties. All the small species of cats might be easily domesticated, though the common Egyptian species seems to be the only one generally employed in household economy. The domestic cat readily returns to a wild state; neglect,

insecurity of their young, or favoring circumstances, drive or tempt them to the woods, where they prowl and hunt, and breed, in the manner characteristic of the genus. Cats, though they prefer flesh, will eat bread, fish, insects, and almost anything that is eaten by man. As a general thing, they have a great dislike to water, and will rarely enter it for the purpose of catching fish, of which they are extremely fond. They are capable of very strong attachment to man, and to animals reared with them. Among the most remarkable varieties of the domestic cat are the Maltese or Chartreuse cat, of a bluish gray color; the Persian cat, with long white or gray hair; the Angora cat, with very long and silky hair, generally of a brownish white color; and the Spanish or tortoise-shell cat, the most beautiful of all. In Cornwall and the Isle of Man a breed of cats without a tail is quite common, analogous to a similar and more common breed

Manx Cat.

of dogs.—The common wild cat (*F. catus*, Linn.) is the only animal of the genus that inhabits the British islands, where it is still not uncommon in the wild districts of Scotland and Ireland; it is found in the wooded tracts of the European continent. The length of the wild cat is 33 in., the tail being 11 in. The fur is long and thick, but not shaggy; the color varies from a yellowish to a blackish gray, darkest on the back, where it forms a line, diverging into four on the neck and head; the sides are brindled with broad, dark, but indistinct bands; the legs have two or three black bars,

Wild Cat (*Felis catus*).

running transversely upward; the tail is thick, with black rings, indistinct toward the base, and a black tip. The wild cat is an active

climber; its food consists of small animals and birds; its depredations among game are frequently very great. There are no long-tailed wild cats in North America; the animal called wild cat here is a species of lynx. (See LYNX.) The catamount is the cougar of authors. (See COUGUAR.) There are several small species of cats in the East Indies: the Sumatran cat, *F. minuta* (Temm.) and *F. Javanensis* (Horsf.); the Bengal cat, *F. Bengalensis* (Desm.); Diard's cat, *F. Diardii* (Desm.); and the Nepal cat, *F. Nepalensis* (Horsf.).

CATACOMBS (Gr. *κατά*, downward, and *κύμβος*, a hollow place), subterraneous places for burying the dead. The catacombs of Egypt, from their vast extent and elaborate decorations, both of architecture and painting, are perhaps more remarkable than any others. The entire chain of mountains in the neighborhood of Thebes is mined by an immense number of these subterranean tombs. Those of the Theban kings, originally 47 in number, are the most ancient of all, some having been begun 4,000 years

ago. Most of them have been defaced, but a few still exist to bear witness to their pristine magnificence. They occupy a deep ravine, flanked by the bed of a torrent in the centre of the mountain Libycus, and, lying some 6,000 to 7,000 paces from the banks of the Nile, were reached by an artificial passage. Proceeding along the valley, the visitor discovers openings in the ground, with a gateway in a simple square frame, each gateway being the mouth of a gallery leading to the royal sepulchre. Forty paces within is another gateway opening to a second gallery 24 ft. in length, and on each side of this are small chambers. A third gallery succeeds, communicating with a chamber 18 ft. square, and from this is an entrance to another gallery 64 paces in length. This in its turn connects with several small apartments, beyond which lies a saloon 20 ft. square, containing the royal sarcophagus. The whole extent of excavation in this single tomb is upward of 225 paces. All the sarcophagi of the kings have long since been violated, and the bodies

The Catacombs of Thebes, Egypt. (From a Photograph.)

destroyed, doubtless for the sake of plunder; but M. Denon, the French traveller, found the fragments of a mummy in one of the royal tombs. Robbed as they have been, these tombs still preserve their wonderful paintings, after in some cases a lapse of 4,000 years. The more costly of the catacombs are covered in the whole extent of their interior by hieroglyphics and pictures, generally in fresco; and in all, unless wantonly injured by the Arabs, the colors are as fresh as if laid on but yesterday. The catacombs of the opulent Thebans were lower on the mountain than the royal sepulchres, and in proportion to the extent of their excavations they are more or less richly decorated, the hues of the paintings are brilliant, and the sculptures elegantly defined. Innumerable subjects are displayed in these tombs, one chamber being devoted to warlike representations, and another to husbandry or agriculture. Every ordinary occupation or amusement is exhibited, hunting, fishing, feasting, &c. Many of the figures are colored yellow on a blue ground,

exhibiting homage paid to monarchs, executions, religious or funeral processions, and in short every phase of human life. In some of the scenes gangs of African negro slaves, colored black, and accurately drawn in all leading characteristics, such as thick lips and woolly hair, are represented. In a group of a double file of negroes and Nubians, bound, and driven before the chariot of Rameses II., at Ipsambul, are delineated with perfect accuracy all the characteristics of the modern Ethiop. The paintings in the Egyptian catacombs also exhibit figures of colossal or pigmy size, as well as hawk-headed and fox-headed deities. The complete history of the ancient Egyptians may be read in these paintings, as every action of their lives is represented, with accompanying furniture, even down to the playthings of infants. "The Manners and Customs of the Ancient Egyptians," by Sir Gardner Wilkinson (5 vols., London, 1847), contains many hundreds of drawings and colored plates directly copied

from these extraordinary frescoes, and makes the reader so intimately acquainted with the daily life of an extinct people, that he seems actually to dwell among them. The catacombs for the poor were limited in space, rude in construction, and unadorned. In consequence, the mummies were packed together as closely as they could be laid, tier on tier, leaving a narrow passage between the walls of bodies.—For nearly the whole period of the Christian era have the Roman

Catacombs of St. Thraso and St. Saturninus, Rome.

catacombs attracted the interest of Christians, more especially during the last few centuries. Connected as they were with the trials of the early martyrs of the church, their exploration and history has ever proved one of the favorite branches of research. Many of them are of great antiquity, having been originally quarries hewn long before the Rome of Romulus and Remus was founded, and so extended in the course of time, that every one of the seven hills on which the city stood was perforated and honeycombed by passages, dark galleries, low corridors, and vaulted halls, where sunshine never enters. The light and soft nature of the material to be quarried greatly facilitated the work, and allowed the workmen to shape their shafts and galleries as they pleased; the excavations being made in the soft volcanic *tufa* and *pozzolano*, another volcanic substance even softer. As the extent and wealth of the city increased, new quarries were continually opened, even miles from the banks of the Tiber, and continued to be sought through the reigns of the Cæsars, until the empire began to decline, and old edifices were resorted to as materials for new ones. None of the ancient writers have left any account of the uses of these recesses when they were no longer quarried; but Horace, speaking of the caverns under the Esquiline hill, says: "This was the common sepulchre of the miserable plebeians." During the time of the persecutions of the Christians, commencing with that under Nero, and followed by those of Domitian, Trajan, Hadrian, Severus, Maximinus, to what is called the 10th and last persecution, which began in A. D. 303, under Diocletian, the catacombs were crowded with those for whom there was no

safety in the face of day. It is conjectured that many of these sufferers were aided in obtaining secure hiding places by the workmen in these caverns, who were well acquainted with their intricacies, and who became themselves early converts to the new faith. Some modern writers, however, maintain that though the quarries were used to some extent as sepulchres, it is yet evident that the greater part of the catacombs were originally constructed as places of interment for the dead. They are found in every direction outside the walls of the city, to the number of about 60 in all. They are mostly within a circuit of 3 m. from the walls, the furthest, that of St. Alexander, being 6 m. distant. Each catacomb forms a network of passages or galleries, intersecting each other generally at right angles, but sometimes diverging from a centre. These galleries are usually 8 ft. high by 3 or 5 ft. wide. The graves are in tiers on the sides, and when undisturbed are found closed with marble slabs or tiles, on which are often inscriptions or Christian emblems. It is calculated that the entire length of the catacombs is not less than 580 m., and that they contain about 6,000,000 bodies. It was not until the year 1377, when the papal seat, which for nearly 70 years had been at Avignon, was restored to Rome, that the catacombs appear to have attracted any serious attention from the government or the clergy. This was doubtless owing to the frightful state of society, which for some centuries after the extinction of the Western empire rendered Rome little better than a robbers' stronghold, and finally forced the pontiff to flee from the Tiber and seek an asylum on the banks of the Rhône. At this period the catacombs, from having been the habitations of persecuted Christians, were thronged with outlaws and assassins; but as the papal authorities acquired strength, many of them were driven out and the entrances to many of their retreats were closed. About 1535, under Pope Paul III., some few of the most remarkable of the crypts were explored, cleared, and lighted by lamps. A deep interest in subterranean Rome having thus been awakened, Father Bosio, a humble priest, but an enthusiastic antiquary, spent more than 30 years of his life in digging and groping in the catacombs; he cleared the way into some of the innermost recesses, which had been blocked up for centuries, and made drawings of the ancient monuments, inscriptions, paintings, sculptures, lamps, vases, &c., found underground. He did not live to see his work published, as he died (1629) while writing the last chapter; but it appeared in 1632, edited by Father Severani, and under the title of *Roma sotterranea*. It was translated into Latin by Father Aringhi, and still forms the most important work on the Roman catacombs. He was followed by Father Boldetti, who also spent more than 30 years in his subterranean research, and published in 1720 a folio volume, entitled "Observations on the

Cemeteries of the Holy Martyrs and Ancient Christians of Rome." This work is exceedingly valuable. These two enthusiastic and meritorious priests have been succeeded by such investigators as Bottari, Marangoni, Lupi, Fabretti, Filippo, Buonarrotti, Allegranza, &c. Seroux d'Agincourt is one of the most distinguished authorities of modern times; he went to Rome in the latter part of the last century to study Christian archæology and remain there for six months, but he became so interested in his inquiries that he stayed nearly 50 years. His great work, *Histoire de l'art par les monumens, depuis sa décadence au 4^e siècle jusqu'à son renouvellement au 16^e*, treats of the catacombs with profound learning and discrimination. Among more recent works is the magnificent one published at the expense of the French government, *Les Catacombes de Rome*, by Louis Perret (Paris, 1853); and in English, those of the Rev. Spencer Northcote, "The Roman Catacombs" (London, 1859), and "Roma Sotterranea" (London, 1869). The distinguished Roman antiquary, the chevalier de Rossi, is preparing for publication a complete collection of all the Christian inscriptions, amounting to upward of 11,000, of which one vol. folio appeared in 1861. The same author is engaged upon a general work under the title of *Roma sotterranea cristiana*, of which vol. i. appeared in 1866. Among other recent writers of importance on the Roman catacombs may be mentioned Maitland, "Church in the Catacombs;" Kip, "The Catacombs of Rome;" Schaff, Rémusat, Jehan, Martigny, and Bouix. Under Pius IX. their exploration has been carried on with much intelligence and energy, and has resulted in many interesting and valuable discoveries. A full statement of these researches since November, 1871, is given in De' Rossi's *Bollettino di Archeologia*, new series, No. IV. When Bosio's discoveries were made known Pope Clement VIII. took the catacombs under his special protection, and decreed excommunication and severe corporal punishment against any one who should enter them without

leave, or remove from them the least object whatsoever. So highly were the virtues of the Christian martyrs esteemed, that personages of the highest distinction were buried in the catacombs, and were happy if they thought that after their death such honor should be paid to their remains. Among illustrious men thus entombed were the popes Leo I., Gregory the Great, Gregory II. and III., and Leo IX.; and the emperors Honorius, Valentinian, and Otho II.—The catacombs of Naples have larger and higher chambers and galleries than those of Rome; they are excavated in the volcanic tufa in the face of the hill of Capodimonte, forming a long series of corridors and chambers, arranged in three stories communicating with each other by steps. The only entrance now open is that of the church of San Gennaro. Their construction has given rise to many speculations among the antiquaries of Naples, but is now generally ascribed to the colonists from Greece. Subsequently they were used by the early Christians for purposes of sepulture as well as of worship. St. Januarius and other martyrs were interred here. In the middle of the 17th century they were made the burial place of the victims of the plague, and at the beginning of this century several bodies were found by Domenico Romanelli.—The catacombs of Syracuse form an immense subterranean town, with innumerable tombs cut out of the solid rock, containing the dead of all ages, nationalities, and creeds. They, also, were converted by the early Christians into places of refuge from persecution. The entrance to them is under the church of San Giovanni. The catacombs of Malta are of small extent, but in good preservation. They seem to have been used for a place of worship as well as of sepulture.—The so-called catacombs of Paris were never catacombs in the ancient sense of the word, and not devoted to sepulchral purposes until the year 1784, when the council of state issued a decree for clearing the cemetery of the Innocents, and for removing its contents, as well as those of other graveyards, into the

The Catacombs of Paris.

quarries which had existed from a remote period beneath the southern part of Paris, and by which the observatory, the Luxembourg, the Odéon, the Val de Grâce, the Panthéon, and the streets La Harpe, St. Jacques, Tournon, Vaugirard, and many others were completely undermined. Some excavations having taken place, a special commission was appointed to direct such works as might be required. Engineers and workmen were immediately employed to examine the whole of the quarries, and prop the streets, roads, churches, palaces, and buildings of all kinds which were in danger of being engulfed. The plan of converting the quarries into catacombs originated with M. Lenoir, lieutenant general of the police, and every preparation was made by sinking a shaft, propping up the cavities, and walling off various portions for receiving their future contents. The ceremony of consecrating the catacombs was performed with great solemnity on April 7, 1786, and on the same day the removal from the cemeteries began. This work was always performed at night; the bones were brought in funeral cars, covered with a pall, and followed by priests chanting the service of the dead, and when they reached the catacombs the bones were shot down the shaft. Such tombstones, monuments, &c., as were not claimed by the families of the deceased, were arranged in a field near the entrance of the shaft, and among these relics was the leaden coffin of Mme. de Pompadour. As other cemeteries were suppressed, the bones from them were removed to this general deposit by order of the government. The catacombs served also as convenient receptacles for those who perished in popular commotions or massacres. At first the bones were heaped up without any kind of order, except that those from each cemetery were kept separate; but in 1810 a regular system of arranging them was commenced, and the skulls and bones were built up along the wall. The principal entrance to the catacombs is near the *barrière d'Enfer*, but for some years past admission into them has been strictly interdicted, on account of the dangerous state of the roofs of the quarries. From the entrance a flight of 90 steps descends to the catacombs; a series of galleries are then seen branching in various directions, and several hundred yards from the steps is the vestibule, of octagonal form, and over the door is the following inscription: *Has ultra metas requiescunt beatam spem spectantes.* The vestibule opens into a long gallery lined with bones from the floor to the roof; the arm, leg, and thigh bones are in front, closely and regularly piled together, and their uniformity is relieved by three rows of skulls at equal distances. Behind these are thrown the smaller bones. This gallery conducts to several rooms resembling chapels, lined with bones variously arranged. One is called the "Tomb of the Revolution," another the "Tomb of Victims," and contain the bodies of those who perished either in

the early period of the revolution, or in the massacres of September. Calculations differ as to the number of bones collected in this vast charnel house, but it is estimated to contain at least the remains of 3,000,000 human beings. A map of the catacombs and quarries under the city has been drawn up by the order of the municipal authorities. These excavations are 3,000,000 square metres in extent.

CATAHOULA, an E. central parish of Louisiana, bounded E. and S. E. by Tensas and Black rivers, S. and S. W. by the Saline; area, 1,970 sq. m.; pop. in 1870, 8,475, of whom 4,083 were colored. Catahoula lake is in the S. part. It is watered by the Washita, Tensas, Black, and Little rivers, several of which are navigable by steamboats through the parish and on its borders. Near the Washita river the surface is partly occupied by hills. The soil in some parts is fertile, and lies upon a bed of sandstone. The chief productions in 1870 were 76,165 bushels of Indian corn, 6,528 of sweet potatoes, and 8,872 bales of cotton. There were 1,449 horses, 3,062 milch cows, 7,360 other cattle, 1,751 sheep, and 12,372 swine. Capital, Harrisonburg.

CATALANI, Angelica, an Italian singer, born at Sinigaglia about 1785, died in Paris, June 13, 1849. When only seven years old she attracted general attention by the remarkable power and purity of her voice. People went in such numbers to the convent of St. Lucia, near Rome, where she received her education, to hear her, that the police had to check the pressure of the crowd. In 1802 she made her début in opera in Rome with marked success, and afterward fulfilled engagements in the principal cities of Italy. She next appeared in Italian opera in Lisbon, Madrid, Paris, and London, where her singing created the greatest enthusiasm. In 1815 she returned from England to Paris, where for about four years she was connected with the management of the Italian opera in coöperation with her husband, M. de Valabrègue, formerly a captain in the French army. In this enterprise she was not successful. Her clear, powerful voice electrified the English, especially in "God save the King;" but her influence over continental audiences was not so great. She sang in Germany, Denmark, Sweden, Poland, and Russia, returning also occasionally to her native country, and afterward again made her appearance in Paris, but without meeting with great success. In 1830 she withdrew from the stage, and devoted herself at Florence to the education of her three children, and established a free singing school for girls. In June, 1849, during the revolution in Tuscany, she went to Paris with her daughters, but almost immediately after her arrival she fell a victim to the cholera. She had amassed a large fortune.

CATALEPSY (Gr. *κατάληψις*, seizure), a non-febrile affection, occurring in paroxysms, and characterized by a sudden deprivation of intelligence, sensation, and voluntary motion.

The disease is so seldom met with that some well known writers have doubted its existence, and have attributed the recorded cases to imposture. Bourdin (*Traité de la catalepsie*, Paris, 1841), who collected all the recorded facts within his reach, was able to unite but 38 well characterized observations. The attack is often preceded by headache, confusion of mind, loss of memory, &c.; more commonly, however, nothing of the kind has been noticed. During the paroxysm the patient retains the position and expression of countenance he had at the moment of the seizure; the face is commonly pale, sometimes slightly flushed; the pupils are dilated, but contract on exposure to a strong light; the limbs can be moved with the exertion of a little force, and retain the new position which may be given them; if the patient is standing and is pushed, he makes no effort to save himself; if placed in a painful and constrained attitude, it is retained during the paroxysm. The unvarying, motionless attitude and fixed expression give a strange and corpse-like look to the sufferer. The duration of the attack is variable; sometimes it lasts but a few minutes, sometimes 12 or 14 hours; cases are recorded in which it has been prolonged to 20 or even 30 days. Many cases occur in which the attack is less characteristically marked, or in which a portion only of the symptoms is present. Although deprived of speech and voluntary motion, the patient is more or less conscious of what is passing around him. In Duncan's "Medical Commentaries," a case is related of a woman who in this state of partial catalepsy was taken for dead, and who was perfectly conscious of what was occurring around her, while her body was being laid out and prepared for interment. In ecstasy, a disease allied to catalepsy, and which by imperceptible degrees passes into it, the patient is insensible to everything about him, while the mind is absorbed in some one object or train of ideas; the muscles are either relaxed or in a state of almost tetanic rigidity, while the patient speaks and sings, perhaps with greater readiness and ease than in his natural condition. This condition is frequently occasioned in nervous and hysterical persons by religious excitement, and is often produced in a similar class of persons by animal magnetism. It is one much more commonly assumed by impostors than true catalepsy. Both catalepsy and ecstasy seem to be closely allied to hysteria; they occur for the most part in young females of nervous habit, and both the one and the other often commence or terminate in it; occasionally, however, as is likewise the case with some of the more ordinary manifestations of hysteria, they have their origin in serious disease of the brain. The age and history of the patient will help the intelligent physician to discriminate such cases. Some strong moral excitement is generally the immediate cause of the disease, but when it is already formed, or when the predisposition to it is very strong, a most trifling cause—a sud-

den noise, the surprise of an unexpected visit, &c.—may induce a paroxysm. In itself the disease is never fatal, and morbid anatomy throws no light upon it. In regard to the treatment, in the interval between the paroxysms means should be employed to improve the general health and give tone to the nervous system. During the paroxysm the feet may be immersed in a mustard foot bath and cold applications made to the head; of these, where it can be borne, the cold douche is best.

CATALONIA (Span. *Cataluña*), a maritime division of Spain, on the Mediterranean, lying between lat. 40° 30' and 42° 51' N., and lon. 0° 15' and 3° 21' E.; area 12,504 sq. m.; pop. in 1867, 1,744,032. It is bounded N. by the Pyrenees, E. by the Mediterranean, S. by Valencia, and W. by Aragon. The coast line is about 240 m.; the principal ports are Barcelona, Rosas, and Tarragona, connected by railway with other parts of the Spanish coast and with the interior. Catalonia is divided into the provinces of Barcelona, Tarragona, Lérida, and Gerona. The face of the country is much broken by spurs of the Pyrenees. Some of these mountain ranges diverge toward the Mediterranean; others, of which the chief is the Sierra de la Llena, pursue a S. W. direction to the Ebro, and form a watershed in which 26 rivers have their rise, and flow either westward to the Ebro or eastward to the sea. The principal of these streams are the Segre, a tributary of the Ebro, the Noguera Pallaresa and Noguera Rivagorzana, tributaries of the Segre, the Llobregat, Francoli, Tordera, Ter, and Fluvia. None of these are navigable to any great extent. The general grade of the country is a descent from the mountain altitudes of the Pyrenees to the plateaus of upper Catalonia, and thence to the plains which skirt the Mediterranean. Most of the inland mountains are of granitic formation; those near the coast are limestone. Traces of volcanic origin are found especially in the vicinity of Barcelona. Valleys of remarkable fertility intersect the mountains. Such are the plateau of Urgel, and the valleys of Cerdaña, Tarragona, Valls, La Selva, Igualada, Cervera, Ampurdan, and Lérida. About half the surface is susceptible of cultivation, the rest consisting of rocks, barrens, and woodlands. Forests of beech, pine, elm, and cork are found in the mountainous districts. Iron, copper, lead, and manganese are found; coal is met with in quantity, but it has been turned to little account; crystals, amethysts, topaz, jasper, and marble occur; and there are hot and mineral springs in various parts. Of alum, nitre, and rock salt the supplies are inexhaustible; at Cardona is a mound of pure salt, 500 ft. in height and 3 m. in circumference. Near Olot, 55 m. N. of Barcelona, is a remarkable district of extinct volcanoes. Montserrat is a single and precipitous mountain, composed of a number of conical hills heaped in confusion over one another, and broken into fantastic shapes of parti-colored

limestone. The climate of Catalonia varies with the altitude of the region, but is in general temperate, the heat being moderated by sea or mountain breezes. The country is considered healthy, the interior more so than the coast. Although the orange, lemon, almond, olive, and fig grow on the plains, they are produced in less abundance than in other districts of Spain; but orchard fruits ripen in perfection. The vine is exceedingly productive, and wine is the staple export. Agriculture is further advanced in Catalonia than in any other part of Spain. This is partly owing to the industrious character of the people, partly to the nature of the soil, and in a considerable measure to the more equitable tenure of land. All kinds of grain are cultivated and consumed at home, leaving no surplus for export. The soil is usually a light loam, easily worked. Irrigation being necessary to make it productive, it is found profitable to grow wine and oil in preference to breadstuffs. Flax, hemp, dyestuffs, honey, and wax are produced in considerable quantity. Nuts and cork are important articles of export. Silk growing is but little attended to, and the raising of wool and cattle is of comparatively small extent. Since the liberation of the South American provinces, the commerce of Catalonia has greatly fallen off. The shoe trade, calico weaving, and ship building, which were formerly important branches of industry, have almost ceased to exist. Activity, however, continues in the fabrication of silks, velvets, ribbons, hosiery, linen and laces, leather, hats, cordage, brandy, cannon and small arms, glass, soap, hollow ware, and copper utensils. These are exported to France, England, and Holland, in exchange for textiles, jewelry, codfish, herring, and other articles of consumption. Along the coast a large proportion of the inhabitants are engaged in the fisheries, and there are few good harbors.—Catalonia under the Romans originally belonged to Hispania Citerior, but in the time of Augustus it formed part of the Provincia Tarraconensis. Caesar made Tarragona the centre of his operations during his first war in Spain, and it was the chief place of residence of the generals who succeeded him. Early in the 5th century the province was occupied by the Goths and Alans, and its name is supposed by some to be derived from a combination of the names of these two nations, and to have been at first Gothalanía. In 712 it was occupied by the Moors, who held it only a few years; and in 788 it formed part of the vast empire of Charlemagne. His successors, however, maintained only a nominal sovereignty over it, the real power being in the hands of several counts among whom its territory was divided. In the early part of the 12th century the most powerful among these was Raymond Berenger, count of Barcelona, who succeeded in reducing all the others to subjection. In 1137 he married Petronilla, heiress of the throne of Aragon, and Catalonia was

united to that kingdom. It afterward rebelled several times, but toward the end of the 15th century it became an integral part of the Spanish empire, though still retaining many of its peculiar rights and privileges. Philip IV. having attempted to take these away, it revolted in 1640, and in 1641 gave itself up to Louis XIII. of France. It was restored to Spain in 1659, and again occupied by the French from 1694 to 1697. During the war of the succession it supported the archduke Charles. After the treaty of Utrecht in 1713, by which the right of Philip V. to the throne of Spain was acknowledged, Catalonia continued for a year to resist, but was subdued and deprived of its ancient rights and liberties in 1714. The French occupied it in 1808, after having been strongly resisted by the inhabitants, and again evacuated it in 1813. In 1823 it offered a staunch resistance to the restoration of absolutism under Ferdinand VII. Its rural inhabitants have always been warm supporters of the Carlist party, and it is at present (1873) the chief scene of their operations. Barcelona, on the other hand, has made itself equally conspicuous by its republican spirit.

CATALPA, a genus of plants belonging to the natural order *bignoniaceæ*, whose generic characteristics are a two-parted calyx, a bell-shaped, swelling corolla, five stamens, two of which only are fertile, a long, slender, cylindrical pod, and broadly winged seeds. There are three species, all of them trees, with simple leaves and paniced, terminal flowers. The *C. syringifolia* (Loud.) is indigenous in the southern parts of the United States, and is cultivated as an ornamental tree in most of the cities of the northern states. It is distinguished by its

Catalpa syringifolia.

silver-gray, slightly furrowed bark, its wide-spreading head, disproportioned in size to the diameter of its trunk, the fewness of its branch-

es, and the fine pale green of its very large heart-shaped leaves. Its showy flowers are white, slightly tinged with violet, and dotted with purple and violet in the throat. They are succeeded by pods, often a foot in length, which hang till the next spring. In its natural locality, this tree frequently exceeds 50 ft. in height, with a trunk from 18 to 24 in. in diameter; but in Massachusetts it dwindles to a mere shrub, and is often killed by the frost. It is cultivated in gardens in England, and on the continent of Europe. One of the oldest and largest catalpas in England is in Gray's Inn gardens, and is said to have been planted there by Lord Bacon. In parts of Italy and in the south of France the catalpa is planted as a wayside tree, and along the avenues to country villas. It may be propagated either by seeds or from cuttings of the root. It usually reaches the height of 20 ft. in 10 years, soon after which it begins to blossom. The wood is light, of a very fine texture, susceptible of a brilliant polish, and often used in cabinet-making.

CATALYSIS (Gr. *καταλύειν*, to resolve), in chemistry, a name given by Berzelius to an obscure class of phenomena of which little is positively known. He says: "Certain bodies exert, by their contact with others, such an influence upon these bodies, that chemical action is excited; compounds are destroyed or new ones are formed, although the substance by which these actions are induced does not take the slightest part in their changes." It is now thought that this catalytic force is purely imaginary; most of the phenomena which have hitherto been referred to its agency being occasioned by several different causes, which often admit of being distinguished from each other, and which may be explained by the active operation of other known forces.

CATAMARCA. I. A province of the Argentine Republic, lying between lat. 25° and 29° S., and lon. 66° and 69° W., and bounded N. by the province of Salta, E. by Tucuman and Santiago, S. by Rioja, and W. by the Chilian Andes; area, 35,000 sq. m.; pop. in 1869, 79,551, most of whom, with the exception of 411 foreigners, are mestizos and Indians of pure blood, descendants of the once numerous and formidable tribe of the Calchaquis. Catamarca, the most picturesque of all the Andine provinces, is intersected by lofty mountain chains, the highest and most generally known of which is the Sierra de Aconquija, nearly 17,000 feet high. Watercourses are very numerous, but the only one deserving the name of river is the Santa Maria. Most of the streams become dry in summer, but in winter they swell to enormous proportions and commit great ravages. Some of the elevated plains are entirely deprived of water and all moisture, being sandy deserts; while others are periodically inundated, and when the water subsides are covered with immense crystallized cakes of salt, which are cut into blocks of about 24 inches square, and transported on llamas to

the neighboring provinces. The principal other minerals are gold and silver, rich mines of which were formerly worked, but afterward abandoned, and copper, which is extracted in large quantities. The vegetable productions comprise nearly all the grains, fruits, and vegetables of tropical and temperate climates, apples being especially plentiful. Cotton, said to be the finest in the world, is raised, though much less extensively than formerly; and there are vast forests yielding many kinds of valuable timber. The inhabitants are mainly occupied in agriculture, the manufacture of earthenware, weaving of ponchos and horse covers, and other fabrics of llama, vicuña, and sheep's wool, and also of alpaca. Large herds of these animals, and likewise of horned cattle, asses, and mules, are raised for export. Catamarca also exports raisins, tolerable wine, brandy, hides, leather, tobacco, red pepper, anise and cummin seeds, cochineal, copper in bars, &c. **II.** A city, capital of the province, situated in its centre, in a valley formed by the Ambato mountains, 725 m. N. W. of Buenos Ayres; pop. about 6,000. The streets are well laid out, and the houses, although extremely diverse in size, are strongly built and nearly all whitewashed, and surrounded by orange trees. The country immediately surrounding it is highly cultivated. The chief occupation of the inhabitants is the manufacture of woollen and silk hats. There are several flour mills and some other industrial establishments.

CATAMENIA (Gr. *κατά*, according to, and *μήν*, month), or **Meuses**, a monthly flowing of sanguineous fluid, which occurs in the female economy. The function of menstruation generally commences at the age of puberty, and terminates at the "critical period," or "change of life," including a period of some 30 years, between the ages of 14 and 45. The blood of the catamenial flux is exuded from the vessels of the uterus, and escapes through the vagina; the flow generally returns every 28 days, and continues from 3 to 6 days. The amount discharged varies from 4 to 8 oz. in most cases. The first menstrual flow is generally preceded by languor, pains in the back, headache, chilliness, &c., which usually disappear when the discharge takes place. The after occurrences are often unaccompanied in healthy females by any premonitory or attendant symptoms. During the whole of a woman's menstrual life she is capable of bearing children. After it is closed, she ceases child-bearing.—The influence of climate in advancing or retarding the period of puberty and menstruation has been shown by recent observation to have been formerly much overrated, the average period being much the same all over the world, and exceptional cases about as numerous in one region as in another. Mr. Robertson has shown, from statistical evidence, that menstruation does not occur more early in the negress than in the white female, and Dr. Vaigas affirms that precocious menstruation is more common in the

white than in the colored races. Early marriages in Hindostan and other warm climates, then, do not depend on natural precocity, but on the habits and customs of the country.—The uterus is congested during the menstruation, and so are the ovaries and the Fallopian tubes; the tissues of the vagina are relaxed, and the *os uteri* is softened and swollen; these conditions disappear when the flow ceases, and the parts return to their natural state. During pregnancy and lactation the menses usually cease, and they may also be suppressed from other local causes.—Vicarious menstruation sometimes takes place as a means of obviating the ill effects of suppressed menstruation, by substituting a similar discharge from some other part. It occurs from the gums, the nostrils, the lungs, the stomach, or even from the eyes, and other parts of the body.

CATAMOUNT. See COUGUAR.

CATANIA. I. A province of Sicily, on the E. coast, bounded N. by Messina, E. by the Ionian sea, S. by Syracuse, and W. by Caltanissetta and

years the Albanian language and the Greek rite in divine worship. **II.** A city (anc. *Catana* or *Catina*), capital of the province, situated on the E. coast, on the shore of the gulf of Catania, which is an inlet of the Mediterranean, at the foot of Mt. Etna, 30 m. N. N. W. of Syracuse; pop. in 1872, 84,397. It is the handsomest city in Sicily, with wide and regular streets, and numerous and splendid public buildings. Its vicinity to Etna has introduced the use of lava for various purposes. The streets are paved with it, the finest buildings are made of it, and it is formed also into ornamental chimneypieces, tables, and toys. It has many remains of the ancient Roman city, among which are an amphitheatre, a theatre, and ruins of baths and temples. Its principal public edifices are the cathedral, rebuilt since the earthquake of 1693, the senate house, the university, and a vast Benedictine convent. Since 1867 it has been the seat of an archbishop, formerly of a bishop. It is one of the three principal ports of Sicily, and is the

Square of the Elephant.

Palermo; area, 1,970 sq. m.; pop. in 1872, 479,850. It comprises the four districts of Catania, Acireale, Caltagirone, and Nicosia. With the exception of the Piana di Catania (plain of Catania), the province is mountainous, and includes in its limits Mt. Etna. The chief rivers are the Giaretta and its affluents. The Piana is very fertile, but only imperfectly cultivated. Near Militello and Scordia there are, however, flourishing plantations of olives and oranges. The slopes of Mt. Etna are covered with rich pastures. The chief articles of export are sulphur, grain (chiefly wheat), wine, oranges, lemons, nuts, oil, kid skins, linseed, sumach, soda, lava, and snow from Etna, which is sent to the ports of Sicily, to southern Italy, and Malta. Manufactures of silk and cotton are leading industries. A colony of Albanians in this province has preserved for more than 400

leading mart for silk; besides the silks retained for the local manufactories, considerable quantities are exported. Cotton manufactures, which were formerly limited to coarse cloths for home consumption, have recently received a great development. Cotton is also exported to France and England. There are also manufactures of linen, and carvings of amber, lava, marble, and wood.—The city is supposed to have been founded in the latter part of the 8th century B. C. by Greek colonists from the neighboring town of Naxos. It suffered

severely during the Syracusan and Roman wars, and in the first Punic war sided with the Carthaginians, but was among the first of the Sicilian cities to submit to the Romans after its close. It has been several times destroyed by earthquakes and eruptions of Etna; as in 121 B. C., A. D. 1169, 1669, and 1693; but it has each time been rebuilt with greater beauty than before. In 1848 and 1849 there were violent popular outbreaks; and on April 6, 1849, the Neapolitans expelled the Sicilians from the city.

CATANZARO. I. Or *Calabria Ulteriore II.*, a province of S. Italy, in the former kingdom of Naples, bounded N. by Cosenza, E. by the Ionian sea, S. by Reggio, and W. by the Tyrrhenian sea; area, 2,307 sq. m.; pop. in 1872, 412,226. It comprises the four districts of Nicastro, Cotrone, Catanzaro, and Monteleone. One half of the province is level, the other

half partly hilly and partly mountainous. Only a small portion is watered by small rivers. The chief products are vegetables, chestnuts, acorns, milk, cheese, butter, silk, wool, hemp, lumber, oil, and wine. It has several coal mines and marble quarries. **II.** The capital of the province, situated on a mountain near the gulf of Squillace, 30 m. S. S. E. of Cosenza; pop. in 1872, 24,901. It is the seat of a bishop, and has a cathedral, several churches and convents, a castle, a royal academy of sciences, and numerous schools and charitable institutions. Considerable trade is carried on in cattle, corn, and wine, and there are manufactures of silk velvet, embroidery, and carpets. It suffered severely from the earthquake of 1783, which overthrew some of the principal buildings.

CATAPLASM (Gr. *καταπλάσσειν*, to spread over, to plaster), a poultice or soft substance applied externally to some part of the body, either to repress inflammation and allay pain, or to promote inflammation or its consequences, and lessen the pain attending it. For the former purpose it is applied cold, and often contains a preparation of lead to increase its astringent and refrigerating power; for the latter it is used at different degrees of temperature. When intended to hasten the progress of inflammation and lead to suppuration, poultices should be of as high a temperature as the part will bear, but of a lower temperature when used as mere emollients. Cotton wool, steeped in water, and bound to the part with a light bandage, is a very simple and efficient application, in most cases where a cold poultice is required to allay pain and repress inflammation. Warm poultices may be made of bread, slippery elm bark, or flaxseed meal.

CATAPULT (Gr. *κατά*, against, and *πάλλειν*, to hurl), an ancient military engine for throwing stones, darts, and other missiles, invented in Syracuse in the reign of Dionysius the Elder. It acted upon the principle of the bow, and consisted of wood framework, a part of which was elastic, and furnished with tense cords of

Catapult.

hair or gut. Catapults were of various sizes, being designed either for field service or bombardments. The largest of them projected beams 6 ft. long and weighing 60 lbs. to the

distance of 400 paces, and Josephus gives instances of their throwing great stones to the distance of a quarter of a mile. The Romans employed 300 of them at the siege of Jerusalem. From the time of Julius Cæsar it is not distinguished by Latin authors from the *ballista*, which was originally used only for throwing masses of stone.

CATARACT, a disease of the eye in which there is an opacity of the crystalline lens or of its capsular investment. It is most common in old persons, in whom it seems to be the natural consequence of age; but it also occurs in infants, and is even congenital; it appears to be more frequent in cold and damp climates than in warmer regions, and it is certainly hereditary in many instances. Among the exciting causes, especially of the capsular form, are wounds and inflammations of the internal eye; but the ordinary cause is the diminished nutrition of the organ in common with others in advancing age. True cataract may be either lenticular, capsular, or capsulo-lenticular, according as the seat of the opacity is in the lens itself, in its capsule, or in both at the same time. Certain cases of opacity external to the crystalline apparatus have been called false cataracts, and may be caused by the effusion of lymph, blood, or pus, or by false membranes; secondary cataracts are those which follow the surgical operations for the extraction or depression of the lens. The lenticular cataract may vary in hardness from stony to gelatinous; its opacity is rarely uniform, being generally thickest in the centre and thinnest on the edges; in some cases the opacity begins at the circumference in rays which slowly converge to the centre; the color varies from pearly white to amber yellow. The capsular cataract, which Velpeau considers more common than the lenticular, offers a great variety of colors and streaks, and may occupy either the anterior or posterior surface, or both. In the last form of cataract both the lens and its capsules are involved, with the varieties common to both. The physical sign of cataract is a more or less troubled appearance behind the pupil, of a yellowish color, deepest in the centre, and becoming more distinct as the disease progresses; the rational sign is a gradual diminution of vision, accompanied by the sensation as if a cloud, specks, spiders' webs, or snowflakes were passing before the eyes; objects are seen best in certain positions of the head, as when turned on one side, and during the evening or in the shade when the dilated iris permits more light to enter the pupil; on looking at a candle the flame appears surrounded by a thick bright haze. The progress of the disease is very slow, generally unaccompanied by fever, pain, or any disturbance of the general health. It is very rare for a person to be unable to distinguish day from night. M. Sanson has proposed an excellent catoptric test for the detection of cataract by the reflection of light. When a lighted candle is held before the eye of a

healthy person, three images of it may be seen: the first erect, moving upward when the candle is moved upward, produced by reflection from the cornea; the second also erect, produced by reflection from the anterior surface of the crystalline capsule, and moving upward with the candle; the third very small and inverted, reflected from the posterior surface of the capsule, moving downward when the light is carried upward. In cataract, the inverted image is from the beginning indistinct, and soon disappears entirely; the deep, erect one is also soon rendered invisible. By dilating the pupil with belladonna, this experiment is rendered easy and striking. Cataract is for the most part remediable only by a surgical operation; certain forms, caused by inflammation of the capsule, may disappear with the exciting cause without an operation; and cases are on record of the spontaneous cure of lenticular cataract by the rupture of the capsule and the escape of the lens into the anterior chamber of the eye, where it is gradually dissolved.—From the earliest antiquity surgeons have attempted to destroy cataract by means of needles and knives of various forms. Whenever the disease is confined to the lens and its capsule, and the eye in other respects is healthy, and the patient not too young or too old, an operation may be attempted with a prospect of success; in infants, and in persons under 20 years of age, both eyes may be operated on at once; after the age of 80, the chance of a successful issue is generally small. Before submitting persons to this operation, it is well to prepare them a day before by a mild diet and a gentle laxative, and to allay any inflammatory tendency of the organ; and then to smear belladonna ointment around the orbit, or to put a few drops of its fluid extract into the eye, for the purpose of dilating the pupil to its utmost extent.—All operations for cataract reduce themselves to three, which have for their object either to displace the lens, to break it up, or to remove it from the eye. 1. Operation for depression of the lens, or couching. The description of this may be found even as far back as Celsus; it has undergone many modifications in modern times. The instrument employed is a fine needle, either slightly curved at the end or straight with the point spear-shaped; Scarpa's needle is slightly curved at the end. When the needle is passed through the sclerotic, as ordinarily, the operation is called *scleroticomy*; when it is passed through the cornea, *keratonyxis*. Different needles are preferred by different operators; but, as in the case of the stethoscope, that instrument is the best to which the surgeon is accustomed. In *scleroticomy* the needle, held like a pen, is passed through the sclerotic perpendicularly to its surface, a line or two from the cornea and a little below its transverse diameter; the concavity of the instrument is turned down, in order to separate rather than to divide the fibres of the membrane; when the

needle is fairly in, its concavity is turned backward, so that it may pass under and before the lens without touching the iris or the capsule; when it has reached as far as the pupil, the capsule is lacerated by delicate circular movements of the point; then the needle is applied directly to the lens, which is pushed outward and backward to the bottom of the globe, out of the line of the axis of vision; it is held there a short time, that the cells of the vitreous humor, into which it is pushed, may resume their position around it, and thus prevent its reascension in the line of the pupil. Some surgeons prefer the operation by reclination, which consists in turning the lens backward from an upright to a horizontal position; and some always recline the lens before they depress it. In *keratonyxis*, the needle is passed through the cornea, about an eighth of an inch from the sclerotic, on its lower and exterior portion, and is directed through the dilated pupil to the lens, whose capsule it is made to lacerate; and, if possible, the lens is depressed, reclined, or broken up. This method is objectionable on account of the danger of wounding the iris, and of the difficulty of reaching the lens, and is applicable only to exceptional cases. After the operation, the eye should be lightly covered, and the patient should remain in bed in a darkened room, with the head raised, and be kept on a low diet for a few days; after four or five days in ordinary cases, a little light may be gradually let into the room, and at the end of three weeks the eye may be generally left uncovered. The accidents most to be feared are inflammation of the iris, choroid coat, and retina, which should be treated by antiphlogistic measures. 2. The operation for breaking up the lens, without depressing it, is very easily performed, and excites very little inflammation; but it requires frequent repetition, is slow in its progress, and is adapted only to soft and especially to congenital cataracts. The needle is inserted just as in the method for depression, the capsule is divided, and the lens is freely broken up without removing it from its place; the cataract is thus brought into contact with the aqueous humor, and is gradually dissolved by it. 3. In the operation for extraction, the cornea is incised through rather more than half its circumference, the capsule is lacerated, and the lens is extracted from the eye entire; it is performed with a triangular knife, with sharp point, straight and blunt back, the edge slanting obliquely, and the blade growing wider and thicker as it approaches the handle; this kind of knife cuts by the simple motion of pushing, and fills up the incision as it makes it, thereby preventing the escape of the aqueous humor. The cornea may be cut on its inferior or superior half, or obliquely on its external and lower portion, each of which has its special advocates. When the lower half is cut, the knife, with its edge downward and forward, is passed into the external side of the cornea, perpendicular to its axis, a little above its transverse diameter, and about a line from the scle-

rotic; passing in front of the iris, the point is made to cut its way out on the inner opposite surface; the cutting of this flap constitutes the first period of the operation, after which the lids are permitted to be closed for a few seconds. Taking care in the subsequent steps of the operation not to make pressure upon the globe, the surgeon raises the flap, and, by means of a proper needle, lacerates extensively the capsule; if at this time the lens does not of itself come forward into the anterior chamber, gentle and properly directed pressure will cause it to come out; to complete the operation, it is sometimes necessary to remove also the pieces of the divided capsule. When the lower half of the cornea is opaque or in a condition unfavorable to cicatrization, or very small, Wenzel, Richter, and Jäger recommend the section of the upper half; the steps of the operation are about the same, though perhaps more difficult to execute; it offers the advantages of presenting less liability of the iris being wounded, of the vitreous humor escaping, and of the lips of the section being separated by the edges of the lids. By the oblique incision, which is the favorite mode in France, the lids could not possibly interfere with the apposition of the edges of the wound. More care is required after extraction than after depression, to avoid inflammation; after it is certain that the patient can distinguish objects, the eye is lightly covered and the person confined to bed in a dark room, with the head but slightly elevated.—Of these operations, extraction removes with certainty the obstructing lens, is very little painful, does not wound the ciliary vessels or nerves, the choroid, or the retina; but it may cause deformity of the pupil or the escape of the vitreous humor; the edges of the wound may not readily heal, or may ulcerate, with hernia of the iris or opacity of the cornea. Depression leaves a permanent cause of irritation in the eye, and the lens is liable to reascend; the needle perforates the choroid and retina, and may cause inflammation of the internal eye; but there is no danger of the escape of the vitreous humor, nor of spots or ulcers of the cornea, nor of hernia of the iris, nor of immediate evacuation of the globe. Depression is best in children and intractable persons, where the eyes are small and deep-seated, the cornea flat, or the conjunctiva irritated. When the cataract is soft and the pupil small or adherent, extraction is best in old persons, in adults with a large anterior chamber and the eyes sound, and when the cataract is hard or membranous. Convex spectacles are necessary, under proper restrictions, to supply the place of the extracted crystalline lens.

CATARRH, a non-inflammatory disease, characterized by an increased secretion of mucus from the glands of the mucous membranes. The name is popularly confined to disease of the membrane of the air passages, but it should be extended to that of the intestinal, urinary, and even genital mucous membranes. Children and

adults of the lymphatic temperament are most subject to catarrh; and it occurs most frequently in cold and damp seasons, accompanied by sudden changes of temperature, and in individuals weakened by insufficient food, foul air, and mental anxiety; it also occurs epidemically. Catarrh of the air passages is rarely accompanied by any constitutional disturbance; the principal symptoms are sneezing, increased secretion of tears and mucus, and a snuffling nasal respiration. In many cases of catarrh of the bladder, the urine is loaded with mucus, and the state of its membrane highly irritable, without being positively inflamed. Catarrhal diseases often occur epidemically, under the name of catarrhal fevers, in which there seems to be a morbid disposition in all the mucous membranes to secrete an excess of mucus. Besides the conditions already mentioned, the genital mucous membrane may be affected, constituting some form of leucorrhœa and blennorrhœa; the conjunctiva may also be attacked, giving rise to catarrhal ophthalmia; some of these conditions, especially the last two, may become contagious, without the usual specific origin.—These catarrhal diseases are not generally dangerous; but they are apt to become chronic and exceedingly difficult to remedy, when the lungs, stomach, intestines, and genito-urinary organs are affected, and especially when occurring, as they often do, in old and debilitated persons. The treatment of the mild forms is entirely expectant; in the chronic stages, the principal dependence is on tonics and stimulants, especially quinine, and on local applications of a stimulating and alterative character whenever the seat of the disease is directly accessible. They form some of the most obstinate cases which the physician has to manage, both from the difficulty of direct medication, and from the age and weakness of the majority of persons who suffer from them.

CATASAUQUA, a borough of Lehigh co., Penn., on the left bank of the Lehigh river, 3 m. above Allentown; pop. in 1870, 2,853. It contains 7 churches, a bank, 4 hotels, a semi-monthly periodical, 2 machine shops, 2 rolling mills, gas works, and 5 blast furnaces, one of which produces 250 tons of iron a week. The Lehigh Valley and the Lehigh and Susquehanna railroads are joined here by the Catasauqua and Fogelsville railroad.

CATAWBA, a W. central county of North Carolina; area, 250 sq. m.; pop. in 1870, 10,984, of whom 1,703 were colored. It derives its name from the Great Catawba river, which forms its N. and E. boundary, and is drained by the South Catawba. The surface is diversified, and the soil fertile: Iron ore is abundant. It is crossed by the Western North Carolina railroad. The chief productions in 1870 were 34,746 bushels of wheat, 142,876 of Indian corn, 41,553 of oats, and 22 bales of cotton. There were 1,252 horses, 1,458 milch cows, 2,135 other cattle, 4,644 sheep, and 6,768 swine. Capital, Newton.

CATAWBA, or *Great Catawba*, a river of North and South Carolina. It rises in the Blue Ridge, in McDowell co., N. C., flows nearly E. through the gold region of North Carolina, makes a bend to the south at the W. border of Iredell co., and enters South Carolina near the mouth of the Little Catawba, or Catawba creek, in York co. After reaching Rocky Mount, and being joined by Fishing creek, it takes the name of the Wateree, and ultimately unites with the Congaree to form the Santee. The length of the Catawba is about 250 m.; that of the Wateree, 100 m.

CATAWBAS, a tribe of Indians in North and South Carolina, on the Catawba river, now reduced to a mere handful. At the time of the settlement of those states they were a powerful tribe with 1,500 warriors. Some affirm that they came from Canada, but their language has no affinity with that of any northern nation, is closely connected with that of the Waccos and the Carolina tribe, and has affinities with the Muskogee and even the Choctaw. They are said to have been called also Usherees. They occupied Nauvasa and five other towns on the Catawba river, in a most delightful country. They were a warlike people, and were early engaged in hostilities with the Cherokees, and subsequently with the Shawnees and Iroquois. They were always friendly to the Carolina settlers, and served with them against the Tuscaroras and Cherokees, and in the revolution. Having improvidently leased their lands, they migrated to the Cherokees, but returned and settled on a reservation given to them. War and disease gradually reduced their numbers. From 7,500 at the time of the settlement, they had decreased to 2,000 in 1728, and 450 in 1822. Peter Harris, the last full-blooded Catawba, was a revolutionary soldier. There are now perhaps 200 half-breeds bearing the name on the reservation. Pontiac, who attempted to destroy the English power in the northwest, is said by some to have been by birth a Catawba. This tribe was one of those which flattened the heads of infants.

CATAWBA WINE. See AMERICAN WINES.

CATBIRD (*mimus Carolinensis*, Gray), a bird of the thrush family, peculiar to North America. It receives this name from its well known note, which resembles the mew of a half-grown cat; this is not, however, its only note; its morning and evening song of wild warbling melody is worthy of the musical family to which it belongs. The catbird is found from Maine to Florida, making its appearance from the south toward the last of February, reaching the middle states about the second week in April, and New England about May 1; it is one of the few species which follow the course of agriculture, being rarely found far from the habitations of the farmer. Its general form is more slender and graceful than that of the American robin. Its plumage is soft and blended, the tail long and rounded at the tip; the bill is black, slightly arched; the general color

of the upper plumage is blackish gray or slate color, the head, tail, and inner webs of the quills being of a brownish black; the cheeks and general under plumage are of a deep bluish gray, paler on the abdomen, the under tail coverts being brownish red; the outer tail feather is transversely striped with white on its inner web; the plumage of the female is of a somewhat paler tint. Length 9 inches, extent of wings 12 inches, length of tarsus $1\frac{1}{2}$ inch. The nest is large, generally made in bramble thickets, and constructed of twigs and briars mixed with leaves, weeds, and grass, lined with dark fibrous roots arranged in a circular manner. The eggs are from four to six in number, of a greenish blue color, without spots. Its food consists of insects and fruits and berries of all kinds, especially of the sweetgum, poke, and sumach. It migrates during the night. It is very lively in its manners, and will follow with impudence for a considerable distance any intruder on its locality, mewing as it sits on a twig, jerking its tail from side to side. It is very irritable, and hates especially cats and snakes. Its attachment to its young is very remarkable,

Catbird (*Mimus Carolinensis*).

and it will often feed and raise the young of other species. Besides its own song, it possesses considerable imitative power, mocking the notes of other birds in an imperfect manner; according to Latham, it will, when in a domesticated state, imitate strains of instrumental music. Though this bird is generally persecuted, it deserves the kindest treatment for its services to the agriculturist in devouring wasps, grubs, worms, and insects, which would have destroyed tenfold more growing fruit than it ventures to claim at the season of maturity. Its flesh is good, but is rarely used for food.

CATEAU, Le, or **Cateau Cambrésis**, a town of France, in the department of Le Nord, on the river Selle, 17 m. S. of Valenciennes; pop. in 1866, 9,974. It is well built, has salt works, manufactories of merinoes, shawls, calicoes, soap, and tobacco, and is noted for producing a superior quality of linen thread. Two treaties were signed here on April 2, 1559, between England and the Netherlands on the one side, and France and Scotland on the other, and on the following day between France and Spain.

CATECHISM (Gr. *κατηχησμός*, instruction), in a general and modern sense, an elementary text book of any science or art. More commonly, however, it means a text book for the instruction of the catechumens and children of a parish or congregation in the doctrines of the church, or the moral precepts of Christianity. The original form of this instruction was oral, by question and answer. The practice was to gather those who needed instruction into some suitable place, and there persons qualified either held disputations or delivered dogmatic lectures, and then questioned the hearers upon what had been said. It is probable that the early catechists followed no set forms, but endeavored, by catechising their hearers, to awaken a train of thought, and then followed it whithersoever it might lead. But when the doctrinal theology of the church became more strictly defined, catechetical instruction became more dogmatic. These compends have of course varied with the variations of theological opinion in different ages and communions. A formula of doctrine, the *Catechismus Romanus*, was drawn up by order of the council of Trent, and published at Rome in 1566, under the sanction of Pope Pius V., and was subsequently approved by special bulls and adopted by vote of provincial synods in various Catholic countries. It was ordered that it should be faithfully translated into the vernacular languages, and expounded to the people by all pastors. But it was designed as a directory for the use of the clergy rather than as a system of popular instruction. It was not originally in the form of question and answer, though some later editions are in that shape. In common use in various parts of the Catholic world were the catechisms drawn up by Canisius (1554 and 1566), by Bellarmin (1603), and by Bossuet (1687). A catechism designated as *Schema de Parvo*, essentially that of Bellarmin, was decreed by the œcumenical council at Rome in 1870, its object being to provide a common catechism for the whole church. Strictly speaking, the Greek church has no authorized catechism; but that of Mogilas, metropolitan of Kiev (1642), was in 1672 recognized as a standard by a synod at Jerusalem. The principal Protestant catechisms are those of Luther (1529) and Calvin (1536); the Heidelberg catechism (1562), on the basis of which the Zürich catechism was drawn up (1639) for the Reformed church of Germany; that of the Socinians, published at Raków (1574 and 1608); that of the English church, the work probably of Cranmer (1549), with the exception of that part which relates to the sacraments, which was added by Bishop Overall in the first year of James I., after the conference of Hampton court; and that of the Westminster assembly, longer and shorter (1643), which serves as a basis for the Calvinistic and Presbyterian churches both of Great Britain and the United States. There are many mediæval writings and documents bearing the name of catechisms, which if collected together would

form a work similar to the collections already made of old liturgies and hymns. The private or individual catechisms of German theologians are numerous, and many of them voluminous, thus departing from the primitive idea of the Christian catechism as an instrument for popular and elemental instruction.

CATECHU, an extract of the inner wood of the *acacia catechu*, a small tree which grows abundantly in the East Indies. The drug had long been in use before its origin was discovered. It is prepared by cutting off the exterior wood, and boiling the dark-colored chips of the interior of the trunk in water. The solution is then evaporated to the consistence of sirup, when it is dried in the sun in the form of flat cakes, or moulded by pouring it into earthen vessels. There are many varieties, some of which probably never reach this country. That common in our markets is the preparation above described, and is imported from Calcutta.

Acacia catechu.

The pale catechu of the British pharmacopœia, or gambir, is probably the substance formerly called *terra japonica*, and is the product of another tree, the *uncaria gambir*, of the family *rubiaceæ*. Catechu contains from 33 to 55 per cent. of that variety of tannic acid which precipitates the persalts of iron of a greenish black. Catechuic acid, in some respects resembling gallic acid, is found both in the dark and pale catechu. Catechu is used in dyeing and tanning under the name of cutch. It is used in medicine, in substance and tincture, as an astringent. It is said to be slightly tonic.

CATEL, Franz, a German artist, born in Berlin, Feb. 22, 1778, died in Rome, Dec. 19, 1856. His early works were designs for illustrated almanacs, and he first acquired reputation by his illustrations of Goethe's *Hermann und Dorothea*. He went to Paris in 1807, where he was led to abandon water colors and begin painting in oil. At this time, however, he designed

a series of beautiful vignettes for Caro's Italian version of the *Æneid*. Going to Rome in 1809, he painted historical, genre, and landscape subjects successively, and greatly modified the style which he had acquired at Paris. In 1834 he painted a "Resurrection of Christ" for the Luisenkirche at Charlottenburg near Berlin, a large work containing many figures. With this exception, his most celebrated paintings are landscapes. Of these, his views of Naples, Vesuvius, Sorrento, Salerno, and in Sicily, to which island he went in 1818, are considered the best. His works found their way over all Europe, and as they commanded high prices he became rich. In 1841 he was made a member and professor of the academy of Berlin. He left his fortune to be invested for the benefit of poor artists.

CATERPILLAR, the common name of the larvæ of lepidopterous insects, including butterflies and moths. Caterpillars vary greatly in form and appearance, as may be judged from the fact that about 600 species are known in

1. Smooth Caterpillar (*Asterias*). 2. Hairy Caterpillar (*S. acrea*). 3. Spanner (*Geometra*).

New England alone, and probably many are yet unknown. The body is composed of 13 segments; the first constitutes the head, containing the jaws and oral appendages; the second, third, and fourth form the thorax of the future insect, and the remaining ones make up the abdomen. The head is rounded, and of a harder consistence than the body; on each side are six very small *ocelli*, or simple eyes, with a very convex cornea and a spherical crystalline lens, two short antennæ, and a mouth, with strong jaws moving transversely; the mandibles are hard, for breaking up the food, while the maxillæ are soft and adapted rather for holding it; in the middle of the lower lip is a conical tube, through which issue the silken threads from which their nests and cocoons are made, and their suspensory fibres; a viscid fluid, enclosed in two long and slender bags, is poured out through the "spinneret" in a fine stream, and hardens into silk on contact with the air. The segments of the body are very nearly equally developed; the second, third, and fourth have each a pair of tapering, jointed legs, covered with a shelly skin and ending with a little claw; these are the rudiments or cases of the future limbs, and are

the true organs of locomotion; some of the other segments are furnished with soft, jointless, fleshy, and contractile legs, called prop legs, which disappear with the larval condition, being only prolongations of the external covering and shed with it, like the nails and claws of the higher animals; the abdominal legs vary in number from four to ten, and are provided around the margin of the sole with rows of minute hooks capable of such direction as is necessary for a secure hold. The body is in some cases smooth, in others hairy, and even spiny; these external appendages, whether for ornament or defence, are shed with the skin before the pupa state. Where the middle portion of the body is unprovided with feet, the caterpillar adopts the arched or looped manner of walking, so familiarly known in the common canker worm; these species are hence called spanners, loopers, surveyors, and geometers; some, when in a state of repose, fix themselves by the hind legs only, and project in a rigid condition from branches, which they then much resemble in direction, form, and color; the power of remaining thus immovable for hours at a time must be due to a muscular force of which we have no idea in vertebrate animals; the species which have eight to ten intermediate feet walk by short steps, in a continuous worm-like manner. Some smooth caterpillars, as those of the sphinx moth (commonly called potato worm), have a spine or thorn upon the top of the last segment of the body, directed backward and curved; though this looks like and has been considered an offensive or defensive weapon, its softness is such that it could inflict no wound. The larvæ of some of the hymenopterous insects, as of the saw flies (*tenthredinidæ*), resemble caterpillars both in form and habits; but these false caterpillars may be distinguished by their greater number of legs (18 to 22), and by the absence of the numerous hooks in their prop legs; the larvæ of other insects, having the same number of segments, are scaly and not soft and membranous. On each side of the body are nine oval apertures, spiracles, or *stigmata*, situated in the second, fifth, and following segments to the twelfth, provided with valves; these communicate directly with the internal respiratory organs, which are in the caterpillar branching tubes; in the perfect insect, the tracheæ are dilated into an immense number of vesicles permeating every part of the body. The intestine is short and straight. The nervous system is a series of ganglia connected by chords, one for each segment, the greater part of it in the perfect insect being concentrated in the head and thorax. Caterpillars vary greatly in size; the mean may be taken at an inch, those much exceeding this being large, while those much below it may be considered small; those which have only eight feet in all are the smallest, and are generally the moths' caterpillars. The size of a caterpillar compared to that of the egg is very great, and the rapidity of its

growth is truly astonishing; there is no large animal at all comparable to it for voracity, for some species will eat in 24 hours more than double their own weight; though less voracious than locusts, they are quite as destructive from their greater fecundity and their wider distribution over the vegetable world. According to Count Dandolo, the common silkworm, during the 30 days in which it attains its full size, increases in length from 1 to 40 lines and in weight from $\frac{1}{100}$ to about 95 grains; during this period, therefore, it has increased 9,500 times in weight, and has eaten 50,000 times its weight of food. The caterpillar of the privet hawk moth on leaving the egg weighs about $\frac{1}{80}$ of a grain, and at the end of 32 days, when it has acquired its maximum size, it has been known to weigh 142 grains, and to measure over 4 inches in length, thus increasing more than 11,800 times its original weight. According to Lyonnet, the larva of one of the carpenter moths (*cosus ligniperda*, Fabr., or genus *xyleutes* of Newman), during the three years in which it is supposed to remain in the caterpillar state, increases 72,000 times its first weight by a great accumulation of fat for its nutriment in the pupa and perfect states. Most caterpillars feed on vegetable substances, the leaves, flowers, roots, buds, seeds, and even the wood of plants; many domestic pests gnaw woollens and furs, leather, and fatty substances; while some are quite exclusive in their diet, others are more indiscriminate feeders. When they are very numerous, scarcely any plant escapes their attacks, and at such times their ravages are deplorable, reducing trees in mid-summer to their winter leafless livery. Plants with acrid juices are the favorite food of some species, and the nettle and other spiny shrubs are the natural habitats of many smooth and tender-skinned varieties. Most feed on the exterior of plants, but some of the most destructive and most delicate live in the interior of branches and stems. The sweetest fruits, as pears, plums, and apples, ripen and fall prematurely, the abodes of caterpillars; plums are especially liable to be thus inhabited; while the peach and apricot are free from all larvæ; it has been observed that a single fruit rarely contains more than a single caterpillar, the second inhabitant, if there be one, being the larva of some other order of insects. Wheat, rye, barley, and other grains are infested by small caterpillars, which gnaw away the whole interior without any external perceptible trace, so that an apparently sound heap may be only a collection of useless skins; a single grain contains just the quantity of provision necessary for the transformation of the insect. Another example of the instinct of the lepidoptera is seen in the fact of their depositing their eggs on the parts of the plant which will furnish an easily accessible supply of food to the caterpillar when it is hatched; their eggs are found glued to fruits, and to flowers that are to produce fruits, between the very petals, so that the young find themselves sur-

rounded by an immediate supply. Caterpillars are remarkable for the eagerness with which some species will feed upon their fellows, in preference to vegetable substances in profusion around them. Different species select different times of day for feeding; some eat at all hours, some in the morning and evening, and others only at night; a knowledge of these habits is of great advantage for the easy destruction of many pests of the vegetable garden. Though generally disgusting objects, the contrast and brilliancy of the colors in some of them are eminently beautiful. Some species herd together in great numbers, constructing their silken habitations in common; others live solitary, exposed to light and air, or protected in rolled leaves or silken sheaths; others burrow in the ground, or conceal themselves in the stems of plants and the pulpy substance of leaves. The caterpillars which live in one nest all come from the eggs of a single insect, and are generally hatched on the same day; from 200 to 700 may thus be found together, and may remain so through the chrysalis condition, or may sep-

Processionary Caterpillars.

arate at different periods of life; some, though living in great numbers on the same tree, are solitary with respect to each other, performing no work in common; the most solitary are the leaf-rollers, which are also the most remarkable for their vivacity. For the mechanism of the various abodes of caterpillars the reader is referred to the works of Réaumur, Latreille, Kirby and Spence, and other practical entomologists. The attitudes assumed by caterpillars when attempts are made to catch them are characteristic of species in many cases; some roll themselves into a ring and remain as if dead, the hairy ones resembling little hedgehogs; others fall instantly to the ground and try to escape by rapid flight; some attempt to defend themselves by various motions of their bodies. The mode of marching adopted by the "processionary caterpillars" is very remarkable; these live in society, and when they quit their nest they go in a regular procession, a single caterpillar first and the others in

single file, or two, three, and four abreast; the line is so perfect in the columns, that the head of one is never beyond that of another in the row; following their leader, stopping when he stops, they make journeys from tree to tree in search of food, returning to their nest in the same order; they form their ranks, march, and halt, with the precision of soldiers; when several nests are in the same wood, the spectacle of these creeping battalions, issuing forth and returning at the same hour, is exceedingly interesting; the processions generally take place toward night. Another species, common in pine forests and living together, walk in procession in single file, often very long, the head of each in contact with the tail of the one in advance; they defile in a straight line, or in a variety of graceful curves; they sometimes go to great distances from the nest, always with the same slow and grave step, following exactly their leader; they return to the nest by the same path, which they find not by the sense of sight but of touch; the path of exit is covered as they go by a silken tapestry, and they return upon the same delicate carpet, however tortuous may have been their way. Caterpillars change their skins several times before attaining their perfect state, spinning for themselves a sort of cocoon of silk, interwoven with hairs of their own, with bits of leaves, and even with particles of earth, suspending themselves by silken threads, or burying themselves in the ground. (See BUTTERFLY, vol. iii., p. 495.) Those lepidoptera which pass the winter in the egg live in the caterpillar form during a part of the summer; the eggs are protected against cold by the shell and by the sheltered or subterranean situations in which they are placed; others pass the winter as caterpillars, concealing themselves under stones and the bark of trees, or descending deep into the ground where the cold cannot reach them; the social varieties retire to their warm and water-proof nests; these come forth in the spring quite well grown, but most pass the winter in the form of chrysalis, in protected or in open situations; a few pass this season as perfect insects. The natural enemies of caterpillars are numerous; almost all insectivorous birds and poultry devour them eagerly; other insects not unfrequently feed upon them; and little maggots developed in their bodies from the eggs of the *ichneumonidæ* cause thousands to perish prematurely. In the northern states there are about 1,000 different kinds of butterflies and moths; as each female lays from 200 to 500 eggs, these species, from a single female each, would on an average produce in a year 300,000 caterpillars; if one half of these were females, the second generation would be 45 millions, and the third 6,750 millions; with such fecundity it may well be imagined that the destructive powers of caterpillars must be very great. The work of Dr. Harris on "The Insects Injurious to Vegetation," under the head of "Lepidoptera," gives an extended and valuable account of the ravages of caterpillars

in America, particularly in New England. Alluding to laws in France and Belgium which require the people to "uncaterpillar" their gardens and orchards, under the penalty of a fine, he thinks similar regulations might be enacted here with advantage, or at least that the towns might offer a respectable bounty for caterpillars by the quart, thus affording remunerative and highly useful employment to children and otherwise idle persons.—For notices of many destructive caterpillars see HAWK MOTH, MOTH, and articles under the popular names of the most noted species.

CATERPILLAR FUNGUS, or Fungoid Parasites, a name given to many species of fungi which attack various insects, especially the larvæ of beetles and moths, filling out their bodies, and sending out shoots into the air, so that the animal looks as if transformed into a vegetable. They have been generally described in works on botany, the plant portion having attracted the most attention. Mr. G. R. Gray has specially described the insect portion, taking them up in the usual order of entomological systems. These parasitical plants or fungi infest insects of all orders, and in the larva, pupa, and perfect states; some, however, are from their habitats peculiarly exposed to these growths. The beetles, many of which in all their stages live in the ground, amid decaying vegetable and animal matters, are very liable to these attacks; the growth, no doubt, begins internally, as specimens have been found in which the fungus was just bursting forth from some part of the body; the most usual place for the fungus to appear is from the pectoral surface of the thoracic segments; the larvæ usually lie upon that side, and are generally found dead, and either decayed or dried up; one parasite is ordinarily all that is found on one larva, but two, three, or more are occasionally found. The diurnal lepidoptera have not been seen infested with fungi or moulds, while the nocturnal ones are very much affected; the muscardine, which destroys great numbers of the silkworm, belongs to this class of vegetable parasites. Among orthoptera, the mole cricket; among hymenoptera, ants, bees, wasps, and hornets; among hemiptera, the *cicada*; and among diptera, the flies, are often seen more or less covered with a delicate mould or fungus, which bursts out between the segments of the body, and sometimes grows with great rapidity. From numerous observations, it is certain that life is not extinct when the insect becomes the basis of the parasite. Most of the insects thus affected are vegetable feeders, and it is generally admitted that the spores or seeds of the fungus are swallowed with the food, and that the seeds do not become attached to the exterior of the body and thence penetrate to the interior; some believe that the seeds may also gain admission by the tracheæ or breathing apparatus. These spores are so exceedingly minute as to appear like smoke in the air, and Fries has estimated

above 10,000,000 in a single plant; their minuteness, however, is not so wonderful as that each contains the elements necessary for germination. However admitted, the seeds begin to germinate, gradually grow if the circumstances are suitable, and fill the animal completely with the thallus; the insect retains its external form, though internally its fluids are dried up by the growth of the fungus; the plant then forces its way through the skin at various places, through the articulations, and even through the hard surface of the head. It may be that the vegetable growth does not always depend on its being nourished by the fluids of the insect; but that the latter, enfeebled by the heavy rains that fall periodically in the intertropical regions, where these growths abound, receives the seed, which grows by the influence of external moisture, and by its thallus interferes mechanically with the functions of the insect, and finally destroys it. A vigorous larva might even devour the parasitic seed, which, not finding a suitable nidus, might be voided in the usual way. These growths vary in length from a mere protuberance to 10 inches, and in diameter from a fine hair to one fourth of an inch. Most of them belong to the old genus *sphaeria*, which has been subdivided into many genera, which, with many other apparently very different forms, may be more or less immature growths of totally dissimilar described genera. The fungi infesting insects are not peculiar to them, as they infest all organic and decaying matter.—See "Proceedings of Boston Society of Natural History," vol. xi., p. 120, Feb. 6, 1867.

CATESBY, Mark, an English artist and naturalist, born about 1680, died in London, Dec. 24, 1749. After studying the natural sciences in London, he went to Virginia, and remained in America seven years, returning to England in 1719 with a rich collection of plants. Encouraged by Sir Hans Sloane and other friends of science to revisit America, he arrived in South Carolina in 1722, explored the lower parts of that state, and afterward lived for some time among the Indians about Fort Moore, 300 m. up Savannah river; after which he continued his researches through Georgia and Florida. After spending three years upon the continent, he visited the Bahama islands, constantly occupied in delineating and collecting botanical and zoölogical objects. He returned to England in 1726, and published in numbers his great work on the "Natural History of Carolina, Florida, and the Bahama Islands" (2 vols. fol., 1731-'48; new eds., 1754 and 1771). The figures were etched by himself from his own paintings, and the colored copies were executed under his own inspection. He was a member of the royal society, and wrote *Hortus Europæ Americanus* (1767), and a paper on "Birds of Passage" in the "Philosophical Transactions."

CATFISH, one of the *malacopterygii* or soft-rayed fishes, of the family *siluridæ*, and of the genus *pimelodus* of Cuvier; characterized by a

smooth palate, the palatic bones often having teeth, but with no band of teeth parallel to those of the upper jaw; the head ornamented with eight fleshy barbules; skin naked. Dr. Storer describes 16 species as occurring in the fresh-water streams and lakes of North America, and there are about 50 in various parts of the world.—The common catfish, or horned pout (*P. atrarius*, De Kay), is one of the most common fishes of our rivers, and is by many preferred as an article of food to all other fluviatile species except the pickerel; specimens are occasionally met with weighing three quarters of a pound. Length 7 to 9 in.; color dusky, almost black on the head and back, lighter on the sides, and white beneath, in front of the ventral fins, which are behind the pectorals. Upper jaw the longer; tail nearly even and rounded; head smooth and flattened; skin naked and covered with a mucous secretion. It has two fleshy barbules on the top of the head between the snout and eye; at the angle of the upper jaw are two thick fleshy barbules, reaching to the middle of the pectoral fins, and there are four others under the lower

Horned Pout (*Pimelodus atrarius*).

jaw. The mouth is capacious. There are two blunt spines midway between the eye and the opening of the gills; the first ray of the first dorsal fin is strongly spinous; the second dorsal is fatty; the pectoral fins have also a serrated spine; these spines become fixed and immovable at the will of the animal, and serve as formidable defensive weapons. Varieties sometimes occur in this genus without ventral fins, and such have been described as a new genus, *pimapterus*. This species is the most common one in the New England and middle states, and is found in the great lakes and along the Atlantic states from Maine to Florida. It prefers muddy bottoms, as do all the species of the genus.—The great lake catfish (*pimelodus nigricans*, Lesueur) is from 2 to 4 ft. long, weighing from 6 to 30 lbs.; it is found in Lakes Erie and Ontario. This is of a deep olive brown color, and has the tail forked. Other species are the Huron catfish (*P. canosus*, Rich.), 10 in. long, found in Lake Huron; northern catfish (*P. borealis*, Rich.), 30 in. long, found in the northern regions; the white

catfish (*P. albidus*, Lesueur), of a whitish ash color, 12 to 15 in. long, from Delaware; the mudfish (*P. punctulatus*, Cuv.), 2 to 3 ft. long, of a brown color spotted with black, from Louisiana. Among the large species found in the Ohio river and its tributaries are the *P. aeneus* (Les.), 2 to 3 ft. long; *P. furcatus* (Les.), 1 to 4 ft. long; *P. cupreus* (Raf.), 1 to 4 ft. long; *P. limosus*, *P. cærulescens*, and *P. xanthocephalus*.—The catfish are sluggish in their movements, securing their prey rather by stratagem than by swiftness. The female moves about with her young, like a hen with her brood. Though their flesh is generally esteemed in the country and on the western rivers, it is very insipid to persons accustomed to salt-water fishes.—Catfish is a name applied to other species of different genera, and among others to the ferocious *anarrhicas lupus* (Linn.), more properly called wolf-fish.

CATGUT, string made of the dried and twisted intestines of animals. Such strings are usually made from the intestines of sheep, but sometimes from those of the horse, ass, or mule. They are used on violins, harps, and other musical instruments, for the cords of bows, clocks, and whips, and for belting. They are prepared by first being freed from all feculent and fatty substances, then soaked and divested of the outside or peritoneal membrane by scraping, again soaked and the inner or mucous membrane taken away, and still further cleaned by the use of lye. They are next exposed to fumes of burning sulphur to purify them, and are slit and twisted into different sizes. They are then dyed, and afterward, as they are stretched upon frames, dried and hardened by exposure to a temperature of 180° to 200°. Lastly, they are cut off and coiled up for sale. Otto, in his "Treatise on the Violin," says that the best strings are those from Milan, sold by the name of Roman strings; and as these are imitated by inferior cords made in Bohemia and the Tyrol, he gives the following as the marks of the best article: "The Milanese strings are as clear and transparent as glass. The third string should be equally clean as the first. They must by no means feel smooth to the touch, for they are not ground or polished off by any process, as all other manufactured strings are. If a good string be held by one end in the finger and opened out, it will recoil to its former position like a watch spring. Every string when stretched on the instrument should look like a thin strip of glass on the finger-board; those which are of a dull and opaque appearance are useless. Their elasticity is after all the best criterion, as no other strings which I have tried have that strength and elasticity for which the Milanese are so much esteemed."

CATHARINE I., empress of Russia, born according to some in Livonia, according to others in Sweden, about 1685, died in St. Petersburg, May 17, 1727. She was formerly believed to have been the daughter of a Swedish quartermaster, John Rabe, but is now more generally

represented as the daughter of a Lithuanian peasant, Skavronski; her own original name was Martha. Left an orphan in a village of Livonia, she was taken care of by the sexton of the place, and subsequently by Glück, the Protestant minister at Marienburg, who educated her with his children. In 1701 she married a Swedish dragoon of the garrison of Marienburg; but the campaign of 1702, in which he had to serve, and the capture of Marienburg (Aug. 23) by the Russians, under Sheremetieff, separated them for ever. Martha, together with the family of her protector, Glück, was made captive by the Russian general, who treated the old clergyman kindly, but retained the females. At the distribution of the spoils, she was allotted to Gen. Bauer, whose mistress she was until she was ceded by him to Prince Menshikoff. It was in the house of the latter that Peter the Great saw her, was captivated by her beauty, and made her his mistress (1703). She adopted the Greek creed, and with it the name of Catharine Alexievna. In 1706 she bore a daughter, Catharine; in 1708 (after having been privately married to Peter) Anna, afterward duchess of Holstein-Gottorp, and mother of Peter III.; in 1709 Elizabeth, afterward empress of Russia. She maintained her influence over Peter by her vivacity, activity, and good temper. She shared the troubles and fatigues of his campaigns, and frequently calmed the wild outbreaks of his savage temper. When in 1711 his great rival, Charles XII., who after the defeat of Poltava (1709) had found refuge and protection in Turkey, had succeeded in arming that empire against the Russians, and Peter, after an imprudent march, found himself reduced to the extremity of starving on the banks of the Pruth, or surrendering his army, Catharine, with the assistance of Ostermann and Shafiroff, saved him by bribing the Turkish grand vizier with her jewels. Peter proved his gratitude by acknowledging her as his wife in 1712, and declaring her empress in 1718. As such she was crowned in Moscow in 1724. The determination of Peter to make her his successor was shaken by his suspicions of her conjugal fidelity, and still more in 1724 by his conviction of her infidelity, in consequence of which the chamberlain Moens was beheaded (ostensibly for mismanagement in office), his sister ignominiously flogged, and his two sons sent to the army in Persia. It has been asserted that Catharine, having been shown by Peter the head of Moens, still hanging on the scaffold, said calmly, "What a pity that the people of the court are so corrupt." She succeeded, however, in strengthening her position by reinstating Menshikoff in the favor of Peter, which he had previously lost by his devotion to her. But still so doubtful was her situation, that at the death of Peter (Feb. 8, 1725), which was kept secret until her succession was secured, she could not avoid the suspicion of having poisoned her husband. The archbishop of Pskov, Theophanes, declared

under oath to the people and the army that Peter on his deathbed had designated her as the worthiest of succession, and the guards, the synod, and the high nobility gave their consent, and the people their oath of fidelity to the first "empress" and autocrat of all the Russias. The policy of Peter was continued under the leading influence of Menshikoff; the Russian academy of sciences was founded, silver mines were opened in Siberia, and the naval exploring expedition under Behring was fitted out. But soon the caprices of the empress, who was guided by favorites, and intemperate in drinking, were felt in the management of affairs, and blunders committed, while her ruined health prepared a sudden end. Her successor was Peter II., the grandson of Peter and son of the unfortunate Alexis.

CATHARINE II., empress of Russia, born in Stettin, May 2, 1729, died in St. Petersburg, Nov. 17, 1796. She was the daughter of Christian August, governor of Stettin, who was afterward reigning prince of Anhalt-Zerbst, and field marshal general of Prussia. Her mother was a princess of Holstein-Gottorp. Her parents gave her the names Sophia Augusta, and a careful education. At an early age she was chosen by the empress Elizabeth, at the suggestion of Frederick the Great, to become the wife of her nephew and successor, Peter III. Her mother brought her to the court of Russia, where she adopted the Greek creed, received the name of Catharine Alexievna, and was married in September, 1745. But all the expectations she may have formed of a life of magnificence, influence, and delight as future empress of the greatest monarchy of the world, soon vanished under the indifference and repulsive treatment of her husband, who, though not incapable of good emotions, was rude, dissolute, and passionate. Her fiery and lively temper could not be contented with the consolation of continued studies, in the long retirement in which she lived during the life of Elizabeth, and she indulged in amorous connections which were no secret to any one. Among the persons who surrounded Peter and herself, Soltikoff won her liveliest affection by his spirit and good looks, and lost it only when favor and envy had sent him as ambassador to foreign courts. At that time Catharine became mother of Paul, afterward her successor in the empire. The handsome and highly accomplished Poniatowski won the place of Soltikoff at his first appearance at the court, and was protected in her favors by the empress Elizabeth, who caused Augustus III., king of Poland, to appoint him as his ambassador; but he was soon persecuted by intrigues of representatives of other courts, who saw in his sympathies for England, and in his influence over Catharine and Peter, a danger for the French-Russian-Austrian alliance. He was recalled, and Gregory Orloff became the object of her favors. When Peter succeeded Elizabeth, Jan. 5, 1762, the ill feeling between him

and Catharine became still more embittered, and the conduct of both, particularly the gross public amours of Peter, gave each sufficient cause for hatred. Catharine was threatened with repudiation by her husband, and the Orloffs and their friends were ready to save and revenge her. The hetman Razumovski, Count Panin, and Princess Dashkoff, a bold and enterprising woman, became their chief assistants in the conspiracy against Peter, which was greatly promoted by the general antipathy created in the nation and army by the Prussian predilections and discipline, as well as by the character and policy of the unfortunate monarch, and was eagerly joined by malcontents, romantic adventurers, and ambitious courtiers. But the plot was nearly detected and one of the conspirators imprisoned, when they hastened its execution. In the night of July 8-9, 1762, Catharine came over from Peterhof to St. Petersburg, a part of the way on a peasant's wagon, and appeared before the guards, who hailed her as empress, though, according to the original plan, her son Paul was to be declared emperor and herself regent; but this had been changed by the Orloffs, and the future senator Teploff read, instead of the prepared manifesto, a new one in the Kazan church. Peter was soon seized, and after a few days strangled in prison. The sooner to gain pardon for her part in the crime, Catharine made the most splendid promises to the nation, flattered its prejudices, exhibited great devotion to the national religion and its priests, was crowned with great pomp at Moscow, and made a show of extraordinary zeal for improvements in industry, commerce, and the navy, and for reforms in the administration of justice, as well as in the management of the external affairs of her vast empire. Courland was compelled to depose its duke, Charles of Saxe, and to submit again to the rule of Biron, who had made himself hateful by his cruelty. Her influence prevailed in Poland after the death of Augustus III. (1763), in the election of her favorite Poniatowski as king under the name of Stanislas Augustus, from whose affection and weakness she justly expected the extension of her influence over the neighboring state, distracted as it was by religious and civil dissensions. But this happy commencement could not allay the hatred of national malcontents; attempts against the empress were plotted at Moscow and St. Petersburg, with the aim of setting upon the throne of the czars Ivan, son of Anna Carlovna, who had already atoned by 24 years of imprisonment under Elizabeth and Catharine for having worn as a child, for a few months, the imperial title before the accession of the former. The violent death of Ivan, in his prison at Schlüsselburg (1764), put an end to these schemes; and Catharine could now enjoy more easily the pleasures and festivities of her court, troubled but little by its intrigues about favors and favorites. The convocation at Moscow of representatives from all

the provinces of the empire for discussing the reorganization of justice, was a new manifestation of her political activity, as were the rules elaborated by her, and read in the first session, of her political wisdom. But the rude Samoyeds spoke of oppression by their governors, and a proposition for the enfranchisement of the serfs was soon made. Catharine was afraid of the consequences, and hastily dissolved the assembly, who declared her mother of the country. Greater were the results of her external diplomacy. Poland, undermined by her intrigues and her protection bestowed on the dissidents, soon became a prey to its neighbors. The confederation of Bar (1768), under the Pulaskis, Potocki, and other patriots, the weak opposition of France to Russia, and a declaration of war by the Turks, could not save that unhappy country; and its first division by Russia, Austria, and Prussia ensued in 1772, and Catharine received a proportionate share. The Turks were humbled by her armies under Rumiantzeff, on the Pruth and on the Kagul (1770), by the conquests of Khotim and Bender, as well as by her fleet under Alexis Orloff, which won the great naval victory of Scio, and burned the Turkish fleet in the bay of Tchesme; and the last disasters compelled the Porte to accept the peace of Kutchuk-Kainarji (1774), and to cede Kinburn, Azov, Yenikale, Kertch, and both Kabardas to Russia. The Crimea was made independent, soon to become a prey to Russia. Having happily subdued and severely punished the revolt of the Cossack Pugatcheff, a pseudo-Peter, in the eastern provinces (1771-4), she now formed the plan of expelling the Turks from Europe, and founding a new Byzantine empire under a prince of her house. This scheme, favorably regarded by some philosophers of France, was eagerly promoted by her new favorite, the ambitious Potemkin, who ruled her no less arrogantly than he did the empire. One of the gates of Moscow received this inscription, "Way to Constantinople;" one of her grandsons the name of Constantine; and plans were made on the banks of the Neva for the restoration of Sparta and Athens. After a journey through the eastern provinces which had been the scene of the revolt, she undertook a new one, in 1787, through the southern parts of her empire, to the lately conquered Taurida (in part the ancient Tauris). Potemkin made this a most magnificent triumph. The eyes of the empress were dazzled by enchantments; palaces rose on desert prairies, to shine for a day; villages and cities, of which only the walls were real, were seen from afar, covering the barren plains of the Tartar nomads; masts and flags rising above the sands showed fictitious canals; festivities and bonfires followed each other; and dances and songs, got up by official order, were supposed to show the happiness of a population of a hundred nationalities. Catharine, who delighted in the applause of the French philosophers, amused herself and her court at the same time with translating Mar-

montel's *Bélisaire*, but still pursued her diplomatic schemes. Poniatowski, who came to see her after 23 years, near the frontiers of his dismembered state, was repaid with kind promises for ancient personal affection and new political fidelity. Joseph II. of Austria, who came to Kherson, was won for a common war against Turkey, which ended for Austria with his death (1790), and without gain, and for Russia, after the conquest of Otchakov by Potemkin, after the great victories of Suvaroff, and his bloody conquests of Ismail and Bender, with the peace of Jassy (1792), and the acquisition of Otchakov and the country between the Bog and Dniester. This result, so slight in comparison with the expected overthrow of the Turkish empire, was owing in part to a war with Gustavus III. of Sweden, who marched against St. Petersburg, but was happily checked in Finland by his officers refusing to advance, and was thus compelled to make peace (1790); in part to the opposition of England and Prussia; but principally to the bravery of the Turks in defence of their country. The progress and victories of the French revolution, though giving her a kind of satisfaction by the humiliation of several states once mighty, filled Catharine with horror, and made her soon forget all her predilections for France, and her own vaunted liberalism; she assisted the *émigrés*, broke off every communication with the French government, and even made an alliance with England. Poland was in the mean time the chief object of her attention. Catharine, while at war with Turkey, had approved of its new constitution of May 3, 1791, which promised to give union and vigor to the nation, as did also Frederick William II. of Prussia, who was at war with France. But scarcely were these wars ended when Poland was treacherously attacked from both sides. A Russian army of 100,000 men was sent to support the aristocratic faction that had formed the confederation of Targovitza against the constitution. The nephew of the king, the future French marshal, Joseph Poniatowski, in vain led the Polish army against them; Kosciuszko proved in vain to be a worthy disciple of Washington. The king, persuaded by Catharine, deserted them, and went over to the confederation, and the second partition of Poland followed, executed by Russia and Prussia alone. The Russian cannon compelled the diet of Grodno to sanction it (1793). The great rising of the betrayed nation in the following year commenced with the massacre of the Russians, and with glorious victories under Kosciuszko as dictator, but ended with his defeat at Maciejowice (Oct. 10, 1794), and with the taking of Praga (Nov. 3) by Suvaroff, who repeated there the slaughter of Ismail and Bender. "Bravo, field marshal!" was Catharine's answer to his report, "Hurrah, Praga—Suvaroff." The three great neighbors of Poland now took the whole of it, and destroyed even its name (1795). A year before Catharine had annexed Courland to Russia. She

next undertook a war against Persia, but died of apoplexy, after an agony of 30 hours, leaving her empire, so greatly enlarged, to her son Paul.—Catharine was possessed of great talents, susceptible of great ideas, and showed often a manly spirit and energy; her ambition appeared grand; but at the same time she was a woman in caprice, a slave of her sensuality and vanity, extremely selfish, and sometimes cruel. Her numerous favorites, some of them her tools and some her masters, were elevated by their official situation in the palace, by privileges, promotions, and presents, to dignity in the state; while she was, on the other hand, prompted by the love of glory to flatter the representatives of public opinion, particularly in France, to invite Voltaire to her court, to call D'Alembert to complete the French *Encyclopédie* in St. Petersburg, to suffer the familiarities of Diderot, to have a regular literary agent (Grimm) in Paris, and to write herself several books in French; to promote literature and art, industry and agriculture, in her empire; to reform its laws, and attempt the abolition of many abuses; to build fortresses, cities, canals, hospitals, and schools; to organize exploring expeditions on land and sea; to annex and to conquer. She had the satisfaction of being called the Semiramis of the North, of being ranked by philosophers with Lycurgus and Solon, of hearing the words of Voltaire, "Light comes now from the North." But her fame was only a transient applause; her reforms, undertaken for show, vanished without result; most of her works came to nothing before she died; and her civilization did more to corrupt Russia than to elevate it.—Lives of Catharine II. were written by Castéra, J. G. von Struve, and Tannenber; and Hertzgen published in London (1859) *Mémoires de l'impératrice Catherine II. écrits par elle-même et précédés d'une préface.*

CATHARINE OF ARAGON. See HENRY VIII.

CATHARINE OF BRAGANZA, queen of England, born in 1638, died Dec. 31, 1705. She was the daughter of John IV., after 1640 king of Portugal, and in 1662 married Charles II., king of England, bringing her husband, besides a rich dowry, Tangiers in Africa and Bombay in India. She had been bred in a convent, and was not accustomed to the free conversation and licentious manners which prevailed at the court of her husband. Her influence was unavailing to produce any change, nor was she able to restrain the dissolute conduct of the king or to gain his love. In 1678 accusations against her of plots in favor of the Catholic religion were received favorably by the house of commons, but rejected by the lords. After the death of Charles (1685), she was treated in England with attention and respect. She returned to Portugal in 1693. Made regent of that country by her brother, Dom Pedro, in 1704, she proved her ability in the war with Spain, which she carried on with success, though 67 years old.

CATHARINE FIESCHI ADOBORNO, Saint, born in Genoa in 1447, died Sept. 14, 1510. Her father was viceroy of Naples. At the age of 13 she desired to consecrate herself to God in the religious state; but in obedience to her parents she married at the age of 16 Julian Adorno, a gay young nobleman of Genoa. Her life with him was for ten years a series of sorrows, sufferings, and mortifications. He was profligate, brutal, and prodigal in the use of the fortune which she brought him. In a short time they found themselves reduced to poverty; but her patience and good example caused his reformation, and he died a penitent. After his death Catharine was for many years mother superior of the great hospital of Genoa, and extended her care to the sick and suffering throughout the city. St. Catharine, next to St. Theresa, is the most profound female writer that the Roman Catholic church has produced. Her two principal treatises, which for the most part may be considered as the records of her own experience, are entitled "Purgatory" and "Dialogue between the Soul and the Body." She was canonized in 1737 by Clement XII., and her anniversary is celebrated on Sept. 14. An American translation of her treatises and of her life, written by her confessor, Marabotto, appeared in 1858.

CATHARINE OF FRANCE, or of Valois, queen of England, born in Paris, Oct. 27, 1401, died in the abbey of Bermondsey, England, Jan. 3, 1438. She was the youngest child of Charles VI. of France and Isabeau of Bavaria. Henry V. of England, having asserted his claim to the crown of France, applied for her hand, but demanded an enormous dowry in money and the cession of Normandy and several other provinces. The court of France declining these terms, Henry V. invaded the country, and, after the victory of Agincourt and the capture of Rouen, renewed his application, which was this time favorably entertained. By the treaty of Troyes, May 21, 1420, it was agreed that Henry should receive the hand of Catharine and succeed to the throne of France after the death of Charles VI., the regency of the kingdom being placed in his hands until that time. They were married at Troyes, June 2, with great ceremony, and in the following year sailed for England, where Catharine was crowned Feb. 24, 1421. Henry, being obliged to return to France, left his young wife in England, where she gave birth on Dec. 6 to a son, afterward Henry VI. She was soon recalled to France, where she found her husband dying. Immediately after his death (Aug. 31, 1422), his infant son was proclaimed king of France and England. A few years later, but when is not certainly known, Catharine was secretly married to Owen Tudor, a young and handsome Welsh knight of good family, who had fought at Agincourt, and after holding the office of squire of the body to Henry V. had become clerk of the wardrobe to Catharine. By this husband she had three sons, the eldest of

whom, Edmund of Hadham, so called from Hadham house, where he was born, was made earl of Richmond by Henry VI., who also procured his marriage with Margaret Beaufort, the heiress of the house of Somerset. The issue of this marriage was a son, afterward Henry VII., the first sovereign of the house of Tudor. The marriage of Queen Catharine with Owen Tudor does not seem to have been discovered till a few months before her death. She was sent to a convent and Tudor to Newgate jail, whence he escaped to Wales, and after some years was taken into favor by Henry VI., in whose service he fought against Edward IV., by whom he was taken prisoner and put to death in 1460.

CATHARINE DE' MEDICI, queen of France, born in Florence in 1519, died at Blois, France, Jan. 5, 1589. She was the only daughter of Lorenzo de' Medici, and in 1533 Pope Clement VII., her uncle, negotiated her marriage with Henry, duke of Orleans, second son of Francis I. Entering the court of France in a somewhat secondary position, she applied herself to conciliate all parties, win all affections, and be everything to all persons, affecting in the mean time to care nothing for affairs of state and to shun the turmoil of business. When she came to France, the duchess d'Étampes and the celebrated Diana of Poitiers, afterward duchess of Valentinois, were ostensibly the mistresses of her father-in-law, the king, and of her husband; and to both she assiduously paid her court, though they notoriously hated one another. His elder brother, the dauphin, having died, Henry in 1547 succeeded his father as king of France. Catharine, however, did not alter her policy or interfere, whether in the affairs of state or in his social and domestic arrangements, with her husband, or with his mistress. In 1559 Henry was accidentally killed at a tournament held at the castle of Tournelles; and his son, Francis II., a delicate stripling, weak both in health and intellect, lately espoused to Mary Stuart, queen of Scots, who was on her mother's side a Guise de Lorraine, succeeded to the throne. During his short reign Catharine did not exercise much influence at court, for the king was completely under the rule of his wife and her maternal uncles, the celebrated Le Balafre, Francis duke of Guise, and the cardinal Lorraine, who were not favorable to the schemes of the queen mother. Catharine, who cared nothing for religion, connected herself with the Huguenot leaders, Condé, Coligni, and the king of Navarre, and a plan was laid for seizing and imprisoning the young sovereigns at Amboise, bringing the Guises to the scaffold, and governing the realm by a council of regency, composed of the Huguenot princes under the guidance of Catharine. The plot, however, was detected; the princes were compelled, in order to avoid the suspicion of complicity in the conspiracy, to witness the slaughter of their partisans; while Catharine immediately deserted

them, and joined the party of the Catholic league. The next plan was to assassinate the duke of Condé in the presence of both Francis and Mary at Orleans, which city they were about to visit in state, on a royal progress; and on Francis positively refusing to give his assent to the murder, one of the Guises is said to have exclaimed, "Now, by the double cross of Lorraine, but we have a poor creature for our king!" Francis II. died soon after, and such was the condition of court morals at the time that his death was attributed to poison, dropped into his ear while sleeping, not without the privity of Catharine, who by the accession of Charles IX., a minor, succeeded as regent (1560) to the actual if not the nominal sovereignty of the realm. She now gave full swing to her atrocious genius. She first plunged all her children into such licentious pleasures and voluptuous dissipations, that they were speedily unfitted for mental activity or exertion. On the occasion of the marriage of her daughter, Marguerite of Valois, with Henry of Navarre, Catharine prevailed on Charles to give the orders for the fatal massacre of St. Bartholomew's, an event which greatly increased her power, of which she boasted to Catholic governments, and which she excused to Protestant ones. Charles IX. died in 1574, and the belief was that he had been poisoned by his brother Francis, duke of Alençon, with the connivance of his mother. Her son Henry of Valois, then in Poland, of which he had been elected king by the diet, left that country secretly, returned to France, and claimed the throne. During his reign, which ended Aug. 2, 1589, Catharine had until her death a principal but concealed share in the plots and party contests which distracted France. She is supposed to have instigated the death of Henry of Guise and his brother the cardinal, who were assassinated by the king's order. This was the ruin of Henry and of the schemes of Catharine. It united all Catholic France against the king, brought about his death by assassination, and made her an object of aversion to all parties. She died unheeded in the fierce strife of wars which she had stirred up.

CATHARINE PARR, queen of England, the sixth and last wife of Henry VIII., born at Kendal castle, Westmoreland, about 1513, died at Sudely castle in Gloucestershire, Sept. 7, 1548. She was the daughter of Sir Thomas Parr, who was at the time of her birth master of the wards and comptroller of the king's household. He died when she was but five years old, leaving her education in charge of her mother, under whose tuition and care Catharine became one of the most learned and accomplished women of her time. She was married when very young to Edward, Lord Burgh, an elderly widower, who died in 1528. Shortly after this the family of the Parrs, already distantly connected with the royal house, became more nearly allied with it through the marriage of Catharine's brother William to a

kinswoman of the king; and two of the Parris now became attached to the court. These circumstances seem to have led at this early day to some degree of friendly intercourse between Henry and Catharine. While still under 20 years of age she was married again, this time also to a widower, John Neville, Lord Latimer, an earnest Catholic, who died in 1542 or 1543. Soon after his death Catharine embraced the Protestant faith, of which she became from this time an earnest friend and defender, her home at Snape hall being a resort of some of the most famous reformers. During this second widowhood her hand was sought by Sir Thomas Seymour; and she had already consented to marry him, when she received the alarming and unwelcome news that she had been selected for the sixth wife of the king. It was impossible to resist the royal will, and Catharine was married to Henry on July 12, 1543. The influence of the new queen at court was excellent. She behaved toward Henry with the greatest tact, and used his favor, which she successfully retained, for the best purposes, even venturing to occasionally interfere in behalf of persecuted Protestants. She devoted much of her time to study, composition, and scholarly pursuits, and impressed the importance of these upon the king's children. Her relatives received places of influence, and she so skillfully managed her husband's caprices as to gain some power even in state affairs. When Henry went to France in 1544, he left her regent of the kingdom. Even her known sympathy for the unfortunate Anne Askew did not suffice to turn the fickle king against her; and it was a comparatively trivial matter which brought her into her first real danger of sharing the fate of her predecessors. In one of the theological discussions in which she occasionally engaged with Henry, she allowed herself to support her views with more warmth than usual, and he became greatly incensed. One of her Catholic enemies who was present took advantage of the king's anger to poison his mind against the queen, and, aided by others, induced him to permit several of his councillors to consult as to the drawing up of a warrant against her. This warrant and an order for her arrest were actually signed a few days later; but Wriothesley, the lord chancellor, to whom they had been given, accidentally dropped them, and they were found and carried to Catharine. Thus warned, she so skillfully flattered and soothed her husband that he became completely reconciled to her. He saluted Wriothesley, when he came to arrest the queen, with a torrent of abusive epithets, and bade him "avaunt from his presence." From this time Catharine enjoyed apparent favor till Henry's death in 1547; but there seems little doubt that in secret the king considered several plans for ridding himself of her. She did not long remain a widow. After passing a few months in her jointure house at Chelsea, she became the wife of her old lover Sir Thomas Seymour, now

lord admiral. But her married life with him was embittered by his familiarity with the young princess Elizabeth, and by his growing neglect of herself. Though without children by her former marriages, she bore Sir Thomas a daughter on Aug. 30, 1548, the infant's birth costing her her life.—Catharine's literary works are admirable specimens of a pure early English style. She wrote "Queen Catharine Parr's Lamentations of a Sinner," published by Lord Burleigh in 1548. In her lifetime she published a volume of prayers and meditations. Her letters are preserved in Strype's annals, Hayne's collection of state papers, and in the Ashmole collection. She employed scholars to translate from the Latin into English Erasmus's paraphrase on the New Testament, and wrote a Latin letter to the princess, afterward Queen Mary, exhorting her to translate the paraphrase on St. John.

CATHARINE PAULOVNA, queen of Württemberg, grand duchess of Russia, daughter of Paul I. and younger sister of Alexander I., born May 21, 1788, died Jan. 9, 1819. In 1809 she married George, duke of Holstein-Oldenburg, who died in 1812. She accompanied her brother Alexander on his campaigns in Germany and France (1813-'14), and to Paris, London, and the congress of Vienna (1815), assisting him by her talents and resolute spirit. In 1816 she married William, crown prince of Württemberg. During the famine of 1816 in that country she proved her benevolence by the formation of female associations and an agricultural society. She was active in promoting the education of the people. She left two sons by her first and two daughters by her second marriage.

CATHARINE OF SIENA, *Saint*, born at Siena in 1347, died in Rome, April 29, 1380. She entered at 20 years of age the order of Dominican nuns, and became distinguished for her charity and devotion. She restored the Florentines to the favor of Gregory XI., and exhorted that pontiff to leave Avignon for Rome. She wrote in defence of Pope Urban VI., when his authority was contested by Clement VII. She was canonized by Pius II. in 1461, and her anniversary is celebrated on April 30. The works of this saint are principally treatises upon devotional subjects, letters, and poems, collected in *Opere della serafica Santa Catharina* (4 vols., Siena and Lucca, 1707-'13).

CATHARISTS, or *Cathari* (Gr. καθάρως, pure), a name assumed by heretics of the middle ages to justify their opposition to the alleged corruptions of the Roman Catholic church. They were also called in Italy Patavini or Paterini, in France Publicani, and at a later period Bulgarians; and from the time of the Albigensian war the name Albigenses became more common than any other. (See ALBIGENSES.) According to some, the Catharists appeared as early as 1035 near Turin, but the first undisputed trace of them is in 1101 at Agen. They spread from southern France into the neigh-

boring countries. Their central point in France was Toulouse, and in upper Italy, Milan. In order to secure uniformity of policy and doctrine, they held in 1167 a synod at Toulouse, at which even a Catharist bishop of Constantinople, Nicetas, was present. As they were protected by a considerable number of the nobles, the decrees of the popes and councils against them remained without effect, and a crusade against them in 1181, headed by the cardinal legate Henry, abbot of Clairvaux, was likewise unsuccessful. At the close of the 12th century a branch of the sect passed from Dalmatia into Bosnia, where they became very numerous. In southern France they even became the dominant party, but the issue of the protracted and bloody Albigensian war left them without patrons and at the mercy of the inquisition. Nevertheless they maintained themselves in southern France till the 14th century, increased in upper Italy and in Bosnia and Bulgaria, where they appear to have for some time been in the ascendant, and spread more or less into other European countries. In England, where they made their appearance in 1159, they were quickly suppressed. In most other countries they succumbed to the inquisition and to crusades in the first half of the 14th century. In Bosnia, however, they became once more predominant, under King Stephen Tvartko, as late as 1376, and in southern France and the Basque provinces the Cagots traced their origin to the Albigenses.—Our knowledge of the Cathari is almost exclusively derived from Roman Catholic writers, and chiefly from the inquisitors, who had the mission, if necessary, to exterminate them by fire and sword. Their reports frequently differ. According to some writers, they were distributed into three chief divisions: the Albigenses, who professed dualism, and the Concorrezenses and Bagnolenses, who assumed one supreme principle. Others do not give any of these names, and merely distinguish between the dualistic Cathari and the adherents of one supreme principle. The former assumed two opposite principles, without beginning and without end; the latter believed in one supreme God, but generally rejected the doctrine of the Trinity. All parties appear to have regarded Satan as the creator of the visible world, and as the Jehovah of the Old Testament. From him, in the opinion of the Catharists, the greater portion of men derive their origin, and they cannot be redeemed; but there is also a higher class of men, whose souls are the fallen angels, and for the redemption of whom the God of light sent the angel Jesus, who taught them that they were of a higher nature, and that by despising everything material they could emancipate themselves from the prince of this world. The ancient system of the strict dualists is said to have been considerably modified about 1230 by their bishop Johannes de Lugio, who taught that good and evil had limited each other from eternity, and had already intermingled in the

world above. The Cathari rejected all the fundamental doctrines of the Catholic church, as the Trinity, incarnation, and resurrection. They renounced baptism by water, and laid great stress on the baptism of the Spirit, which should be performed by the imposition of hands in connection with prayer. Their church edifices had neither images, cross, nor bell, and the worship consisted only of the reading and exposition of a passage of the New Testament, followed by the benediction. Marriage was classed among the mortal sins, inasmuch as it increases the number of fallen souls. One of the most important rites of the sect was the *consolamentum*, consisting of the imposition of hands and the putting on of a garment; by means of this rite the members also advanced into the higher class of the *perfecti*, which had to practise the most rigorous asceticism, while those of the lower class (*credentes*) are said to have been at liberty to give themselves to a licentious life, provided they vowed to enter at some future time the higher class. Their hierarchy consisted of four degrees, the highest of which was that of the bishop. Some are of the opinion that a pope stood at the head of the hierarchy.—Besides the New Testament, the Cathari held the apocryphal book *Visio Isaie* in high estimation. A Catharist translation of the New Testament in a Romaic dialect, with an appendix containing a short liturgy, an act of confession, acts of reception among the *credentes* and among the *perfecti*, some special directions for the faithful, and an act of consolation in case of sickness, was discovered in 1851. The best works on the Catharists are Schmidt's *Histoire et doctrines de la secte des Cathares* (2 vols., Paris, 1849) and Hahn's *Geschichte der Ketzerei im Mittelalter* (2 vols., Stuttgart, 1845-'50).

CATHARTICS (Gr. καθαρτικός, from καθαίρειν, to cleanse), medicines used to promote evacuation of the intestines. Their number is very large, and they may be divided into several classes, such as mechanical, including unbolted meal of various kinds, fruits, and mustard seed; oily, as croton and castor oil; saline, as magnesia and its carbonate, sulphate, and citrate, sulphate and phosphate of soda, bitrate of potassa, &c.; acid or bitter, as rhubarb, senna, colocynth, and aloes; resinous, as jalap, scammony, gamboge, and podophylline; and mercurial, calomel and blue pill. Their action varies, partly with the dose, from the mild and almost natural effect of magnesia and aloes, to the violent purging of jalap, gamboge, or elaterium. For a more detailed statement of individual peculiarities, see the several titles.—The *modus operandi* of cathartics is chiefly in stimulating the intestines to more active contraction, and thus either hastening the discharge of the more watery contents of the upper bowels, before they have time to experience the loss of fluid which usually takes place by absorption in the large intestine, or else unloading the colon of its normal contents. The saline cathartics are probably always absorbed

to some extent, and if they fail to act upon the bowels may be eliminated in part or wholly by the urine. Some of the others, as senna and scammony, demonstrate their occasional absorption by causing purgation in infants when taken by the nurse. The coloring matter of rhubarb sometimes appears in the secretions. —Cathartics are very largely used, both singly and in the most various combinations with each other and with tonics and aromatics, from the natural salines of mineral springs to the numerous quack compounds with which the country is flooded. They are probably more abused than any other class of drugs, since a resort to them is so easy as to often lead to a neglect of highly important hygienic rules. They should never be allowed to take the place of due attention to diet, exercise, and habit. The common use of powerful cathartics at the beginning of acute diseases, to "work off a cold" for instance, is as a rule to be deprecated. Their use, however, is often necessary, not only to relieve constipation, but to withdraw water primarily from the intestinal canal, and secondarily from other parts of the body, as in dropsy, or to control the circulation by calling a large amount of blood into the capacious veins and arteries of the abdomen. The uterus, from its nearness to the bowel, may be injuriously affected by the action of violent purges.

CATHCART, William Schaw, earl, a British general and diplomatist, born at Petersham, Sept. 17, 1755, died at Cartside, near Glasgow, June 17, 1843. He was the eldest son of the 9th Baron Cathcart, studied law, although without intention of practising that profession, and on the breaking out of the American war entered the British army, where he speedily rose to be aide-de-camp to Gen. Spencer Wilson and Sir Henry Clinton. Subsequently he commanded the 29th regiment of infantry, and finally was appointed quartermaster general. Recalled to England, he joined the Walcheren expedition with the rank of brigadier general. After distinguishing himself at Bommel and elsewhere on the retreat, he returned to England, where he was promoted. In 1807 he took his seat as a representative peer of Scotland. The same year he was appointed commander-in-chief of the troops destined to act against Copenhagen, and on the fall of that city and capture of the Danish fleet was created a peer of England as Viscount Cathcart and Baron Greenock. In 1812 he was sent as minister plenipotentiary to Russia. The emperor Alexander being then with the army, Lord Cathcart joined him at headquarters, where he remained during the campaigns of 1813 and 1814. He entered Paris with the allied sovereigns, subsequently acted as British plenipotentiary at the congress of Vienna, and was made an earl, June 18, 1814. On the final overthrow of Napoleon he again repaired to Paris and signed the treaty of peace which followed Waterloo. He was afterward for some time minister to Russia. His later

years were passed at his country house of Cartside.

CATHEDRAL (Lat. *cathedra*, a seat), a church containing a bishop's throne or seat, the chief church of the diocese. Its usual form is a Latin or Greek cross, and it is not distinguished architecturally from the basilica. In the old basilicas there was a transverse hall at the end, not intentionally resembling a cross; but more modern architects, perceiving the resemblance, changed the position of the transept, making the church cruciform. The church of St. John of Lateran at Rome, founded by Constantine, is the episcopal church or cathedral of the pope, and bears over its chief portal the inscription, *Omnium urbis et orbis ecclesiarum mater et caput*, "Mother and head of all the churches of the city and the world." At its chief altar none but the pope can read mass, for it covers another ancient altar at which the apostle Peter is said to have officiated. The basilica of St. Peter's at Rome is surpassed by no cathedral in antiquity and splendor, and equalled by none in magnitude. In the year 90 Anacletus, bishop of Rome, who was said to have been ordained by St. Peter himself, erected an oratory on the site of the apostle's burial, after his crucifixion. In 306 Constantine built a basilica on the spot. In 1450 Nicholas V. commenced a building on plans of Bernardino and others. Paul II. continued it, and Julius II. secured the services of Bramante, whose plan was a Latin cross and an immense dome on arches springing from four large pillars. The latter died in 1514, and Leo X. appointed Giuliano Sangallo, Giovanni da Verona, and Raphael, who strengthened the pillars for the dome; but Sangallo dying in 1517, and Raphael in 1520, Leo employed Baldassari Peruzzi, who changed the plan to a Greek cross. Paul III. employed Antonio Sangallo, who returned to Bramante's plan; but he died very shortly, and the pope appointed Giulio Romano, who also died. The work was then given to Michel Angelo, then in his 72d year. Paul III. died in 1549, but Julius III. continued Michel Angelo in his place, giving him full authority to change whatever he wished in the building as it then stood. He returned to the Greek cross, and strengthened the piers for supporting the dome. The drum of the dome was completed before he died in 1563. Pius V. appointed Vignola and Pirro, with orders that they should adhere to Michel Angelo's plans. The present dome, finished in 1590 by Giacomo della Porta, is lighter and higher than that designed by Raphael. Sixtus V. gave 100,000 gold crowns annually toward its completion. In 1605 Paul V. employed Carlo Maderno, who changed the ground plan back to the Latin cross. The nave was finished in 1612, the façade and portico in 1614. The church was dedicated by Pope Urban VIII. on Nov. 18, 1626. Under Alexander VII., in 1667, Bernini finished the colonnade. The building of St. Peter's, from its foundation in 1450 till its dedication, occupied 175 years;

and if we include the work done under Pius VI., three and a half centuries passed before it was completed, during which time 43 popes reigned. The dimensions of the church are as follows: length of the interior 613½ English ft., of transept from wall to wall 446½ ft.; height of nave 152½ ft., of side aisles 47 ft.; width of nave 77–89 ft., of side aisles 33½ ft.; circumference of pillars which support the dome 253 ft. The cupola is 193 ft. in diameter. The height of the dome from the pavement to the base of the lantern is 405 ft., to the top of the cross 448 ft. The dome is encircled and strengthened by six bands of iron. A stairway leads to the roof, broad and easy enough to allow a loaded horse to ascend. The annual cost of keeping the church in repair is 30,000 scudi.—At Milan the first cathedral was destroyed by Attila; the next one was injured by fire; and the first stone of the present structure was laid by Giovanni Galeazzo Visconti on March 15, 1387. The ground plan is a Latin cross terminated by an apsis. Its dimensions are: length 486 ft.; breadth of body 252 ft., between the walls of the transept 288 ft.; width of nave from centre to centre of the columns 63 ft., which is double the width of the side aisles; height of the crown of the vaulting of nave 153 ft.; height from the pavement to top of the statue of Madonna 355 ft. The interior is divided into a nave and four aisles, by four ranges of clustered pillars. Fifty-two pillars, each formed of eight shafts, support the arches of the roof. These pillars are 80 ft. high, viz.: a base 4 ft., shaft 57 ft. 6½ in., capital 18 ft. 6½ in.; diameter of shaft 8 ft. There are fine interior doorways in Roman style. The pavement is laid in mosaic in red, blue, and white marble. The white marble exterior has niches and pinnacles for 4,500 statues, of which over 3,400 are completed at present.—The duomo at Florence is one of the most beautiful specimens of the Italian-Gothic style. It was begun in 1298 upon the plan of Arnolfo di Cambio da Calle, and was finished about 1444. Several architects were employed upon it, among them Giotto, Taddeo Gaddi, and Andrea Orgagna. Its completion was intrusted to Brunelleschi, who designed the cupola. The cathedral is in length 500 ft., the transept 306 ft.; the nave is 153 ft. high, the side aisles 96 ft. 6 in. The cupola is octagonal in form, 138 ft. 6 in. in diameter, and in height from cornice of the drum to the eye of the dome 133 ft. 6 in. Michel Angelo used this dome as a model for that of St. Peter's. The interior of the duomo is rather dark, the windows being small and the glass darkly stained. The pavement is tessellated in red, blue, and white marble. The frescoes in the cupola are from designs by Vasari. The entire edifice covers 84,802 sq. ft.—The cathedral at Cologne, begun about the middle of the 13th century, is one of the most imposing Gothic structures in Europe. The original architect is unknown. The choir was not consecrated till 1322, and the north and south aisles of the

nave had only been carried up to the capitals of the columns in 1509, and were covered with a wooden roof. Work was suspended till 1830. In 1842 Frederick William IV. laid the first stone of the transept, which with the north and south portals was finished before 1863, when the whole interior was thrown open. The length of the cathedral is 511 ft., breadth 231 ft., and the towers will be 511 ft. high. Externally it has a double range of flying buttresses and intervening piers, and a perfect forest of pinnacles.—The cathedral of Dantzic was begun in 1343 and finished in 1503. It is of brick, and 358 ft. long. The vaulted roof is 98 ft. high, supported by 26 slender brick pillars. Around the interior are 50 chapels founded by citizens of the place as family burial places. The great ornament of this building is a painting of the "Last Judgment," attributed to Jan van Eyck. According to tradition, it was painted for the pope, but on its way from Bruges to Rome was captured by pirates. Being retaken by a Dantzic vessel, it was deposited in the cathedral in 1467.—The cathedral of Notre Dame in Antwerp is one of the largest and most beautiful Gothic buildings in the Netherlands. It was commenced between 1352 and 1411. The west front and tower are of the 15th century. It is 390 ft. long and 250 ft. wide. In 1566 it was sacked and much injured. It contains the celebrated masterpiece of Rubens, the "Descent from the Cross."—The cathedral at Rheims was commenced in 1211 and the choir dedicated in 1241. It was completed in 1430, and is 466 ft. long. The cathedral at Amiens was begun in 1220; it is 469 ft. long, and has a central spire 422 ft. high, which dates however only from the 16th century.—The cathedral at Strasburg, one of the grandest Gothic churches in Europe, is remarkable for its spire, designed by Erwin of Steinbach. The work was half finished in 1318, when he died, and was continued by his son and afterward by his daughter Sabina. It rises 468 ft., and is an open fretwork of stone bound together by iron ties. The tower was completed in 1439, but a second tower, which the cathedral was intended to have, is still unfinished, and mars somewhat the effect. During the siege of the city by the Germans in 1870 it was badly injured by shells and other projectiles.—The cathedral of Notre Dame in Paris stands upon the spot once occupied by a Roman temple. It is said that a church dedicated to St. Stephen was erected on the same site about 365, in the time of Valentinian I., and was enlarged in 522 by Childebert, son of Clovis. Robert, son of Hugh Capet, undertook to rebuild this church, which was called Notre Dame from a chapel which Childebert had dedicated to the Virgin. But this church was never finished and fell into ruins. The first stone of the present edifice was laid about 1163, by Pope Alexander III., Maurice de Salliac being bishop of the diocese. The high altar was consecrated in 1182 by Henry, legate

of the holy see, and in 1185 Heraclitus, patriarch of Jerusalem, officiated in the church. The west front was finished by Maurice de Sully, the bishop, in 1223. The southern transept with its portal was completed in 1257, and the northern transept and portal in 1312 by Philip the Fair. The western doors with their iron work were made about 1570-80 by Biscourette. The dimensions are as follows: length 390 ft., width of transept 144 ft., height of vaulting 105 ft., height of western towers 224 ft., width of front 128 ft., length of nave to transept 186 ft. The pillars of the nave are 4 ft. in diameter, resting on gravelled beds 18 ft. below the surface. The style of architecture is pure pointed. The nave and side aisles are paved with marble; the aisles around the choir are paved with stone and black marble. An immense vault, extending the entire length of the nave, was constructed in 1666 for the interment of chaplains, &c. The organ is 45 ft. high, 36 ft. wide, and has 3,484 pipes. The interior of Notre Dame is not so rich in decorations as the exterior. The arches of the nave are pointed; the piers are circular pillars, with large and well formed capitals. The pillars of the aisles are alternately circular and clustered. The cathedral covers 64,108 sq. ft.—England has many cathedrals worthy of particular mention. That at Salisbury is the most perfect and beautiful specimen. It was founded by Bishop Richard Poore in the year 1220, in the reign of Henry III., and was finished in 1260. Its plan is a double cross, in extreme length 442 ft., length of greater transept 203 ft. The cathedral at Canterbury dates from shortly after the Norman conquest. It was built on the site of an earlier cathedral, and modelled after that of St. Stephen at Caen, from which plan subsequent alterations have deviated. It has three towers, one in the centre and two at the west end. The northwestern tower, of Norman date, was replaced by a new one in 1832. The centre tower, which is 235 ft. in height, was begun toward the end of the 15th century. The cathedral is 574 ft. long and the greater transept 159 ft. The crypts, which extend under the entire building, are the finest in England. The interior of the eastern part, known as Becket's corona, had but recently been finished when the cathedral was partly destroyed by fire in 1872. Ely cathedral is 517 ft. in length and 190 in breadth, and has a nave 203 ft. long, 81 wide, and 74 high. The style of the building externally is Norman and early English. The centre tower and lantern, 270 ft. high, supported on eight large piers, is a remarkable feature. Lincoln cathedral is one of the most perfect examples of the early English style. It is 524 ft. long outside, and 482 inside. The greater transept is 250 ft. long outside by 222 inside. The chief tower is 300 ft. high. The cathedral at York is irregular in plan, and its parts are of different date, yet its aspect is imposing from its grand dimensions. It is 524 ft. long, 222 wide, and has

a superb centre tower. The nave, from door to choir, is 264 ft. long, and is 106 ft. wide and 93 high. It has a small crypt, a consistory court, and an elegant octangular chapter house, which leads from the north transept. St. Paul's, London, was commenced in 1675, Sir Christopher Wren being the architect, and was finished in 1710. It is built of fine Portland stone, in the form of a Latin cross, its length being 500 ft., the transept 285 ft. long, and the west front 180 ft. wide. The campanile towers at the west front are each 222 ft. high. The dome is 365 ft. from the ground, and 356 from the floor of the church, and it is 145 ft. in diameter. Simple ratios exist between the principal dimensions. The windows are mainly 12 ft. wide by 24 high, the aisles 19 ft. clear width by 38 in height; the central avenue is 41 by 84 ft.; the domed vestibule at the west end is 47 ft. square by 94 ft. high. The architectural elevation has two orders, the lower being Corinthian and the upper composite. The interior lacks in ornament, disappointing one who has seen the cathedrals on the continent. A still graver defect is the darkness under the dome, the light being scantily admitted and not well distributed. It was begun and finished under one architect, with a few mean exceptions. The organ was built in 1694 by Bernard Smydt. St. Paul's is the fifth in size of the great churches of Europe, being smaller than St. Peter's and the cathedrals of Florence, Milan, and Amiens.—In America, the cathedral of St. Peter and St. Paul at Philadelphia was commenced from designs by Le Brun in September, 1846, and opened for worship in 1862. It is built of red stone after the style of the modern Roman cruciform churches. The dome is 210 ft. in height. It has a fine organ, frescoes, and an altarpiece by Brumidi. At Baltimore the Catholic cathedral is built of granite, and is 190 ft. long, 177 ft. broad, and 127 ft. high from the floor to the top of the cross which surmounts the dome. It has a large organ of 6,000 pipes and 36 stops, a painting presented by Louis XVI., and one the gift of Charles X. of France. St. Patrick's cathedral, New York, now building (1873), was projected by Archbishop Hughes, who laid the corner stone, Aug. 15, 1858. The material is a brilliant micaceous marble, which is especially well adapted to the decorated Gothic style of architecture chosen for the work. It is 332 ft. in length and 132 ft. in general width, with an extreme width at the transepts of 174 ft. There will be two towers 328 ft. high. The cathedral of Notre Dame in Montreal is 255 ft. long and 135 broad, and is capable of seating 10,000 persons. It has two towers, each 220 ft. high, one of which contains a chime of bells and the other a single bell, the *Gros Bourdon*, weighing 29,400 lbs. There are cathedrals, some of them of imposing architecture, in several cities of southern America. That in Mexico, begun in 1573, completed in 1667, is built in an irregular mixture of the Gothic and Italian styles, and is

500 ft. in length and 420 in breadth. That of Lima is a massive stone structure, 320 ft. long and 180 wide, the façade painted red and yellow, with lath and plaster towers at each angle.—Notices and illustrations of the principal cathedrals throughout the world will be found under the names of their respective places.—See "Essays on Cathedrals," edited by J. S. Howson (London, 1872).

CATHELINEAU, Jacques, generalissimo of the Vendéans in the revolt of 1793 against the revolutionary government of France, born at Pin-en-Mauges, in Anjou, Jan. 5, 1759, died at St. Florent, July 11, 1793. After having been engaged in the business of his father, who was a mason, he became a linen peddler, and after the outbreak of the French revolution was poor, with a large family. His religious devotion was so well known in the province, that he was called the saint of Anjou. A bloody fight that took place at St. Florent, March 12, 1793, between the republican troops and the royalists, on the occasion of a levy for the army according to a recent decree of the convention, roused the spirit of Cathelineau, and at the head of a body of youth he attacked and expelled the garrisons of Jallais and Chollet. As the number and courage of his bands, though without regular arms, were continually increasing, he fought several engagements, mostly with success. After the taking of Saumur, June 13, he was elevated to the dignity of general-in-chief, as the most popular of the leaders. He marched against Angers, which made no resistance; but an attack on Nantes ended, after a whole day of desperate struggle (June 29), in the dispersion of his troops. Cathelineau was wounded and carried to St. Florent, where he died after 12 days. After the restoration of the Bourbons his surviving children were rewarded with pensions, and a statue was erected to his memory at his birthplace, which was broken in 1832 by the soldiers of Louis Philippe.—His son, also named Jacques, born March 28, 1787, took part in an anti-Napoleonic movement in La Vendée in 1815, and was shot in 1832 while engaged in the conspiracy of the duchess of Berry.

CATHOLIC CHURCH. See ROMAN CATHOLIC CHURCH.

CATILINE, or *Catilina*, **Lucius Sergius**, a Roman conspirator, killed in the engagement of Fæsulæ, 62 B. C. He was the descendant of an ancient but decayed patrician family, and is said by his enemies to have spent his youth and early manhood in a career of profligacy and crime, taking a bloody part in the proscriptions of Sulla, when even some of his own relations became his victims. He was suspected of criminal intercourse with a vestal, and believed guilty of the secret murder of his first wife and his son, committed in order to marry another woman. All this did not prevent him from obtaining important offices and aspiring to the highest dignities in the republic, being able by his mental and bodily powers,

of which even his enemies speak with admiration, to undertake every task. Having been sent as prætor to Africa, he returned in 66 B. C. to Rome, to become a candidate in the next consular election, but was disqualified by a charge of extortion in his province, directed against him by Clodius Pulcher, known by his later enmity to Cicero. The newly elected consuls were convicted of bribery, and Cotta and Torquatus, their accusers and competitors, took their places. On these Catiline resolved to wreak his vengeance, conspiring against their lives with Autronius, one of the deposed consuls, Cn. Piso, and others. The first day of the consulship was fixed for the assassination, but Catiline, it is said, frustrated the attempt by his impatient haste in giving the signal. This failure only stimulated him to greater undertakings. He now, it is alleged, formed a new conspiracy with the purpose of exterminating the whole body of the senate, murdering all the magistrates of the republic, and sharing its sway and treasures with his followers. Such is the representation of great contemporary writers, though their impartiality may be questioned. The corruption of the times favored his designs; ruined nobles of all ranks, profligates, and intriguing persons of both sexes, joined him; many veterans of Sulla were found ready to renew the familiar scenes of proscription; the restless populace could easily be used. His chief coöperators were P. C. Lentulus and P. Autronius, ex-consuls, L. Calpurnius Bestia, tribune elect, Cethegus, two nephews of Sulla, and others. It was now his interest to be elected consul; he became a candidate, but was again unsuccessful. Cicero was elected with C. Antonius. Catiline now pushed on with greater vigor. The plot was matured; troops were levied, especially under C. Manlius, a centurion of Sulla, in the vicinity of Fæsulæ, in Etruria; arms were provided, the lists of proscription made out, and the day fixed for the assassination of the consuls and the general conflagration of the city. The watchfulness of Cicero saved himself and the republic. Fulvia, the mistress of one of the conspirators, was induced to communicate all the particulars; C. Antonius was made harmless by the promise of Macedonia as a province. Informed by Cicero, the senate intrusted the consuls with absolute power to save the republic from the threatening danger. At the following consular election Catiline was again rejected, and in the night of Nov. 6, 63, he declared in a secret meeting to his ringleaders that the time of action had arrived. Cicero, who knew their every movement, summoned the senate, and delivered his first great oration against Catiline, giving full and ample information of all the facts. Catiline was bold enough to be present and to attempt his justification; but his voice was drowned by the cries of "Enemy" and "Parricide" from the indignant senators, and he was left on his deserted bench a spectacle to the assembly. He left Rome in

the following night to join the camp of Manlius, leaving the management of affairs at the capital to Lentulus and Cethegus. Cicero now addressed the people in the forum, justifying his conduct; the senate declared Catiline and Manlius enemies of the republic, while legal evidence against the conspirators at Rome was furnished by the communications of the ambassadors of the Allobroges, who, being sent to Rome for the redress of grievances, were tempted by Lentulus to join the conspiracy, and to induce their nation to assist in it. Cicero, who received the information from their patron, persuaded them to feign an active participation, and to draw from Lentulus a list of the conspirators, as if by it to induce their countrymen to join in the enterprise. Lentulus and his friends fell into the snare. They were now brought before the senate, assembled in the temple of Concord (Dec. 4), and their guilt was proved. Having delivered his third oration before the people, Cicero on the next day again convoked the senate to deliberate on the punishment of the traitors. The debate was animated. Silanus, the consul elect, gave his opinion for the immediate death of all of them; this was opposed by Julius Cæsar, who was satisfied with their arrest and the confiscation of their estates, and who indeed has been suspected by historians of having been connected with the plot. Cicero gave no opinion, but painted in strong terms the dangers of the state. Cato, voting for death and for immediate efforts against the rebels in the field, made an appeal to the patriotism of the senate, and prevailed. A decree was passed, and Lentulus and his companions were strangled in the night in prison, in direct violation of Roman law. An army was sent against Catiline under the consul Antonius; but, unwilling to fight against his friend, he gave the command to his legate Petreius. They met near Fæsulæ. Catiline defended himself desperately, but in vain; when the battle was lost he threw himself into the midst of his enemies, and fell fighting.—Salust's masterly life of Catiline is our chief authority for his history, but is too obviously the work of a partisan to be implicitly trusted. Catiline was the leader of the ultra democratic party, and the supporters of the optimates who overthrew him may be suspected of having exaggerated his faults and misrepresented his designs.

CATINAT DE LA FAUCONNERIE, Nicolas de, a French general, born in Paris, Sept. 1, 1637, died Feb. 25, 1712. He entered the army as an ensign, and at the siege of Lille in 1667 so conducted himself as to attract the notice of Louis XIV. His subsequent exploits obtained for him in 1688 the rank of lieutenant general, and in 1693, after he had conquered the greatest part of Savoy, he received the marshal's staff. In 1701 he commanded the army in Italy against Prince Eugene; but failing to arrest the progress of the prince, Villeroy was appointed to his place. Catinat served

under him, and in attacking the intrenchments at Chiari he was repulsed and wounded. He commanded in Germany for a short time, and spent the rest of his life at his estate of St. Gratien, near St. Denis.

CATINEAU-LAROCHE, Pierre Marie Sébastien, a French lexicographer, born at Saint-Brieuc, March 25, 1772, died May 22, 1828. He studied at Poitiers, and in 1791 emigrated to St. Domingo, where he published at Port-au-Prince a journal, *L'ami de la paix et de l'union*. He gave such offence to the colonists by his anti-slavery sentiments that he was prosecuted, and would have been sentenced to death by the local tribunals but for the interference of the agent of the home government. He went to Cape Haytien (then called Cap Français), where he alone of 17 of his countrymen was saved from the massacre which broke out in that city. He then visited the United States and England, and on his return to Paris in 1797 established a printing office and composed several dictionaries. His printing office having been destroyed by fire, the government employed him, and in 1819 he was sent to study the climate and resources of Guiana. His notes on that country appeared in 1822.

CATLIN, George, an American artist, born at Wilkesbarre, Penn., in 1796, died in Jersey City, N. J., Dec. 23, 1872. He studied law in Connecticut, and practised there for two years. Afterward he devoted himself to painting in Philadelphia, without any previous instruction. Some Sioux Indians arriving on a delegation in the city, he was struck with their appearance, and determined to visit their homes. He started from St. Louis in 1832, in a steamer called the *Yellowstone*, being greatly assisted by Pierre Chouteau, one of the owners of the boat. After a passage of three months he reached the mouth of the *Yellowstone* river, where he was left. He visited during the next eight years about 48 tribes, numbering in the aggregate 400,000 souls, and collected much information concerning their habits and character. He returned to the east by the way of the Indian territory, Arkansas, and Florida, and after finishing his Indian portraits and scenes sailed for Europe in 1840. In 1841 he published in London "Illustrations of the Manners, Customs, and Condition of the North American Indians," containing 300 steel engravings (2 vols. 8vo); in 1844, a portfolio of hunting scenes in the west containing 25 plates; in 1848, notes of his eight years' travels in Europe with his collection of paintings; in 1864, a curious volume called "The Breath of Life, or Shut your Mouth," showing the hygienic importance of exclusive breathing through the nostrils. After several visits to and long residence in Europe, exhibiting and endeavoring to sell his Indian gallery, he returned to the United States in 1871, where he remained until his death.

CATMANDOO. See **KATMANDU**.

CATNIP, or *Catmint*, the leaves of a perennial herbaceous plant, *nepeta cataria*, of the family

labiate, which is very common in the fields throughout the United States, though supposed to have been introduced from Europe. The plant possesses medicinal virtues, so that it is

Catnip (*Nepeta cataria*).

recognized in the pharmacopœias, and is employed as a domestic remedy, but rarely in regular practice. The leaves, which alone are used, are aromatic and somewhat bitter and pungent to the taste, and of disagreeable odor; cats eat them with great relish. Catnip is administered in infusion. It acts as a tonic and excitant, and possibly as an antispasmodic and emmenagogue, being frequently given with reference to such supposed qualities.

CATO, a surname, signifying the Wise, first given to the Roman Marcus Porcius, known in history as Cato the Censor, and afterward borne by that family of the (plebeian) Porcian gens of which he was the first famous member. **L. Marcus Porcius**, afterward called **PRISCUS**, and surnamed **CATO** and **CENSORIUS**, a Roman statesman and patriot, born at Tusculum, probably in 234 B. C., died in Rome in 149. His father, the descendant of a family for many generations resident in Latium, died when he was very young, and left him a small estate at a considerable distance from his birthplace, in the territory of the Sabines. Here he spent his early youth in work upon his land, leading a simple life, and studying such subjects as he thought would best advance the career of patriotic service which he had already marked out for himself. When 17 years of age, in 217, he entered the Roman army, and served in the campaign of that year against Hannibal. In 214 he served at Capua, and in 209 he was with Fabius Maximus at Tarentum. During the short periods between his various terms of service he devoted his time to labor on his farm. Near this favorite resort a Roman patrician, Lucius Valerius Flaccus, had a large estate. Cato was constantly brought into contact with

him, and impressed the noble so favorably that the latter begged him to go to Rome with him, and under his patronage, as the custom was, to study law and oratory. Cato consented, and made his entry into the Roman political world with marked success, rapidly acquiring celebrity as a pleader and orator in the forum, and becoming a candidate for the quæstorship, an office which he attained in 205. In this capacity he accompanied Scipio Africanus to Sicily in 204, but went back to Rome before the return of his general, whom he accused to the senate of prodigality and mismanagement. This is the story given by some authorities, though Livy says the inhabitants of Locri were the complainants against Scipio, and does not mention Cato by name as having pleaded their cause. A commission of investigation was the result of the complaint, and Scipio was acquitted. Concerning the next few years of Cato's life we have slight details, but know that he was ædile in 199, and that in 198 he was made prætor, and received the province of Sardinia. Here he showed in his administration and mode of life the economy, simplicity, and impartial justice which distinguished his whole career. By the frugality of his habits, by his example in public, and his prompt punishment of venality and corrupt practices, he endeavored to combat the introduction of habits of luxury and extravagance from Greece, and to restore the old severity and strength of the Roman character. In 195 he was chosen consul, Lucius Valerius Flaccus, his former patron, being his colleague. It was then customary for one of the consuls to take the governorship of a distant portion of the Roman possessions, and Cato was assigned to that of Hither Spain, a province then in a state of revolt and great disorder. Here he showed remarkable ability as a military leader, suppressed the rebellion, compelled the Spanish cities to destroy the greater part of their fortifications, and restored affairs to their old condition. On his return to Rome in 194 he received the honor of a triumph. In the consulship of Manius Acilius Glabrio, which immediately followed his own, Cato accompanied that officer as legate in his campaign against Antiochus in Greece. Here, by a sudden and remarkably difficult march, he decided the principal battle of the war in favor of the Romans, and compelled the retreat of the enemy. Returning to Rome, he from this time abandoned military life, and resumed his place as a popular orator in the forum and the courts. In 184 he was made censor, again having his old friend Flaccus as his colleague. In the exercise of the censorship Cato gained the most enduring fame of his life. He was now in a position to powerfully oppose the growing corruption, luxury, and immorality at Rome, and to do more than ever toward restoring his old ideals of simplicity and severity of manners. He raised the taxes on luxuries of many kinds, degraded officers for the most trifling acts of levity as well as

for actual crimes, and bitterly persecuted those who opposed his acts. He improved the public works of the city, while introducing economy in the contracts, and stopped many abuses of the privileges of the citizens. Now, as during his whole life, he was warmly on the side of the plebeians, and opposed the nobles by every means given him either by his official or personal influence; so that his censorship was a constant struggle with the patricians, both in petty and important matters. In revenge they began against him several prosecutions, but he defended himself successfully in every case from their charges of maladministration. At the close of his censorship the people caused his statue to be erected and a commemorative inscription to be placed upon its pedestal. Cato now ceased to hold public office, except as a senator, but continued a remarkable activity in political affairs, never relaxing in his opposition to all forms of luxury, and attacking bitterly the vices of the nobles. He was employed in several important cases: in the prosecution of M. Matienus and Publius Furius Philus for maladministration in Spain (171); in the defence of the Rhodians from the charge of treachery toward Rome; and in others of equal moment. He took a leading part in the debates of the senate on all great questions, always favoring a policy intensely hostile to foreigners; his hostility toward all outside nationalities is shown in many familiar anecdotes. The patricians continued to manifest their hatred of him, and as late as 153, when he was 81 years old, Caius Cassius brought against him a serious accusation, the nature of which is not recorded, which compelled him to defend himself, with ultimate success. In 150 he began in the senate to urge an immediate declaration of war against Carthage (the third Punic war). With nine other deputies he was sent in that year to investigate the condition of the rival city, and was so impressed by its appearance of power and prosperity that he declared on his return that Rome could no longer permit so powerful an enemy to exist. His hatred of Carthage now became the absorbing passion of his life; he urged upon the people the importance of war, and never rose to speak or give his vote in the senate without adding to whatever else he said, no matter how foreign was the subject, *Ceterum censeo, Carthaginem esse delendam* ("I vote, moreover, that Carthage must be destroyed")—a sentiment more familiar in the form *Delenda est Carthago*, which Cato himself probably never used in formal debates. A part of the last year of his life was spent in aiding the prosecution of S. Sulpicius Galba for treachery; but this, though undoubtedly just, was unsuccessful. Soon after its conclusion Cato died, at the age of 85.—The character of Cato was bitter and severe; in private life, and especially in the treatment of inferiors and slaves, he exhibited the greatest harshness. His personal morality, tried by a modern standard, was in some respects not so

pure as it has been often represented by partial historians. After the death of his first wife Licinia he for a long time cohabited secretly with a female slave, and only married again, when nearly 80, on his son's discovery of his concealed course. But his honesty and patriotism were incorruptible at a time when those around him possessed little of either virtue. His energy was extraordinary, and his frugality, temperance, and simplicity were like those of the early patriots whom he endeavored to imitate. Though opposed to the influence of Greek literature, the principal source of refining education in his time, he possessed considerable culture and literary skill, and left an essay on agriculture (*De Re Rustica*), still extant, and the *Origines*, only fragments of which remain, besides less important works of which we also have a few portions. A collection of these was published in Leipsic, by Jordan, in 1860.—Cato left two sons; one, M. Porcius Cato Licinianus, afterward became a jurist of eminence; the other, M. Porcius Cato Salonianus, by his second wife Salonia, was born in his father's 80th year, and lived to become prætor. **II. Marcus Porcius**, surnamed **UTICENSIS** from the place of his death, a Roman statesman, philosopher, and general, great-grandson of the preceding, born in Rome in 95 B. C., died by his own hand at Utica in 46. Having lost his parents when he was very young, he was brought up and educated by his maternal uncle, Marcus Livius Drusus, and after the death of the latter by Sarpedon. As a boy and young man he was conspicuous for his gravity, firmness, and bravery when his anger was aroused. Going with Sarpedon upon one occasion to visit Sulla, and seeing the heads of several famous Romans, victims of the proscription, carried from the tyrant's house, it is said that young Cato asked why no one put an end to the despot; and on being told that none dare do so, he demanded a sword of Sarpedon, that he himself might free his country. Although he received an ample fortune from his father's estate, he imitated his ancestor the Censor in his extreme frugality and simplicity, opposing luxury, practising rigid economy, and strengthening his body by every form of difficult exercise and exposure. In the corrupt state of Rome in his time, he thus acquired a not undeserved popularity as the advocate of purer customs, and a reputation for moral rectitude such as had formerly distinguished the elder Cato. His first military experience was gained, in 72 B. C., as a volunteer under Gellius Publicola in the war with Spartacus, but he did nothing noteworthy in this earliest campaign. In 67 he became a candidate for the office of military tribune, and was elected in spite of his neglecting the ordinary corrupt means taken to gain the post. With his legion he was stationed in Macedonia, under the proprætor Marcus Rubrius. He was exceedingly popular with his command, and lived with the simplicity of a common soldier among

them, always sharing their hardships and difficulties. In his youth he had begun the study of philosophy, and had become a disciple of the Stoics. He continued the practice of their doctrines and the study of their works, and while stationed in Macedonia obtained a leave of absence that he might visit the philosopher Athenodorus Cordylion at Pergamus, whom he persuaded to go back with him when he returned to his legion. At this time Cato lost his brother, Servilius Cæpio, to whom he was warmly attached. Hearing of his having an attack of illness at a Thracian town, Cato hurried to meet him, but did not arrive in time to see him alive. He was overcome with grief, and, after celebrating Cæpio's funeral with great splendor, set sail for Rome on the ship bearing his brother's ashes. After several years of study in Rome, where Athenodorus was still his companion, he was elected quæstor in 65, and so distinguished his administration of the office by honesty, economy, and rigid justice, that he left it at the expiration of his term with his popularity greatly increased. A journey to Asia, as to the date of which authorities disagree, probably took place about this time. He visited King Deiotarus of Galatia, who received him with many marks of respect, but offered him presents, which so disgusted Cato that he pursued his journey the day after his arrival. Pompey, then in the East, also received him with respect, but without cordiality. In 63 Cato was elected tribune, consenting to be a candidate after having once refused, in order to defeat certain plans of Pompey, who was already plotting for the control of the state. In the same year, and in the consulship of Cicero, the Catilinarian conspiracy occurred. Cato voted for the death of the conspirators, and conferred on Cicero the title of *pater patriæ*. The great conflict for power between Cæsar and Pompey was now beginning. Cato, with the purest patriotism, not only opposed them both by every means in his power, but constantly warned the people of the danger of the state's falling under the control of any one man. His patriotism, however, was greater than his political ability, and he was easily outgeneralled by Cæsar, who in spite of his opposition carried almost every end he had in view. Cæsar, Pompey, and Crassus, to finally rid themselves of his interference with their plans, determined to send him against Ptolemy, king of Cyprus, although no possible cause for war existed, and to annex the island to the Roman possessions. Cato sent a message to Ptolemy telling him of the determination; and Ptolemy, rather than oppose Rome, poisoned himself, leaving Cato to take peaceful possession of his kingdom. This he did, returning to Rome in 56. In the next year he opposed the election of Pompey and Crassus to the consulship, but without success. He was exposed to great danger in the election riots, and was even wounded. In 55 also he was defeated in the election for prætor, in

great part because he refused to employ bribery to gain the office. During the next year he was again a candidate, and this time he was elected. As prætor he devoted himself to the suppression of the prevailing corruption, and made himself so unpopular by his severe prosecutions for bribery that he was even attacked in the streets by a mob, which he with difficulty succeeded in quieting. In 52 he supported the proposition to make Pompey sole consul; but repenting the next year of his share in giving him power, he himself became a candidate for the consulship, only to be defeated by two rivals, in the interest of Pompey and Cæsar. In 49, when the civil war began, and Cæsar approached the city with his army, Cato, after resisting by every means in his power the plans of the great leader, left Rome with the consuls, and went to Campania, where for some time he seemed to completely despair of the preservation of the state. He was soon, however, intrusted with the defence of Sicily, but abandoned it on the approach of Cæsar's army, and hurried to Pompey's camp at Dyrrhachium. He was left in charge of this during the battle of Pharsalia (48), but on Cæsar's victory he again withdrew his troops, and set sail with them for Coreyra, whence he continued his journey to Africa, to join Pompey. But he did not arrive until after Pompey's assassination, and took refuge in Cyrene, the inhabitants of which consented to admit him with his command. In 47 he again marched out of the city, and across the desert, to join Q. Metellus Scipio, to whom he yielded the command of his troops, advising him, however, not to risk an immediate engagement. Scipio persisted in doing so, and was defeated at Thapsus in April, 46. Utica alone, of all the African towns, held out against Cæsar; and even its inhabitants could not be persuaded by Cato longer to resist the conqueror. Cato had now no refuge; but he exhibited the greatest calmness. He made arrangements for the flight of his friends from the city, and for giving them an opportunity to make terms with Cæsar; but he himself remained behind, and resolved to die by his own hand rather than fall into the power of the enemy. He spent the last day of his life in pleasant intercourse with those about him, and at night retired early to his room, where he for a long time lay upon his bed reading Plato's "Phædo." Then, drawing his sword, he stabbed himself, and fell to the floor, the noise arousing his friends, who hastened to bandage his wound. But he tore the bandages away, and almost immediately expired. The people of Utica buried him with every honor, and erected a statue to his memory. Cæsar is said to have cried out, on hearing of his suicide, "Cato, I begrudge thee thy death, since thou hast begrudged me the glory of sparing thy life." As a man and a statesman Cato was pure, sincere, and conscientious to a degree most remarkable in his time; he had not the

harshness of his ancestor the Censor, yet he possessed unusual firmness. In politics, however, he had little skill, and his expedients to defeat his opponents, though never corrupt, were almost always clumsy and ill-advised. As a general he exhibited little ability.—He was twice married: first to Attilia, a daughter of Serranus, who bore him two children, but was divorced for adultery; second to Marcia, by whom he had three children. Singularly enough, he is recorded to have lent or yielded his second wife to his friend Quintus Hortensius, about 56 B. C., with her father's consent; taking her back after his friend's death, and living with her as before.

CATOOSA, a N. W. county of Georgia, bordering on Tennessee, and watered by affluents of the Tennessee river; area, 175 sq. m.; pop. in 1870, 4,409, of whom 616 were colored. It is traversed by the Western and Atlantic railroad. The surface is hilly and partly covered with forests. The chief productions in 1870 were 43,366 bushels of wheat, 90,855 of Indian corn, 19,909 of oats, 40,879 lbs. of butter, and 96 bales of cotton. There were 542 horses, 834 milch cows, 1,225 other cattle, 2,447 sheep, and 4,399 swine. Capital, Ringgold.

CATRON, John, an American jurist, born in Wythe co., Va., in 1778, died in Nashville, Tenn., May 30, 1865. He received a common school education, removed to Tennessee in 1812, studied law, and was admitted to the bar in 1815. In the New Orleans campaign he served in the army under Jackson, and was afterward elected state's attorney. He settled in Nashville in 1818, and was one of the supreme judges of Tennessee from 1824 to 1836. In 1837 President Jackson appointed him associate justice of the United States supreme court. He opposed secession, and was consequently obliged to leave the state. His decisions on the state bank are contained in "Yerger's Tennessee Reports," and his federal decisions in the later volumes of Peters, the 20 vols. of Howard, and the 2 vols. of Black.

CATS, Jakob, a Dutch statesman and poet, born at Brouwershaven in Zeeland, Nov. 10, 1577, died at Zorgvliet, near the Hague, Sept. 12, 1660. He studied law at Leyden, Orleans, and Paris, and on his return to his native land practised his profession for a while, and also published some successful poems. In 1627 he was ambassador to England, from 1636 to 1651 grand pensioner of Holland, and in 1652 again ambassador to England. He wrote a poem entitled "Country Life" (*Buitenleeven*), and numerous "Moral Emblems," fables, and songs. A new edition of his works, in 19 vols., appeared in Amsterdam in 1790-1800. A German translation of part of them was published at Hamburg in 1710-17. His "Emblems" have been translated into English. A monument was dedicated to him at Ghent in 1829.

CAT'S EYE, a semi-transparent variety of quartz penetrated by fibres of asbestos. It is commonly of a greenish gray color, though

sometimes yellow, red, or brown. When polished, it reflects a pearly light resembling the pupil in the eye of a cat.

CATSKILL, a village and the capital of Greene co., New York, situated on the W. side of the Hudson river, about 110 m. above New York; pop. in 1870, 3,791. There are several churches, a court house, jail, and some manufactories. It is the landing place for visitors to the Catskill mountains, and a ferry here crosses the Hudson, connecting with the railroad on the eastern bank.

CATSKILL MOUNTAINS, a group of the Appalachian chain, on the W. side of the Hudson river, lying mostly in Greene co., N. Y. Their E. base is 7 or 8 m. distant from the village of Catskill. These mountains range parallel with the river only for about 12 m., spurs from their N. and S. terminations turning respectively N. W. and W., and giving to the group a very different form from that of the parallel ranges of the Appalachians, as seen in Pennsylvania. It differs from these also in assuming more of the Alpine character of peaks considerably elevated above the general summits. It resembles them in the precipitous slopes toward the east, and the gentler declivities, which are lost in the high lands on the W. side. Its geological structure is almost a repetition of that of the main Alleghany ridge throughout Pennsylvania, the same formations succeeding in the same order from the E. base to the summit, and giving to it, even in a more marked degree than is there witnessed, the terraced outline due to the alternation of groups of strata, some of which are easily worn away, and others powerfully resist denuding forces. Along its E. base the strata of the old red sandstone formation are seen dipping in toward the central axis. These are succeeded by the gray slaty sandstones of hard texture, which make up the most precipitous slopes, except those of the highest summits, which are capped by the conglomerate of white quartz pebbles. This is the floor of the coal formation. Upon the Alleghany mountain it forms the highest knobs, which present their vertical fronts to the east and slope away to the west. The dip in this direction being there steeper than the declivity of the mountain, the coal beds find a place above the conglomerate; but upon the high peaks of the Catskills this rock lies too horizontally for higher strata to appear, and a descent to lower levels in a W. direction only brings to view again the same formations met with on the E. side. Thus, for want of 100 ft. perhaps of greater elevation, the Catskills miss the lowest coal beds. Even in the midst of the strata of the conglomerate its carboniferous character is seen by the black shales here and there pinched among its massive blocks, and by seams of anthracite of a few inches in thickness contorted into strange forms. These, before their real relations were understood, led to futile explorations to discover workable beds of coal in the hard sandstones of these sum-

mits. But it is now well understood that the Catskills can never claim regard for the value of their mineral productions. Their chief interest lies in the variety and beauty of their scenery. In a field of very limited area, easy of access and soon explored, they present a multitude of picturesque objects, which have long made them a favorite resort of artists and of those who find pleasure in the wild haunts of the mountains. From the village of Catskill a stage road of 12 m. leads to the "Mountain House," a conspicuous hotel, perched upon one of the terraces of Pine Orchard mountain, at an elevation of 2,500 ft. above the river. Here the traveller finds a cool and quiet retreat, and a convenient starting point for his explorations. A hotel has recently been erected on the summit of "Overlook" mountain, a few miles south of the Mountain house, at a height, it is asserted, of 3,800 ft. It is accessible from Rondout. From these hotels are obtained extensive views of the fine country around, of the Hudson river, visible with all the towns upon its banks from the Highlands to Albany, and of the mountains of Vermont, Massachusetts, and Connecticut. The most striking features of the Catskills are the cascades of the mountain streams, and the deep gorges or "cloves" through which these find their way to the lower lands. The highest summits are Round Top, High Peak, and Overlook, the elevation of which, according to barometrical measurements, is about 3,800 ft. The clove of the Catterskill, or Kaaterskill, which commences a mile W. of two small lakes, lies between these and Round Top, the latter being on the S. and the lakes on the N. side. High Peak is 6 m. distant from the head of the clove, and is reached by a foot path. The clove is a ravine of 5 m. in length. At its head the rivulet from the lakes meets another branch from the north, and their united waters flow with increasing swiftness to a point where the mountain divides like the cleft foot of a deer, leaving a deep hollow for the brook to tumble into. The descent of the first cascade is 180 ft., that of the second 80, and below these there is another fall of 40 ft. In the winter the upper fall becomes encased in a hollow column of blue ice, which reflects in the rays of the sun the brilliant colors of the prism. Below the falls the sides of the gorge rise in a succession of walls of rock to the height of 300 ft. or more. Other falls are met with by following the stream down toward the Hudson, till 2 m. above the village of Catskill the waters are discharged into the stream of this name. The Stony clove is 6 m. W. from the head of the Catterskill, in a portion of the group called the Shandaken mountains; it is only $1\frac{1}{2}$ m. long. The clove of the Plattekill is 5 m. S., beyond the Round Top and High Peak; its scenery possesses the same wild character as the Catterskill. Numerous side streams descend the steep mountain on its S. side from an altitude of 2,000 ft., leaping from ledge to ledge

till they mingle their waters with the Plattekill. Where the stream first falls into the clove it is said to descend in successive falls 1,000 ft. in a few hundred yards; and, as stated

Catterskill Falls.

by others, 2,500 in 2 m. The streams which flow down the E. slopes of the mountains soon find their way into the Hudson. On the W. side the drainage is into the Schohariekill, which runs northward and falls into the Mohawk 50 m. above its junction with the Hudson. The forest growth near the foot of the mountains is black and white oak, interspersed with hickory, chestnut, butternut, and several species of pine. Cedars and swamp ash are found in the swamps. The hard-wood growth of maple, beech, and birch is met with upon the better soils up the mountain sides, while hemlock, spruce, and the balsam fir occupy the more barren and rocky places. The valleys beyond the E. ridge contain forests of hemlock, with beech, birch, and wild cherry trees intermixed.

CATTARAUGUS, a S. W. county of New York, bordering on Pennsylvania; area about 1,250 sq. m.; pop. in 1870, 43,909. It is partly bounded N. by Cattaraugus creek. The surface is hilly, but there are few mountains of considerable altitude. The soil is rich and productive, yielding good crops of grain and affording excellent pasturage. The Alleghany river and the numerous creeks which flow through the county furnish motive power. Bog iron ore, peat, marl, manganese, and sulphur are found in different places; salt springs have been discovered, and petroleum springs exist in the E. part. Cattle and lumber are the principal exports, the transportation of which is greatly facilitated by the Erie railway, which traverses the county, and by the Genesee valley canal, which extends from Rochester to

Olean. The county is also traversed by the Bradford branch of the Erie and by the Atlantic and Great Western railroads. The chief productions in 1870 were 84,926 bushels of wheat, 160,602 of Indian corn, 783,387 of oats, 340,803 of potatoes, 144,919 tons of hay, 889,132 lbs. of cheese, 2,700,265 of butter, 110,063 of wool, 458,723 of maple sugar, and 35,121 of hops. There were 10,687 horses, 44,463 milch cows, 18,583 other cattle, 26,739 sheep, and 10,738 swine. There were 44 cheese factories, 15 tanneries, 8 currying establishments, 76 saw mills, 8 manufactories of agricultural implements, 11 of cheese boxes, 38 of carriages and wagons, 12 of furniture, 6 of iron castings, 18 of saddlery and harness, 7 of sashes, doors, and blinds, 14 of tin, copper, and sheet-iron ware, 2 of woollen goods, and 13 grist mills. Capital, Little Valley.

CATTARO (Slavic, *Kotor*), a town of Dalmatia, Austria, capital of a circle of its name, at the foot of the Montenegro mountains, at the S. E. extremity of the gulf of Cattaro, 337 m. S. E. of Trieste, and 43 m. N. W. of Scutari, Albania; lat. 42° 25' N., lon. 18° 46' E.; pop. about 3,000; of the circle, 36,000. The town was almost entirely destroyed by the earthquakes of 1563 and 1667. The streets are narrow, but the town is fortified by a castle on a cliff in the vicinity, and the port was made a naval depot in August, 1854. The harbor, although one of the best in the Adriatic, is little frequented by shipping; but it has a fair share in the commerce of Dalmatia. The trade of Cattaro is carried on by tribes: the Dobrotas, who trade with Trieste, the Perastros, with Venice, and several others. The principal articles of trade are wine, oil, figs, wool, silk, honey, wax, tallow, smoked meat, dried fish, butter, eggs, cheese, and charcoal. Outside the E. gate of the town is the bazaar, which is supplied with provisions by the Montenegrins. The principal buildings are the cathedral, a collegiate church, numerous other Roman Catholic churches, 2 Greek churches, 6 convents, a hospital, a gymnasium, and the residences of the governor and the bishop. The popular language is the Slavic dialect of Herzegovina, but Italian is the language of the educated classes, and used in the transaction of public affairs. The majority of the population of the town and circle consists of descendants of the Slavs who invaded the country in the 7th century; the rest of Italians, Bosnian Greeks, Serb Morlaks, Jews, Greeks, and gypsies. The Roman Catholic is the established religion, but about a quarter of the population profess the Greek faith.—In the middle ages Cattaro was the capital of a prosperous republic. In 1420 it submitted to the Venetians; in 1797 it was annexed to Austria; in 1805, by the treaty of Presburg, it was incorporated into the French kingdom of Italy, but did not pass into the possession of the French till 1807, having been occupied by the Russians in the interval. Finally, in 1814 it reverted again to Austria. In 1849 Cattaro organized an independent

government, but in January, 1850, was brought back under the sway of Austria. The circle of Cattaro was the seat of the Dalmatian insurrection of 1869.—The gulf of Cattaro, or *Bocche di Cattaro*, the Rhizonic gulf of antiquity, is a tortuous inlet of the Adriatic, 30 m. long, forming three basins connected by narrow straits, with an entrance from the sea only a mile and a half wide. It is surrounded by mountains, and is renowned for the beauty of its scenery. The fort of Castelnuovo defends the entrance.

CATTEGAT, or **Kattegat**, a large strait lying between Gothland in Sweden and Jutland, communicating with the North sea through the Skager Rack on the north, and with the Baltic through the Sound and the Great and Little Belts on the south; length 150 m.; breadth in the central part about 90 m. It is difficult of navigation, being not only shallow toward the shores and irregular in depth, but obstructed by several sand banks, one of which lies in the middle of the channel. The chief islands are Læsø, Anholt, and Samsø.

CATTERMOLLE, George, an English artist, born at Dickleburgh, Norfolk, in 1800, died in 1868. He is best known as a painter in water colors, although in his later years he worked chiefly in oil. Scenes from the feudal ages and the times of the English civil wars, which permitted him a variety of ornamentation and warm coloring, were his favorite themes. His most celebrated pictures are "Luther before the Diet of Spire," "Raleigh witnessing the Death of Essex," and the "Skirmish on the Bridge." He painted innumerable interiors of church and castle, together with designs illustrative of Scott's novels, Shakespeare's plays, the times of the English cavaliers, &c.

CATTI, or **Chatti**, an ancient German people, who according to Cæsar lived beyond the Ubii, whose seat was about Cologne, and were divided inland from the Cherusei by a wood which he calls Bacenis. Tacitus states that their country lay between the Rhine and Danube, extending from the Black Forest on the south to what were called the *Decumates Agri*, a tract of land which paid tithe to the Romans, and lay along the latter river, to the northward. If both statements be accurate, their territory must have been very extensive, including Hesse-Cassel on the north and Baden on the south. Tacitus describes their character, habits, and manner of life as far less barbarous, so far at least as regards their military tactics, than those of the other German tribes. Their force lay in their infantry, whom, besides their arms, they loaded with tools and provisions. They did not allow their young men to cut their hair or trim their beards until they had slain an enemy; and all youths of unusual strength and size were compelled to wear an iron ring until they should have gained the right to remove it by slaying a man in battle. They had no individual property in land or houses, but held everything in common. The Romans gained

many advantages over them under Drusus and under Germanicus, who destroyed Mattium, their chief town, but never wholly conquered them. They are last mentioned as existing toward the close of the 4th century, and afterward disappear among the Franks.

CATTLE, a class of domestic animals. In its primary sense, horses and asses are included in the term, as well as oxen, cows, sheep, goats, and perhaps swine. In England, beasts of the ox species are more precisely described as black cattle or neat cattle. In the United States, the term cattle is usually applied to horned animals alone. Like that of many other species of animals now domesticated, as the sheep, the dog, and our common barnyard poultry, the origin of the domestic ox cannot be traced distinctly to any type now existing in a state of nature. The distinctive characteristics of the common domestic cattle are smooth unwrinkled horns, growing sideways at their origin, and directed upward, or in some breeds downward and forward, with a semi-lunar curve. The forehead of the common ox is flat, longer than it is broad, and has the round horns placed at the two extremities of a projecting horizontal line, separating the front from the occiput; but the horns themselves differ so widely in the different breeds, which have been the result of thousands of years of domestication, that no specific character can be founded upon them. In color, like all highly cultivated domestic animals, they run through all hues and shades, from the plain blacks, whites, browns, reds, duns, grays, and blues, to every variety of piebald, mottled, spotted, flecked, or brindled; the colors being in some degree distinctive of the various select breeds. Thus the Devonshires run to self-colored red and light tan or dun; the Durhams to dark red piebald, with the white portions sometimes flecked or sanded, though this is rather an Ayrshire mark; the Alderneys to light red or yellow, and white; the Ayrshires to roan and piebald; and the small Scottish kyloes, or mountain oxen, to self-colored blacks, reds, and brindles. In Calabria there is still a large breed of snow-white cattle, formerly in great request for sacrificial purposes, which has descended unchanged from classic ages; and every traveller in Italy knows the large, gentle, gray and mouse-colored oxen of the Campagna. In Hungary there is a remarkable breed of gray or dark blue cattle, which have wide-spreading horns and coarse flesh, but fatten easily. In the East there exist many singular and distinct species, the most remarkable of which is perhaps the celebrated sacred or Brahman bull; a heavy, indolent, phlegmatic animal, with short reflected horns, large pendulous ears, and an enormous hump and dewlap of solid fatty matter. Its coat is smooth, and sleeker than even that of the common cattle, while its form approaches nearer to that of the bison. Besides this, they have the huge, morose, almost hairless buffalo, both wild and

half domesticated, with its great, erect, crescent-shaped horns, of 18 inches girth at the root, and 4 or 5 feet measure round the exterior curve; the little, hump-backed zebu; the yak, or grunting ox of Thibet, with a tail like that of a horse; and probably many other varieties, yet imperfectly known and undescribed.—It was formerly supposed that domestic cattle were descended from the wild European bison, *bos urus* (see Aurochs); but Cuvier has shown this idea to be erroneous, by pointing out permanent characteristic distinctions in the osseous structure, particularly in the formation of the skull and insertion of the horns. It appears that there has been generally overlooked by naturalists a race of perfectly wild cattle peculiar to the British isles, which, formerly known as the wild bull of the great Caledonian forest, seems to have ranged all the woody northern regions of the island. They were of medium size, compactly built, invariably of a dingy, cream-colored white, with jet-black horns and hoofs, and the upper half of the ears either black or dull red. They are represented as having formerly had manes; but that characteristic is lost. Within a few years three herds of these cattle were in existence: one in the chase of Chillingham castle, the property of the earl of Tankerville, in Northumberland; one in that of the duke of Hamilton, at Hamilton castle, in Scotland; and one at Drumlanrig, in Dumfriesshire. Lord Tankerville's herd were red-eared; those of the duke of Hamilton had the black ears which are considered characteristic of the pure Scottish race. Although kept in confinement within vast enclosed chases, these cattle were perfectly wild, tameless, and savage. They would hold no connection with other cattle, more than the red deer will with the fallow; they would not brook the approach of man, and evinced their original wild nature by the pertinacity with which the cows concealed their calves in deep brakes of fern or underwood, and resisted any approach to their lair. The structural characteristics of these cattle differ in no respect from those of the domestic ox; their invariable self-color is a certain evidence of the purity and antiquity of their breed, as it is a strong proof that they are not the descendants of tame animals, relapsed into a savage state; since such, as is the case with the South American herds, long retain their variegated hues, the tokens of domestication and servitude.—Of the cattle of continental Europe, the Polish or Ukraine oxen are large and strong, and fatten readily, the flesh being succulent and well flavored. The cows are shy, not fit for the dairy; color light gray, seldom black or white; oxen docile at work. On the plains of Jutland, Holstein, and Schleswig there is a fine breed with small, crooked horns, supposed to be allied to the Friesland and Holderness breed; colors various, mouse or fawn interspersed with white being most common. Red cows of this breed are seldom seen. The cows are good milkers in

moderate pastures. The oxen fatten well when grazed or stall-fed at the proper age, being fine in horn and bone, wide in loin, but not as hardy and strong for labor as the Hungarian breed. Nearer the Alps the cattle are stronger and more active. The largest are among the Swiss. The Fribourg race have very rich pastures in the vicinity of Gruyères. The cows most prized are large and wide in the flank, strong in the horn, short and strong in bone; they show a prominence about the root of the tail which would be considered a blemish by short-horn breeders. Their milk is rich in pasture, or when stall-fed on clover or lucern; the oxen are good workers, but heavy and slow, and fatten well. In the Jura there is a small, active mountain breed, that keep well on little food; they are of a light red color; oxen active and strong for their size, drawing by the horns. They are not profitable for stall-feeding, but good for mountain cottagers, as they climb like goats, feeding on the patches of pasture. The Norman breed give character to all the cattle in the north of France, except near the eastern frontier; they are light red, sometimes spotted with white; horns short, set well out, and turned up with a black tip; legs fine and slender; hips high; thighs thin; good milkers, with rich milk. They are usually fed on thin pastures, along roads and the balks which divide fields. In Normandy the pastures are better, and the

Alderney Bull.

cattle larger. The Alderneys or Jerseys, in France, are supposed to be a smaller variety of the Norman, with shorter horns and more deer-like forms. This breed is very docile, having been for generations accustomed to be tethered in fields, along the roads, or in yards. They are found in gentlemen's parks and pleasure grounds in England. A large number have been brought to the United States, but they are not considered so profitable as some other breeds. The Italian breed is most remarkable for immense length of horn. No pains is expended on this breed except in northern Italy, where the Parmesan cheese is made. The Italian cattle resemble the Swiss.—In England the breeding of cattle has been carried to the greatest perfection. Cæsar

states that the British in his time had great numbers of cattle, though of no great bulk or beauty. The island being divided into many petty sovereignties, cattle were the safest kind of property, as they could be driven away from danger. When more peaceful times returned, cattle were neglected for other productions, their size and number diminished, and not until within the last 150 years was any considerable effort made to improve them. The breeds in England are as various as the districts they inhabit, or the fancies of the breeders. A curious classification by the horns has obtained, having been found useful. The long-horns, originally from Lancashire, were much improved by Mr. Bakewell of Leicestershire, and are now found in the midland counties. The short-horns first appeared in Lincolnshire and the northern counties, but are now found in most parts of the island. The middle-horns, a valuable and beautiful breed, came from the north of Devon, the east of Sussex, Herefordshire, and Gloucestershire. The crumpled horn is found in Alderney, on the south coast, and in almost every park in small numbers. The hornless or polled cattle were first derived from Galloway, and now prevail in Suffolk and Norfolk. Which is the original breed of all has been disputed. It is held by some that the long-horns are of Irish extraction; that the short-horns were produced by the efforts of breeders; while the polled, though found in certain places from time immemorial, are supposed to be accidental; and that to the middle-horns must therefore be ascribed the honor of being the original breed. As the natives of Britain retired before invaders, they drove their cattle to the fastnesses of north Devon and Cornwall, the mountain regions of Wales, the wealds of Sussex; and there the cattle have been the same from that time until now, while on the eastern coast the cattle became a mongrel breed, conforming themselves to pasture and climate. Observation proves that the cattle in Devonshire, Sussex, Wales, and Scotland are essentially the same—middle-horned, not great milkers, active workers, easy to fatten; all showing traces of likeness to one breed, however changed by soil, climate, and time.—The earliest importation of cattle to America was made by Columbus in 1493; he brought a bull and several cows. Others were brought by succeeding Spanish settlers, of the Estremadura breed, and the vast pampas or plains of nearly the whole of Spanish America are now covered with immense herds of cattle descended from these. They are of large size, long-legged, as various in color as other breeds, and their distinguishing characteristic is their long and widely extended horns. Herds numbering many thousands roam at will in a wild state, under the care of a race of herdsmen called gauchos. (See GAUCHOS.) Every year the calves are caught, branded with the marks of the respective owners of the herds, and turned loose again. The mode of captur-

ing the cattle is by the lasso or the bolas, and when thus caught the wildest are soon reduced to submission. Those which are retained for dairy and other domestic purposes are kept in

Long-Horned Brazilian Ox.

staked enclosures, capable of holding thousands of head, and called *estancias*. The lactiferous qualities of the cows of this breed are far below those of European and American domesticated cattle, but the milk is exceedingly rich, and particularly adapted to cheese making. Colombia, Venezuela, Brazil, and the Argentine Republic are the great cattle-raising countries of South America. In Ecuador, Chili, Peru, and Bolivia the cattle are domesticated. For many years cattle raising was almost the only pursuit of Californians, and it is still the calling of a large number of the people. In California, and also in Texas, the cattle of 20 or 50 owners roam over the pastures of all, every animal bearing on the left hip the brand, or "iron" as it is termed, of its owner; and the keepers or herders of these cattle are as expert as the South Americans with the lasso. (See *BOLAS*, and *LIASSO*.)—The Portuguese took cattle to Newfoundland about 1553, but no trace of them now exists. Norman cattle were brought to Canada about 1600. In 1611 Sir Thomas Gates brought from Devonshire and Hertfordshire 100 head to Jamestown. In 1624 Francis Winslow brought three heifers and a bull to Massachusetts. At this period no fixed breeds, as such, were known in England. In the United States there is now a class of native cattle, arising from a mixture of various breeds imported by the early settlers, who, for the want of barns, and from habits established in a milder climate, allowed their cattle to suffer severely; many perished, the survivors degenerating in size and quality. As agriculture advanced and settlers became more prosperous, the cattle were improved; and there are to be found in different districts native cattle varying with the richness of soil, salubrity of climate, and care of breeders. The English breeds, gaining celebrity, attracted the attention of enterprising breeders here, who com-

menced importing the Durhams, Devons, Ayrshires, Herefords, and Alderneys, with a few Galloways and some long-horns, and occasionally a few Scotch cattle. These cattle, imported at great cost, and not inured to our climate and rough treatment, prospered only in the best situations, and for a long period attracted little attention from ordinary farmers. At present there are many places where the pure breeds are propagated, each having its advocates; while farmers who make money from milk, butter, and cheese, stoutly maintain the value of native cattle and their crosses with the best breeds. There are, however, few neighborhoods where traces of imported blood may not be found; indeed, the high prices for cattle and their products which have prevailed since 1850 have done much to stimulate breeders to improvement. The short-horn or Durham is becoming the favorite breed in the West. The model of this breed forms a solid rectangle, or parallelopiped, when the head and legs are re-

Short-Horn Durham Bull.

moved, leaving no unfilled space and much solid meat with little offal. Of this breed "Allen's American Short-Horn Herd Book" says: "They are, as a race, good milkers, remarkable in the richness of its quality, and the quantity is frequently surprising. For beef, they are unrivalled. Their capacity to accumulate flesh is enormous, and they feed with a kindliness and thrift never witnessed in our native breeds. In milk, instances have been frequent in which they have given 24 to 36 quarts a day, on grass pasture only, for weeks together; yielding 10 to 15 lbs. of butter per week. Cows have slaughtered 1,200 to 1,500 lbs. neat weight, with extraordinary proof; and bullocks upward of 2,500 lbs." The short-horn crosses with native stock are much prized, forming good milkers, easy keepers, and profitable animals for beef, and in the hands of ordinary farmers prove better than the pure breed of short-horns. About 1835 some Ayrshires were imported, and this breed has ever since borne in the United States a high character for milk, yoke, and

shambles. The Hereford breed does not seem to find general favor. A large herd of Alderneys, of the most symmetrical proportions for that breed, was imported some years since, and

Dolly Ayrshire Cow.

seem admirably adapted to light thin pastures. Though their milk is very rich, the quantity is small. They are poor for beef, and not famous as workers; some breeders in the eastern states, however, believe them to be very profitable for butter and cheese. The long-horns have been sparingly imported, and do not find favor. The Sussex are better liked, though few have been introduced, while their supposed congeners, the Devons, are held by many intelligent men to be superior to the Durhams for all the southern and most of the older states. Being an original breed, and without cross or admixture of blood, they have sustained a superior capability of improvement among the best breeders wherever they have been bred with care. The hide is soft and mellow, indicating an aptitude to fatten, the bones small, and in color, grace, and elegance of carriage, they possess a superiority over all other British cattle. The little Kerry cow of Ireland, termed the "poor man's cow,"

Kerry Bull.

has been recommended for poorer lands in mountainous regions, but as yet no steps have been taken to introduce her there.—Cattle have many complaints, yet generally they are exempt

from great mortality. Sometimes, however, an epidemic prevails widely among them for a time, carrying off great numbers. (See MURRAIN, and PLEURO-PNEUMONIA.) Occasionally the "milk sickness" appears in some districts W. of the Alleghanies, when the animal sickens and dies, giving the peculiar disease to all who partake of her milk or flesh. It is supposed to originate from the *rhus toxicodendron* or poison ivy. The remedy is feeding large quantities of Indian corn. The horn distemper and hoof ail sometimes prevail extensively, and about cities where the cattle are closely confined and badly fed, they become ulcerated and otherwise diseased. No class of animals are so free from maladies as neat cattle when well treated. Good pasturage, good hay, grain, roots, and water, and airy stables, with sufficient exercise, are necessary to maintain good health in cattle or to improve their condition. Variety of food is essential, and the feeding of roots in winter is particularly necessary. The practice of soiling in summer has found favor with those who have fairly tried it. The cattle are kept in cool, clean stables, and green rye, oats, corn sown broadcast, lucern, clover, and sorghum are cut and carried to them. (See CALF, and OX.)

CATTYWAR, or **Kattywar**, a peninsula in N. W. India, forming a considerable part of the province of Guzerat, or the Guicowar's dominions, bounded N. by the gulf and run of Cutch, N. E. by the British provinces of Rajpootana and Malwa, E. by the gulf of Cambay, and S. and W. by the Arabian sea. It lies between lat. $20^{\circ} 42'$ and $23^{\circ} 10' N.$, and lon. $69^{\circ} 5'$ and $72^{\circ} 14' E.$ The principal product is cotton. The grains chiefly cultivated are wheat, maize, and millet. The sugar cane is grown extensively, but is only made to produce molasses or *goor*. The Cattywar horse, once celebrated, has deteriorated. A breed of kine called *desam* and buffaloes are much valued. The soil is sandy and not fertile, but numerous streams and wells afford ample means of irrigation, all the rivers taking their rise in the central part of the province. Toward the south some of the hills are over 1,000 ft. high. Deep ravines and caverns are very numerous, and afford safe retreats against attack. A locality of wooded hills called the Gir is haunted by wild animals of the most ferocious kind, and noted for its deadly climate. The ravages of migratory rats produced such a terrible famine in 1814, that this year has since been called the rat year. (See GUZERAT.)

CATULLUS, **Caius Valerius**, a Roman poet, born in Verona in 87 B. C., died in or after 47. He belonged to a noble family, and his father was a *hospes* of Julius Cæsar, a tie sacred among the Romans. The son went to Rome, and became acquainted with Cornelius Nepos, Cicero, and other notable men; but possessing a moderate fortune, he did not enter upon public life, living in retirement at Rome and at his villa near Tibur. He is the earliest Latin lyric poet of any importance. We have 116 poems of Ca-

tullus, mostly short and without arrangement by subjects; a few are strictly lyrical, some are elegiac, one is heroic, but most are epigrammatic. From his imitation of the Greeks, Catullus was called *doctus*, but he possessed much originality; there is in his style a certain air of antiquity which the Romans greatly admired. The text of Catullus seems to have been early corrupted; all MSS. are derived from one source, and that an imperfect one. There are several poems of unknown authorship which are ascribed to Catullus; the elder Pliny mentions *De Incantamentis*; and *Ciris* and *Peregrillum Veneris* have been attributed to him, but the latter is now generally believed to have been written by Florus in the 2d century. In his epigrammatic poems the Roman spirit prevails, and in the elegiac the Greek. Most of his epigrams are pleasant light impromptus, full of irony and satire, of various forms and on a great variety of subjects; they contain many obscure passages and some allusions offensive to modern ears; they are composed in 13 different metres. The elegies are imitations of the Greek, especially of Callimachus and Sappho; they exhibit, however, great vigor of language, and less frivolity than his epigrams. A good edition of his works is that of Sillig (Göttingen, 1823); of more recent editions, one of the best is that of R. Ellis (1866). They have been translated into English by G. Lamb (1821), T. Martin (1861), J. Cranstoun (1867), and R. Ellis (1871).

CATULUS, the name of a Roman family of the plebeian gens Lutatia. **I. Caius Lutatius**, consul with Aulus Postumius Albinus in 242 B. C. On March 10, 241, he won a great and decisive naval victory over the Carthaginians, near the island of Ægusa. This battle put an end to the first Punic war, compelling Hamilcar to agree to most disadvantageous terms of peace. Catulus claimed and obtained a triumph, which was celebrated on Oct. 4. **II. Quintus Lutatius**, consul with Caius Marius in 102 B. C., died in 87. He entered upon his term of office just as a powerful body of northern tribes were preparing to descend upon Italy. Marius, with one portion of the army, was sent to oppose the Teutons, who were about to enter the country from Gaul in the neighborhood of the modern Nice; while Catulus undertook to oppose the Cimbri who were advancing from the Tyrol. He took up a position not far from the source of the Adige, and awaited their attack; but the enemy, in spite of his opportunities for defence, assailed him with such violence as to drive his army across the Po. Marius, who had meanwhile defeated the Teutons at the battle of Aquæ Sextiæ, and returned to Rome, now hastened to aid his colleague. His army and that of Catulus recrossed the Po and defeated the Cimbri at Vercellæ (Vercelli). The accounts of this battle, which was fought in July, 101, are rendered most obscure by the jealousy of partisan writers, some of whom give all the

glory to Marius, others to Catulus. It undoubtedly belonged to the former, if the accounts of the public feeling at Rome are to be trusted. In the civil war Catulus espoused the cause of Sulla, and was among those named in the lists of the proscription of 87 B. C. He preferred suicide to falling by the hands of his enemies, and killed himself by suffocation with the fumes of charcoal. **III. Quintus Lutatius**, son of the preceding, died in 60 B. C. He earned distinction by his honesty and patriotism, and was made consul in 78. He quelled a revolution which his colleague Lepidus excited after the death of Sulla. In 65 he was made censor. Catulus is highly praised by Cicero, whom he earnestly aided in the suppression of Catiline's conspiracy.

CATURZE, Jean, a French heretic, born at Limoux, died at the stake at Toulouse in June, 1532. He was a popular professor of law and other sciences, and was driven in 1531 from his native place on account of his heretical doctrines. The next year he was arrested in Toulouse and sentenced to be burned. The accounts are conflicting in regard to the precise facts, but it is certain that he was put to death as a heretic, and that his friends, and especially his pupils, regarded him as a martyr. Étienne Volet, who defended him in a public speech (Oct. 9, 1532), was himself eventually doomed to a martyr's death in Paris, Aug. 3, 1546. Rabelais alludes to the tragic end of Caturze in his *Pantagruel*.

CAUCA, a river of South America, rising in that part of the Colombian Andes called Paramo de Guánacos, in the United States of Colombia, lat. 2° N., lon. 76° 30' W. On descending from the mountains, its course is W. until about 15 m. W. of the town of Popayan, where it bends N., and flows with the impetuosity of a mountain stream almost parallel to the Magdalena, which river it enters at the town of Nechi, lat. 9° N. The whole course of the Cauca is about 600 m.; it is navigable only for small craft, and not above Cali, which, with Toro, Buga, Antioquia, and Nechi, are the principal towns upon its banks. The valley which it waters, lying between the W. and central Cordilleras of the Andes, is one of the most fertile in the western continent.

CAUCA, a state of the United States of Colombia, bounded N. by the Caribbean sea, E. by Cundinamarca, S. by Ecuador, and W. by the Pacific ocean; area, 260,000 sq. m.; pop. about 435,000. It is traversed by the river of the same name, and is one of the richest, most fertile, and most populous districts in South America. It consists of two plateaus of different elevation, and consequently of different temperature; the land is well cultivated, and produces the various cereals, coffee, sugar, tobacco, cotton, and cocoa, the last being especially abundant; and vast and rich pastures afford nourishment for innumerable herds of cattle and mules. The fields and farmhouses present the appearance of wealth and comfort. Gold

has been found in the upper part of the valley. Capital, Popayan.

CAUCASIA. See CAUCASUS.

CAUCASIAN RACE. See ETHNOLOGY.

CAUCASUS, a general name given to the region and the chain of mountains therein which stretch between the Black and Caspian seas, the mountains forming part of the boundary between Europe and Asia. The region traversed by the range diagonally from N. W. to S. E. forms the Russian lieutenancy of Caucasia. It lies between lat. $38^{\circ} 50'$ and $46^{\circ} 30' N.$, and lon. 37° and $50^{\circ} 30' E.$ Its longest diameter, N. W. to S. E., is about 800 m.; area about 170,000 sq. m.; pop. in 1867, 4,661,824. It is divided into the following governments and districts: Kuban, Stavropol, Terek, Daghestan, Zakatal, Tiflis, Kutais, Sukhum, Tchernomore (Black Sea), Elizabethpol, Baku, and Erivan. The first five, which lie in Europe, are called Ciscaucasia, and embrace, among others, the territories of the Kuban and Nagai Cossacks, the Kabarda, the Tchetchna, and the land of the Lesghians; the last seven lie in Asia, are designated as Transcaucasia, and include Circassia, Abkhasia, Mingrelia, Imerethia, Georgia, Russian Armenia, and Shirvan. An outline of the central part of the country would represent a system of round-topped mountains, exhibiting few of those peaks which distinguish the Alpine and other chains, their sides seamed with deep but fertile valleys, descending to the steppes or plains which stretch N. into the main country of the Cossacks, and S. E. toward Persia. The Caucasus range commences in a line of cliffs fronting on the Caspian sea, at the peninsula of Apsheron, whence the main chain stretches in a N. W. direction to the shores of the Black sea, a distance of 700 m., and terminates in the promontory where the sea of Azov unites with the Black sea, near the Russian fortress of Anapa. From the main chain other ranges branch N. and S., giving the hill country a width of from 65 to 150 m. The principal subsidiary chains are on the north. The principal summits are Mount Elbruz or Elburz, on the N. E. confines of Abkhasia, 18,514 ft. high; Kasbek, W. of the road from Mozdok to Tiflis, about 16,500 ft. (like the preceding, first ascended by three young English tourists, Freshfield, Tucker, and Moore, in July, 1868); and Syrkhbarsom, between Elbruz and Kasbek, about 15,600 ft. The passage of these mountains is effected through defiles, some of which have a historic celebrity. Such are the Caucasian, now called the Darial pass or pass of Vladikavkar; the Albanian or Sarmatic pass in Daghestan; and the Iberian, now called the Sharapan pass, in Imerethia. Only one road is practicable for carriages, that from Mozdok to Tiflis, by the Darial pass and the valley of the Terek. The mountains of the Caucasus are either flat or round-topped. The geological structure of the greater portion is of secondary formation, interspersed with volcanic rocks. The

summits and central ridge are granitic; on each side the granite has schistose mountains joining it, and these are succeeded by calcareous hills whose bases are covered by sandy downs. The mountains are more abrupt on their north face; southward they descend by a succession of terraces. Snow rests on summits over 11,000 ft. in altitude throughout the year. The glaciers are but of limited extent, and no active volcanoes are known. Earthquakes occur. There are few lakes. Twelve watersheds or channels are counted, six on the N. slope, and six on the S. The principal rivers on the northward are the Kuma and the Terek, flowing E. to the Caspian, and the Kuban, W. to the Black sea. On the S. the Kur (the Cyrus of the ancients) flows E., and the Rion (Phasis) W.—The country of the Caucasus possesses every variety of climate, from the arid heats of the valley to the cold of perpetual snow. Vegetation in the habitable districts is luxuriant. Forests of the finest timber clothe the hills almost to the snow line. Grain will grow at an elevation of 7,000 ft. In the central belt the ordinary species of fruits produce well. Dates, pomegranates, and figs ripen in the valleys. Rice, flax, tobacco, and indigo are sure crops. The culture of sugar cane, silk, and cotton has been introduced into some localities. The tea plant has been recently introduced at Sukhum Kaleh, on the Black sea. Among the productions peculiar to the Caucasus are a species of cochineal insect; a hard-wood tree called locally *utchelia*, with wood of a rose color, suitable for cabinet work; also the Caucasian goat, celebrated for the value of its hair; and a wild animal of the feline species, called by the natives *chaus*. The horses of the Caucasus bear a high character for endurance and docility. Wild cattle are found in the forests. Wolves, bears, jackals, lynxes, and the minor fur-bearing animals, are numerous. The wool of the ordinary breeds of sheep is long and fine. Almost every species of birds known to the latitude are found here. Few minerals have been discovered; gold appears to be totally wanting; iron, copper, saltpetre, and lead are found, the last in considerable quantity.—The Caucasians proper, including Circassians, Mingrelians, Abkhasians, Ossetes, Tchetchentzes, Lesghians, Grusians, and many other tribes, of Indo-European race, are generally a bold and resolute people, hunters, robbers, and guerillas from choice, shepherds and agriculturists only from necessity. Although hospitable, they are jealous and revengeful. They live in villages built of stone. Formerly their youth of both sexes were raised for sale in the slave markets of Constantinople; but that traffic has been suppressed. Their political organization was formerly a loose sort of republicanism, under the nominal presidency of a hereditary prince; but the rule of Russia is now firmly established over them. Literature they have none. Their religion is an offshoot of Mohammedanism, corrupted from many sources.—An-

cient history makes frequent mention of the Caucasus. Here Prometheus was chained. Deucalion, Pyrrha, and the Argonauts, Sesostri and the Egyptians, the Scythians, Mithridates, Pompey, and Trajan are associated with its history. The Arabs, Tartars, and Turkomans successively ravaged the country to its base. Russia and Persia then struggled for its possession, until in 1813 the Russians, after having occupied Mingrelia, Imerethia, and Georgia, became nominally possessed of the S. E. parts of the mountains by treaty. A desultory warfare of several years ended by the mountaineers being reduced to a condition nearly approaching subjection. But in 1823 a new movement sprung up in the mountains. Mohammed, the mollah, commenced against the Russians a campaign in Daghestan. A chieftain named Kasi-Mollah was soon recognized as the head of the movement, having for his aid a young man named Shamyl. In 1829 the N. W. portion of the mountains fell into the hands of the Russians by the treaty of Adrianople, but the Circassians soon rose in arms against them. The various tribes now united in resistance, but the Lesghians and Tchetchentzes bore the brunt of the struggle. Kasi kept up a resistance to the Russian power till 1831, when he was shut up in Himry. The Russians stormed the place, and the chief was slain. Hamsad Bey next took the field, but his career was cut short by assassination. The mollah Mohammed being now dead, Shamyl was elected his successor, and carried on the war with varying success. In 1837 Shamyl inflicted a severe defeat on the Russians under Gen. Ivelitch. During 1838 the Caucasians were employed in preparing themselves for future resistance. The passes of the mountains were fortified, and the strong position of Akulgo was put in readiness to stand a siege. In 1839 the Russians, under Gen. Grabbe, entered the territory, defeated the Caucasians, and drove them back upon Akulgo, which was finally taken, Aug. 22, after a blockade of 72 days, and three days' hand-to-hand fighting. The Caucasians once more nominally succumbed to the Russian power, but in March, 1840, they again revolted. Having found European tactics ineffective in the previous campaign, they fell back on their old system of guerilla warfare. Gen. Grabbe again attempted to penetrate into the mountains, but was compelled to retreat. The next attempt was made in 1845 by Prince Vorontzoff, governor general of the Russian Caucasian provinces. He penetrated to Dargo, which he found in flames. The campaign being over, a new plan of action was introduced against the mountaineers. Hitherto the tactics had been to bring them to pitched battle, with the hope of breaking their strength at a single blow. Now the plan was to send detached columns against isolated spots, and wherever a footing was obtained to erect a fort on it. Notwithstanding this, the Caucasians continued to

carry on offensive operations. In 1846 they swept the line of Russian forts, and returned to their mountains laden with plunder. In 1848 and 1850 they made similar expeditions, and in 1853 they took from the Russians several guns, and drove them back from eight leagues of territory. During the Crimean war there was a pause in the operations in the Caucasus. In 1856 the Russians opened a warfare, which they continued till April, 1859, when the capture of the stronghold of Veden virtually decided the contest. Shamyl retreated to his last stronghold, the mountain fort of Ghunib, near the Caspian sea. Here, on Sept. 6, he was defeated after a desperate conflict and forced to surrender, and was carried a prisoner to Moscow and St. Petersburg, but treated with the utmost consideration. The Caucasus had in many parts become desolate. The bulk of surviving Circassians emigrated to Turkey. (See SHAMYL.)

CAUCASUS, Indian. See HINDOO-KOOSH.

CAUCHON, Joseph, a Canadian statesman and journalist, born in Quebec in 1820. He studied law, but, though admitted to the bar, never practised. In 1844 he was elected to the legislature for the county of Montmorency, and has been a member of parliament since that time. In 1851 he was offered a seat in the cabinet, but declined. The next year he attempted to form a French Canadian conservative opposition, but without success. In 1855 he became a member of the administration as commissioner of crown lands, and under his name a report was published attacking the monopoly of the Hudson Bay company. From 1867 to 1872 he was speaker of the senate. He afterward resigned his place in the administration and went into opposition. In 1842 he founded the "Quebec Journal," and has conducted it ever since.

CAUCHY, Augustin Louis, a French mathematician, born in Paris, Aug. 21, 1789, died May 23, 1857. Admitted in 1805 to the polytechnic school, he distinguished himself by the solution of difficult problems. He was admitted to the academy in 1816, and about the same time appointed professor of mechanics in the polytechnic school. The journals of the academy and several European mathematical journals contain numerous memoirs from his pen. His attachment to Bourbon legitimacy prevented him from taking the oath of allegiance, by which alone he could retain the public offices which he held in 1830, or accept those offered him on subsequent occasions. In 1848, however, he was appointed to the chair of mathematical astronomy which was then instituted at the Paris university; but refusing to take the oath of allegiance, he relinquished his post in June, 1852. He made contributions to almost every branch of mathematics, but his reputation rests chiefly on his residual and imaginary calculus. Among his numerous works are: *Cours d'analyse* (Paris, 1821); *Leçons sur les applications du calcul infinitésimal à la géométrie* (2 vols., 1826-'8); *Exer-*

cices mathématiques (1826-9); *Sur l'application du calcul de résidus* (1827); *Leçons sur le calcul différentiel* (1829); *Mémoire sur la dispersion de la lumière* (1836); and *Exercices d'analyse et de physique mathématique* (3 vols., 1839). His politico-religious writings testify both to his faith in legitimacy in politics, and in Roman Catholicism in religion. One of his most characteristic works of the kind is his poem *Charles V. en Espagne* (1834).

CAUCUS, a word of American origin, employed in the United States to designate a part of the political machinery of the country, which, though resting merely on usage, forms a marked feature of the American political system. The oldest written use of this word is probably in the following passage in John Adams's diary, dated Boston, February, 1763: "This day learned that the caucus club meets at certain times in the garret of Tom Dawes, the adjutant of the Boston regiment. He has a large house, and he has a movable partition in his garret which he takes down, and the whole club meets in one room. There they smoke tobacco till you cannot see from one end of the garret to the other. There they drink flip, I suppose, and there they choose a moderator who puts questions to the vote regularly, and selectmen, overseers, collectors, wardens, fire wards, and representatives are regularly chosen before they are chosen by the town. They send committees to wait on the merchants' club, and to propose and join in the choice of men and measures. Capt. Cunningham says they have often selected him to go to those caucuses," &c. Gordon, in his "History of the American Revolution," under date of 1775, traces this practice to a much earlier date: "More than 50 years ago Mr. Samuel Adams's father and 20 others, one or two from the north end of the town where all the ship business is carried on, used to meet, make a caucus, and lay their plans for introducing certain persons into places of trust and power. When they had settled it, they reported and used each their particular influence with his own circle. He and his friends would furnish themselves with ballots, including the names of the parties fixed upon, which they distributed on the days of election. By acting in concert, together with a careful and extensive distribution of ballots, they generally carried the elections to their own mind. In like manner it was that Mr. S. Adams first became a representative for Boston." It has been conjectured that caucus is a corruption of calkers. Very possibly the caucus club which met in Tom Dawes's garret was originally a mechanics' club, called from the leading trade in it the calkers' club, which name, with a variation, it still retained after it had passed into the hands of politicians. Mr. J. H. Trumbull derives the term from an Algonquin word meaning to speak, encourage, instigate. The singular of the Indian noun is said to have been *kaw-kaw-wus*, plural *kaw-kaw-wus-sough*, "counsellors," which the Vir-

ginians changed into *cocharouse*, designating a petty chieftain, and that thence come caucusers and caucus.—The change of government consequent on the revolution led, in the northern states especially, to a great increase in the number of elective offices, while the prevailing idea of the impropriety of self-nominations and of a personal canvass for votes made some nominating and canvassing machinery necessary. Meetings held for this purpose received the name of caucuses. Each party held in each election district its own caucus to nominate candidates. Public notice of the time and place was given, and every voter of the party was at liberty to attend. A moderator and clerk being chosen, a nomination list was opened. Each person present nominated whom he pleased. Several copies of the list were made and distributed through the meeting, each person placing a mark against the candidate whom he proposed, and the candidate having the highest number of marks was declared the nominee. This method, however, was evidently inapplicable where the constituency was large or the district extensive. Hence the substitution of a representative caucus, delegates being appointed at meetings like that above described, held in case of cities and large towns in the wards, and in country districts in the townships. These elective caucuses commonly took to themselves the name of nominating conventions, and their introduction marks a third era in the development of the caucus system. A considerable period, however, elapsed before this convention system was applied to state or presidential nominations. The members of the state legislatures in the one case and of congress in the other, those of each party holding their own separate caucus, took upon themselves to make these nominations. At first these legislative and congressional caucuses were held privately. Afterward, however, they came to be formally and avowedly held. Committees were appointed to look after the elections, and besides a state committee the legislative caucuses assumed the power of nominating the chairmen of the local county and district conventions. At length it began to be objected that in these legislative caucuses only those districts in which the party was in the majority were represented, and this and other causes led, between 1820 and 1830, to the substitution in New York and Pennsylvania of state conventions in their place; a custom since universally imitated. Congressional caucuses about the same time fell into disfavor. That held in 1823 to nominate a successor to Monroe was but slenderly attended; and its nomination was extensively disregarded, so that Mr. Crawford, its nominee, was behind both Jackson and Adams in the popular vote. At the presidential election of 1828 Adams became the candidate of one party and Jackson of the other, without any formal nomination. The congressional caucus system being exploded, the Jackson or democratic party held in 1832 a national

nominating convention, each state being entitled to the same number of votes as in the presidential election; and similar conventions of that party have been held to nominate candidates for each succeeding presidential term. The opposition, then known as whigs, adopted the same policy in 1837, and since that period all nominations for the presidency, by whatever party or fragment of party, have been made by a similar agency. The power of assembling these bodies usually rests with a committee appointed by the previous convention. Besides judging the qualifications of their own members, and nominating candidates, they assume the power of drawing up party creeds or platforms, as they are called, and of determining, in case of new and important questions, what position the party shall take.

CAUDEBEC, a town of France, in the department of Seine-Inférieure, on the Seine, 26 m. E. of Havre; pop. in 1866, 9,184. The principal

Caudebec.

edifice is the parish church, a celebrated Gothic building in the florid style of the 15th century, with a spire 330 ft. high. It has manufactures of cotton and wool, and a brisk trade. It was formerly the capital of the Pays de Caux, but declined in consequence of the emigration of the Protestants after the revocation of the edict of Nantes. It was taken by the English in 1419, and by the Protestants in 1562. In 1592 it was besieged and taken by a Spanish force under Alexander Farnese, who received a wound beneath its walls which proved fatal.

CAUDINE FORKS (*Furcæ Caudinæ*, rarely *Furcæ Caudinæ* or *Caudinæ Fauces*), two narrow passes through the mountains of ancient Samnium, affording access from opposite sides to an enclosed plain that lay between them. Most authorities consider them to have been identical with the valley now called the Val d'Arpaja, by which passed the road from Capua to Beneventum; but this does not at all accord

with the description of Livy, and in recent works the most weighty objections have been made to the received theory of their position, several writers contending that the valley of the little river Isclero, a short distance away, is the locality described by the Roman historians. The Caudine Forks are famous for the great disaster which here overtook the Roman army under Veturius and Postumius in 321 B. C., during the Samnite war. The consuls, misled by a false report that the Samnites were besieging Luceria, an important town of northern Apulia, hurriedly broke up their camp near Calatia, and prepared to hasten across Samnium to the rescue. The nearest way led through the Caudine passes. Supposing the whole Samnite army to be in Apulia, the Romans without precaution entered the first pass, and marched through it without opposition to the plain. When they crossed this, however, and endeavored to pass out through the second de-

file on the opposite side, they found the passage blocked up with stones, trees, earth, and all manner of obstructions. Turning back, they found the gorge by which they had entered filled in the same manner. The Samnites now appeared on the surrounding heights, and the Romans understood the trap into which they had been led. With but little attempt at resistance, they surrendered. The Samnites compelled them all to submit to the disgrace of passing under the yoke (a spear resting across two others fixed upright in the ground), and took the

opportunity of this victory to force the generals to consent to terms of peace, which, although moderate and by no means humiliating, the Roman senate declared void, deciding that Veturius and Postumius had exceeded their authority in consenting to them.

CAUL (Lat. *caula*, a fold), a membrane which sometimes envelopes the head of a child when born. It is of interest only for the superstitious feelings with which it has long been regarded. The child that happened to be born with it was esteemed particularly fortunate; and the possession of it afterward, however obtained, was highly prized, as of a charm of great virtue. The superstition is thought to have come from the East; and according to Weston, in his "Moral Aphorisms from the Arabic," there are several words in that language for it. With the French, *être né coiffé* was an ancient proverb, indicative of the good fortune of the individual. The alchemists ascribed magical virtues to it;

and according to Grose, the health of the person born with it could in after life be judged of by its condition, whether dry and crisp, or relaxed and flaccid. Medicinal virtues are probably still imputed to it by the ignorant, as is the property of preserving the owner of it from drowning.

CAULAINCOURT, Armand Augustin Louis de, duke of Vicenza, a French general and diplomatist, born at Caulaincourt, near Saint-Quentin, in 1773, died in Paris, Feb. 19, 1827. His father, the marquis of Caulaincourt, was a general officer, and the son served in the army from an early age, both in the ranks, under the conscription, and as a staff officer. He was imprisoned for a time after 1792, but followed Gen. Aubert du Bayet to Constantinople in 1797, and made the campaign of 1800 under Gen. Moreau, and those of 1805, 1806, and 1807 under Napoleon. Upon the accession of the emperor Alexander in 1801, he was sent as diplomatic agent to St. Petersburg. He was afterward appointed by Napoleon grand equerry and duke of Vicenza, and in 1807 was sent as ambassador to Russia, in the place of the duke of Rovigo. Being suspected of complicity in the death of the duke d'Enghien, he was coldly received by the Russian nobility, until Alexander wrote him a letter declaratory of his innocence, and gave him special marks of personal esteem. He subsequently disapproved of the foreign policy of Napoleon, and in 1811 asked to be recalled. He also opposed the invasion of Russia. After the burning of Moscow Napoleon chose him as his companion on his flight to France. He was plenipotentiary to the allied sovereigns during the campaign of Saxony, signed the armistice of Pläswitz, June 4, 1813, and was appointed French plenipotentiary to the abortive congress of Prague. He was attached to the person of Napoleon in the campaign that followed. On April 5, 1813, he was made senator, and in September minister of foreign affairs, and in this capacity he went to the congress of Châtillon. When Napoleon seemed about to abdicate, Caulaincourt used his influence with the emperor Alexander to secure the best terms possible, and it is thought that the sovereignty of Elba was secured by his efforts. He signed the treaty of April 11, 1814, and retired to his country seat. On the return of Napoleon in 1815 he was again made minister of foreign affairs. His circular of April 3 to the French diplomats abroad represented the second accession of Napoleon in the best light, and gave assurance of respect for the rights of other nations. He took part in the deliberations of the two chambers in regard to the second abdication, and was a member of the commission of government which preceded the second return of Louis XVIII. His name was upon the list of July 24, but by the influence of the emperor Alexander it was erased. From this time his life was wholly private, except that the old accusation of complicity in the death of the duke d'Enghien was revived;

upon which he published the letter of Alexander exonerating him. This accusation weighed upon him, and he referred to it in his will, protesting his entire innocence. He left unpublished memoirs, said to be of value.

CAULIER, Madeleine, a French peasant girl who during the siege of Lille, Sept. 8, 1708, volunteered to penetrate into the city for the purpose of conveying an important order to Marshal Boufflers. She succeeded in her mission through her brother, who was a soldier in the besieged army. Though Lille was obliged to capitulate (Oct. 23), the duke of Burgundy offered her a reward, which she declined; but she was permitted at her request to enlist in a regiment of dragoons. She displayed great gallantry, and fell in the battle of Denain, July 24, 1712.

CAULIFLOWER (*brassica oleracea botrytis*, De Candolle), a cultivated plant of the cabbage tribe. It has a compact rounded head of delicate flavor, standing on a stalk 18 to 26 inches in height, and surrounded by long leaves. The leaves are not closely packed as in the cabbage.

Cauliflower.

It is more tender than the cabbage, and in transplanting should have a ball of earth lifted with the roots to secure a continuous growth. In the vicinity of New York two crops are raised in the kitchen garden in one season. If the early cauliflower does not come to perfection by the end of June, it will usually fail to head, from the excessive heat at that time. To obtain plants for this crop seeds should be sown in September in good soil, and in about four weeks transplanted to a cold frame, set two or three inches apart, and carefully protected by glass during the winter, being opened to the air only during warm days. In February they should be set into another frame, eight to twelve inches apart, to prevent a spindling growth. They should be transplanted as early in the spring as possible, at a distance of three feet from each other, and well watered and frequently hoed during the dry weather. At the time of heading, the larger leaves may be broken over the head to protect it from the sun, and the waterings should be frequent.

For a late crop the seeds are sown in an open bed in May, and the transplanting is in July. Those plants which do not head before frost may be removed to a warm shed or cellar, covered with coarse litter, and allowed to head during early winter.

CAUMONT, Aldrick Isidore Ferdinand, a French jurist and author, born at Saint Vincent-Cramesnil, May 15, 1825. Despite his poverty he studied law in Paris, and acquired eminence at Havre as a marine lawyer and professor of mercantile jurisprudence. His *Étude sur la vie et les travaux de Hugo Grotius, ou le droit naturel et le droit international* (1862), was crowned by the academy of Toulon. His principal work, consisting of over 50 separate essays, is the *Dictionnaire universel de droit commercial maritime* (1855-69). He published in 1867 *Langue universelle de l'humanité, ou télégraphie parlée par le nombre, réduisant à l'unité tous les idiomes du globe*.

CAURA, a river of Venezuela, formed by the junction of the Yurani, Erevato, and Mareguare. It unites with the Orinoco after a N. course of about 150 m.

CAUS, or Caulx. I. Salomon de, a French engineer, born at or near Dieppe about 1576, died in Paris about 1630. Being a Protestant, he went to England about 1612. From 1614 to 1620 he resided at Heidelberg, as architect to the elector palatine Frederick V., and afterward returned to Paris. There is no historical ground for the story that he died insane in the hospital of Bicêtre. He was one of the foremost physicists of his day; but his writings long remained almost unknown until Arago called attention to them. In his work, *Les raisons des forces mouvantes* (Frankfort, 1615; Paris, 1624; also in German under the title *Von gewaltsamen Bewegungen*, Frankfort, 1615), he gave a plan of an apparatus for raising water by the power of steam. Hence Arago considers him to have been the real inventor of the steam engine. Some have imagined that the marquis of Worcester derived from Caus the idea of the apparatus vaguely described in his "Century of Inventions" (1633), and "Exact and true Definition of the most stupendous Water-commanding Engine, invented by the Right Honorable Edward Somerset, Lord Marquis of Worcester." The other works of Caus are: *La perspective, avec la raison des ombres et miroirs* (London, 1612); *Institution harmonique* (Frankfort, 1615); *Hortus Palatinus* (Heidelberg, 1620); *La pratique et démonstration des horloges solaires* (Paris, 1624). **II. Isaac de**, a relative (perhaps son) of the preceding, a native of Dieppe, was also an engineer and architect, and published among other things, *Nouvelle invention de lever l'eau plus haut que sa source* (London, 1644).

CAUSSIN DE PERCEVAL. I. Jean Jacques Antoine, a French orientalist, born at Montdidier, June 24, 1759, died July 29, 1835. He published good editions of some Arabian works, among which were "Lokman's Fables" and

the first three chapters of the Koran, and various translations of a historical or scientific character. **II. Armand Pierre**, son of the preceding, born in Paris, Jan. 13, 1795, died there in March, 1872. In 1813 he was attached to the French embassy at Constantinople to qualify himself for the post of dragoman, which he subsequently filled at Aleppo, after having explored Asia Minor, and spent a year with the Maronites on Mt. Lebanon. In 1821 he became Arabic professor at the school for modern oriental languages in Paris, and in 1833 he was installed in the chair of philology and Arabic literature at the collège de France. Besides an Arabic grammar and a revised edition of Ellious Boethor's French and Arabic dictionary, he published *Essais sur l'histoire des Arabes avant l'Islamisme, pendant l'époque de Mahomet et jusqu'à la réduction de toutes les tribus sous la loi musulmane* (3 vols. 8vo, Paris, 1847), and translations from the Turkish.

CAUSTICS (Gr. *kaisiv*, fut. *kaiōa*, to burn), or **Escharotics**, substances which destroy the life of the tissues upon which they act. They may be classified according to the depth and nature of their action. Nitric and hydrochloric acids, acid nitrate of mercury, nitrate of silver or lunar caustic, and sulphate of copper remove only a very superficial layer of tissue. Arsenious acid and chloride of zinc cause deeper sloughs, which require several days for their separation. The former agent may under some circumstances be absorbed and give rise to general poisoning. Caustic potassa and strong chromic acid melt down the tissues and leave but little solid slough; hence the neighboring parts should be protected during their application. The first class find a somewhat extensive application in modifying the unhealthy or specific character of an ulcerating surface, and substituting for it a condition of normal granulation. The articles of the second class are sometimes used to remove tumors, and are combined with other ingredients in various cancer cures. Though cases sometimes occur in which, for special reasons, this treatment is allowable, yet in general the knife, if properly used, possesses many advantages over it, especially in the avoidance of pain. The third class are sometimes used for similar purposes, to remove an excess of indurated tissue, or to open an abscess. Caustics are much less used than formerly in the formation of issues for purposes of counter-irritation, or for removing imaginary impurities from the system.

CAUTERETS, a watering place of France, in the department of Hautes-Pyrénées, situated in a fertile basin 3,254 feet above the sea, and enclosed by rugged mountains, 26 m. S. by W. of Tarbes. It has 22 hot sulphur springs whose temperature varies from 102° to 140°. The permanent population is about 1,300; but the number of visitors reaches 15,000 a year.

CAUTLEY, Sir Proby Thomas, an English engineer and palæontologist, born at Roydon in 1802, died at Sydenham, Jan. 25, 1871. He

was the son of a clergyman, studied at the Charterhouse, London, and at Addiscombe, entered the Bengal artillery in 1819, and served in Oude (1820-'21), and at the siege of Bhurtpore (1825-'6). He was subsequently employed in the department of public works in India, and acquired eminence by projecting and completing the Ganges canal (1848-'54). He was knighted after his return to England in 1854, became a member of the Indian council in 1858, and chairman of its committee on public works in 1859. He presented to the British museum a large collection of fossil mammalia, and wrote much on Hindoo palæontology and on kindred topics for the periodicals of scientific societies.

CAUVET, Gilles Paul, a French sculptor and architect, born at Aix, Provence, April 17, 1731, died in Paris, Nov. 15, 1788. He belonged to a rich family and was destined for the law, but indulging his taste for artistic pursuits against the wishes of his parents, he fled to Paris, where he eventually acquired professional eminence. He published in 1777 *Recueil d'ornemens à l'usage des jeunes artistes qui se destinent à la décoration des bâtiments*.

CAVA, a city of Italy, in the province of Salerno, 26 m. S. E. of Naples; pop. in 1872, 19,480. It is the seat of a bishop, suffragan to the pope, and has a cathedral, several other churches, and a convent for gentlewomen. The district is unproductive, but the town flourishes by commerce and by manufactories of silk, cotton, and wool. About one mile from Cava is the celebrated Benedictine monastery of La Trinità di Cava, whose archives contain 40,000 parchment rolls and upward of 60,000 MSS. on paper, 1,600 papal diplomas and bulls, and many rare early printed books. The library also formerly contained a rich collection of MSS., but many of them have been lost or removed.

CAVAIGNAC. I. Jean Baptiste, a French revolutionist, born at Gordon in 1762, died in Brussels, March 24, 1829. In 1792 he was elected to the national convention, where he voted for the death of Louis XVI. As commissioner to the army in La Vendée, and afterward to that in the Pyrenees, he gave evidence of energy and talent. He took part with the Thermidoreans against Robespierre, and was sent on a third mission to the army of the Rhine and Moselle. On the 1st Prairial (May 20), 1795, he commanded the troops who vainly attempted to protect the convention against the insurgents. On the 13th Vendémiaire (Oct. 5) he was assistant to Barras and Bonaparte in repelling the attack by the sections. For a short time he was a member of the council of 500. In 1806 he entered the service of Joseph Bonaparte at Naples, and was continued under Murat. In 1815, during the hundred days, he was prefect of the Somme. On the second restoration, he was expelled from France as a regicide, and took up his residence in Brussels, where he lived in ob-

curity. **II. Éléonore Louis Godefroy**, a French journalist, son of the preceding, born in Paris in 1801, died May 5, 1845. He was one of the most popular leaders of the republican party during the restoration and the reign of Louis Philippe. He distinguished himself in the revolution of July, but upon the elevation of Louis Philippe to the throne he took part in the conspiracy for the overthrow of the new dynasty, and was several times arrested and put on trial. He was one of the founders of the *société des amis du peuple*, and of the *société des droits de l'homme*. After the outbreak of April, 1834, he was arrested and sent to prison, but escaped, July 13, 1835, and retired to Belgium. In 1841 he returned to France, and became one of the editors of the *Réforme*, the most violent of the opposition journals. **III. Louis Eugène**, a French general, brother of the preceding, born in Paris, Oct. 15, 1802, died at his country seat, Château Ournes, department of Sarthe, Oct. 28, 1857. He was educated at the polytechnic school, entered the army as sub-lieutenant of engineers, took part in the French expedition to the Morea, and was appointed to a captaincy in 1829. On the revolution of 1830 he declared for the new order of things, but soon entered the *association nationale*, an organization of the opposition, in consequence of which he was for a while discharged from active service. In 1832 he was sent to Africa. Being intrusted in 1836 with the command of Tlemcen, he held this advanced fortified post for three years against the assaults of the Arabs. In 1839, his health having been impaired, he asked to be placed on leave; he was then a major. A few months later he returned to Africa, where his defence of Cherchell was no less brilliant than that of Tlemcen. In 1840 he was promoted to the colonelcy of the zouaves, and in 1844 he was made brigadier general and governor of the province of Oran. On the revolution of February, 1848, he was appointed governor general of Algeria, and promoted to the rank of general of division. The same year he was elected to the constituent assembly, and was allowed to leave Algeria to take his seat as a representative. He reached Paris two days after the disturbance of May 15, and was immediately appointed minister of war. In a few weeks 75,000 regular troops were gathered within the walls, while 190,000 national guards were ready to support them against the threatened rising of the working classes. Yet the insurrection broke out on the dissolution of the *ateliers nationaux*. On June 22 barricades were erected in the most central parts of the city. Cavaignac concentrated his troops in order finally to bear on the principal points with irresistible force. The assembly having invested him with dictatorial powers, the struggle commenced June 23, and was continued with internecine fury for 70 hours, resulting in a complete government victory. On June 29 Cavaignac resigned his dictatorship,

and the assembly unanimously elected him chief of the executive power. Several propositions, which he declined, were made in the assembly to make him president for four years without recourse to an election. The election for president took place Dec. 10; and out of 7,327,345 votes, Cavaignac received but 1,448,107. After the *coup d'état* of December, 1851, he was arrested and taken to the castle of Ham, his name being placed at the head of the list of the proscribed. Having been set at liberty, he lived for a time in retirement in Belgium, and when he returned to France resided mainly at his country seat in the department of Sarthe. In 1852 he was elected to the legislative body, but refused to take the oath of allegiance to the emperor. In 1857 he was again chosen by the electors of the third district of Paris, but again refused to take the oath. This was the last public act of his life. One morning, as he was leaving the house to visit a friend, he suddenly expired in the arms of an attendant without uttering a word.

CAVAILLON (anc. *Cabellio*), a town of Provence, France, in the department of Vaucluse, on the Durance, 14 m. S. E. of Avignon; pop. in 1866, 8,304. It has an active trade in raw silk, fruits, and preserves, and manufactories of vermicelli and madder. During the revolution its fortifications were destroyed. It was an ancient Roman town, but having been repeatedly pillaged by barbarians, and having suffered much from an earthquake in 1731, it has few remains of antiquity. The most remarkable of its ruins is a triumphal arch supposed to have belonged to the Augustan age. The country round Cavaillon is justly called the garden of Provence.

CAVALCANTI, Guido, an Italian philosopher and poet, born in Florence in the early part of the 13th century, died in 1300. Dante introduces Cavalcanti's father in his *Inferno* on account of his Epicurean philosophy. Cavalcanti was distinguished for the lofty style of his poetry, which consisted for the most part of sonnets and canzonets, the most celebrated of which are those dedicated to Mandetta, a lady whom he had met at Toulouse after his return from a pilgrimage to Compostela. Having married a daughter of the Ghibelline chief Farina degli Uberti, he succeeded his father-in-law as head of that party. When the leaders of both factions were exiled by the citizens, Cavalcanti was sent to Sarzana, where his health was so much injured by the bad air, that he died soon after his return. His *Rime, edite ed inedite*, were published by Cicciporri at Florence in 1813.

CAVALIER, Jean, a leader of the Camisards or insurgent Protestants in the Cévennes, born at Ribaute, in Languedoc, about 1679, died at Chelsea, near London, in May, 1740. The son of a poor peasant, he was first a shepherd, then a baker. Religious persecution forced him to leave his country, but after living a few months at Geneva he secretly went back, and was

foremost among the promoters of the insurrection of 1702. He was at once a preacher and a soldier, and his talents gave him an authority almost equal to that of the Camisard commander-in-chief. When Marshal Villars took the command of the royal troops, Cavalier had an interview with him at Nîmes, and agreed on terms of peace: the young chief was to be received into the king's service, with the rank of colonel and a handsome pension; a regiment was to be raised among the Camisards, who were now to enjoy the free exercise of their religion. This treaty did not suit the other chiefs or the people. Cavalier was immediately discarded by them, and departed for Paris attended by very few companions. There he was treated with contempt by the king; and having received secret advice that he was to be put in prison, he made his escape to Switzerland, whence he went to Holland. Having entered the service of England, he organized a regiment of French refugees, whom he took to Spain to support the cause of Charles. At the battle of Almanza this regiment engaged a battalion of French troops, which fought with such fury that the greatest part of both corps were left dead on the battle field. Cavalier afterward joined the army of Prince Eugene, who entered Provence and besieged Toulon. After the peace of Utrecht he repaired to England, where he was received with great favor, obtaining the rank of general, and being appointed governor of the island of Jersey.

CAVALIERI, or Cavalleri, Bonaventura, an Italian mathematician, born in Milan in 1598, died in Bologna, Dec. 3, 1647. He studied mathematics at Pisa under B. Castelli, a disciple of Galileo, officiated as professor in Bologna, and was author of several mathematical works, the most prominent of which was entitled *Geometria Indivisibilibus*, &c. Having expressed in this work some original ideas concerning the abstruse sciences, the Italians claim him to be the inventor of the infinitesimal calculus.

CAVALLI, Pietro Francesco, an Italian composer, born at Crema about 1599, died in Venice in April, 1676. His real name was Caletti-Bruni, but the governor Cavalli of Crema became his patron; and assuming his name, he became under his auspices chapelmaster of St. Mark's church at Venice. He composed *Serse, L'Orione, L'Ercole amante*, and nearly 40 other operas. According to Dr. Burney, he was the first to introduce in his opera of *Giason* (1649) the ornamental stanza called *aria*.

CAVALLINI, Pietro, an Italian painter, born in Rome, who flourished in the early part of the 14th century. He is said to have been the disciple of Giotto, and is considered the first painter of the Roman school who was worthy of competing with the great Florentine masters. His most celebrated work, the "Crucifixion," is at Assisi. Most of his other works have perished.

CAVALLO, Tiberio, an English electrician, born in Naples in March, 1749, died in London in De-

cember, 1809. He was the son of a Neapolitan physician, completed his education in the university of his native city, and went at an early age to England with a view of becoming a merchant; but he devoted himself to natural philosophy, and gained reputation as a writer and experimenter in electricity and the physical sciences. He invented an instrument called a condenser, and another called a multiplier of electricity, and other instruments. His best work was his "Elements of Natural and Experimental Philosophy" (4 vols. 8vo, London, 1803).

CAVALRY (Fr. *cavalerie*, from *cavalier*, a horseman), a body of soldiers on horseback. The use of the horse for riding, and the introduction of bodies of mounted men into armies, naturally originated in those countries to which the horse is indigenous, and where the climate and gramineous productions of the soil favored the development of all its physical capabilities. While the horse in Europe and tropical Asia soon degenerated into a clumsy animal or an undersized pony, the breed of Arabia, Persia, Asia Minor, Egypt, and the north coast of Africa attained great beauty, speed, docility, and endurance. But it appears that at first it was used in harness only; at least in military history the war chariot long precedes the armed horseman. The Egyptian monuments show plenty of war chariots, but with a single exception no horsemen; and that exception appears to belong to the Roman period. Still it is certain that at least two centuries before the country was conquered by the Persians, the Egyptians had a numerous cavalry, and the commander of this arm is more than once named among the most important officials of the court. It is very likely that the Egyptians became acquainted with cavalry during their war with the Assyrians; for on the Assyrian monuments horsemen are often delineated, and their use in war with Assyrian armies at a very early period is established beyond a doubt. With them, also, the saddle appears to have originated. In the older sculptures the soldier rides the bare back of the animal; at a later epoch we find a kind of pad or cushion introduced, and finally a high saddle similar to that now used all over the East. The Persians and Medians, at the time they appear in history, were a nation of horsemen, though they retained the war chariot, and even left to it its ancient precedence over the newer cavalry. The cavalry of the Assyrians, Egyptians, and Persians consisted of that kind which still prevails in the East, and which up to very recent times was alone employed in northern Africa, Asia, and eastern Europe, irregular cavalry. But no sooner had the Greeks so far improved their breed of horses by crosses with the eastern horse as to fit them for cavalry purposes, than they began to organize the arm upon a new principle. They are the creators of both regular infantry and regular cavalry. They formed the masses of fighting men into distinct bodies,

armed and equipped them according to the purpose for which they were intended, and taught them to act in concert, to move in ranks and files, to keep together in a definite tactical formation, and thus to throw the weight of their concentrated and advancing mass upon a given point of the enemy's front. Thus organized, they proved everywhere superior to the undrilled, unwieldy, and uncontrolled mobs brought against them by the Asiatics. We have no instance of a combat of Grecian cavalry against Persian horsemen before the time the Persians themselves had formed bodies of a more regular kind of cavalry; but there can be no doubt that the result would have been the same as when the infantry of both nations met in battle. Cavalry, at first, was organized only by the horse-breeding countries of Greece, such as Thessaly and Bœotia; but, very soon after, the Athenians formed a body of heavy cavalry, besides mounted archers for outpost and skirmishing duty. The Spartans, too, had the *élite* of their youth formed into a body of horse guards; but they had no faith in cavalry, and made them dismount in battle and fight as infantry. This is the earliest mention made of mounted infantry, which forms so important an element in modern warfare. From the Greeks of Asia Minor, as well as from the Greek mercenaries serving in their army, the Persians learned the formation of regular cavalry, and there is no doubt that a considerable portion of the Persian horse that fought against Alexander the Great were more or less trained to act in compact bodies in a regular manner. The Macedonians, however, were more than a match for them. With that people horsemanship was an accomplishment indispensable to the young nobility, and cavalry held a high rank in their army. The cavalry of Philip and Alexander consisted of the Macedonian and Thessalian nobility, with a few squadrons recruited in central Greece. It was composed of heavy horsemen (*cataphraeti*), armed with helmet and breastplate, cuisses, and a long spear. It usually charged in a compact body, in an oblong or wedge-shaped column, sometimes also in line. The light cavalry, composed of auxiliary troops, was of a more or less irregular kind, and served like the modern Cossacks for outpost duty and skirmishing.—The battle of the Granicus (334 B. C.) offers the first instance of an engagement in which cavalry played a decisive part. The Persian cavalry was placed at charging distance from the fords of the river. As soon as the heads of columns of the Macedonian infantry had passed the river, and before they could deploy, the Persian horse broke in upon them and drove them headlong down into the river. This manœuvre, repeated several times with perfect success, shows at once that the Persians had regular cavalry to oppose to the Macedonians. To surprise infantry in the very moment of its greatest weakness, that is, when passing from one tactical formation into another, requires the

cavalry to be well in hand, and perfectly under the control of its commanders. Irregular levies are incapable of it. Ptolemy, who commanded the advanced guard of Alexander's army, could make no headway until the Macedonian cuirassiers passed the river, and charged the Persians in flank. A long combat ensued, but the Persian horsemen, being disposed in one line without reserves, and being at last abandoned by the Asiatic Greeks in their army, were ultimately routed. The battle of Arbela (331 B. C.) was the most glorious for the Macedonian cavalry. Alexander in person led the Macedonian horse, which formed the extreme right of his order of battle, while the Thessalian horse formed the left. The Persians tried to outflank him, but in the decisive moment Alexander brought fresh men from the rear so as to overlap them in their turn; they at the same time left a gap between their left and centre. Into this gap Alexander at once dashed, separated their left from the remainder of the army, rolled it up completely, and pursued it for a considerable distance. Then, on being called upon to send assistance to his own menaced left, he rallied his horse in a very short time, and passing behind the enemy's centre fell upon the rear of his right. The battle was thus gained, and Alexander from that day ranks among the first of the cavalry generals of all times. And to crown the work, his cavalry pursued the fugitive enemy with such ardor that its advanced guard stood the next day 75 miles in advance of the battle field. It is very curious to observe that the general principles of cavalry tactics were as well understood at that time as they are now. To attack infantry in the formation of the march, or during a change of formation; to attack cavalry principally on its flank; to profit by any opening in the enemy's line by dashing in and wheeling to the right and left, so as to take in flank and rear the troops placed next to such a gap; to follow up a victory by a rapid and inexorable pursuit of the broken enemy—these are among the first and most important rules that every cavalry officer has to learn. After Alexander's death we hear no more of that splendid cavalry of Greece and Macedon. In Greece infantry again prevailed, and in Asia and Egypt the mounted service soon degenerated.—The Romans never were horsemen. What little cavalry they had with the legions was glad to fight on foot. Their horses were of an inferior breed, and the men could not ride. But on the southern side of the Mediterranean a cavalry was formed, which not only rivalled, but even outshone that of Alexander. The Carthaginian generals, Hamilcar and Hannibal, had succeeded in forming, besides their Numidian irregular horsemen, a body of first-rate regular cavalry, and thus created an arm which almost everywhere insured them victory. The Berbers of north Africa are still a nation of horsemen, at least in the plains, and the splendid Barb horse which carried Hannibal's swordsmen

into the deep masses of the Roman infantry, with a rapidity and vehemence unknown before, still mounts the finest regiments of the whole French cavalry, the *chasseurs d'Afrique*, and is by them acknowledged to be the best war horse in existence. The Carthaginian infantry was far inferior to that of the Romans, even after it had been long trained by its two great chiefs; it would not have had the slightest chance against the Roman legions, had it not been for the assistance of that cavalry which alone made it possible for Hannibal to hold out 16 years in Italy; and when this cavalry had been worn out by the wear and tear of so many campaigns, not by the sword of the enemy, there was no longer a place in Italy for him. Hannibal's battles have that in common with those of Frederick the Great, that most of them were won by cavalry over first-rate infantry; and, indeed, at no other time has cavalry performed such glorious deeds as under those two great commanders. From what nation, and upon what tactical principles, Hamilcar and Hannibal formed their regular cavalry, we are not precisely informed. But as their Numidian light horse are always clearly distinguished from the heavy or regular cavalry, we may conclude that the latter was not composed of Berber tribes. There were very likely many foreign mercenaries and some Carthaginians; the great mass, however, most probably consisted of Spaniards, as it was formed in their country, and as even in Cæsar's time Spanish horsemen were attached to most Roman armies. Hannibal being well acquainted with Greek civilization, and Greek mercenaries and soldiers of fortune having before his time served under the Carthaginian standards, there can scarcely be a doubt that the organization of the Grecian and Macedonian heavy cavalry served as the basis for that of the Carthaginian. The very first encounter in Italy settled the question of the superiority of the Carthaginian horse. At the Ticinus (218 B. C.), the Roman consul Publius Scipio, while reconnoitering with his cavalry and light infantry, met with the Carthaginian cavalry led by Hannibal on a similar errand. Hannibal at once attacked. The Roman light infantry stood in first line, the cavalry formed the second. The Carthaginian heavy horse charged the infantry, dispersed it, and then fell at once on the Roman cavalry in front, while the Numidian irregulars charged their flank and rear. The battle was short. The Romans fought bravely, but they had no chance whatever. They could not ride; their own horses vanquished them; frightened by the flight of the Roman skirmishers, who were driven in upon them and sought shelter between them, they threw off many of their riders and broke up the formation. Other troopers, not trusting to their horsemanship, wisely dismounted and attempted to fight as infantry. But already the Carthaginian cuirassiers were in the midst of them, while the inevitable Numidians galloped round the confused mass, cutting down

every fugitive who detached himself from it. The loss of the Romans was considerable, and Publius Scipio himself was wounded. At the Trebia, Hannibal succeeded in enticing the Romans to cross that river, so as to fight with this barrier in their rear. No sooner was this accomplished than he advanced with all his troops against them and forced them to battle. The Romans, like the Carthaginians, had their infantry in the centre; but opposite to the wings of the Roman army, formed by cavalry, Hannibal placed his elephants, making use of his cavalry to outflank and overlap both wings of his opponents. At the very outset of the battle, the Roman cavalry, thus turned and outnumbered, was completely defeated; but the Roman infantry drove back the Carthaginian centre and gained ground. The victorious Carthaginian horse now attacked them in front and flank; they compelled them to desist from advancing, but could not break them. Hannibal, however, knowing the solidity of the Roman legion, had sent 1,000 horsemen and 1,000 picked foot soldiers under his brother Mago by a roundabout way to their rear. These fresh troops now fell upon them and succeeded in breaking the second line; but the first line, 10,000 men, closed up, and in a compact body forced their way through the enemy, and marched down the river toward Placentia, where they crossed it unmolested. In the battle of Cannæ (216 B. C.), the Romans had 80,000 infantry and 6,000 cavalry; the Carthaginians, 40,000 infantry and 10,000 cavalry. The cavalry of Latium formed the Roman right wing, leaning on the river Aufidus; that of the allied Italians stood on the left, while the infantry formed the centre. Hannibal, too, placed his infantry in the centre, the Gallic and Spanish levies again forming the wings, while between them, a little further back, stood his African infantry, now equipped and organized on the Roman system. Of his cavalry, he placed the Numidians on the right wing, where the open plain permitted them, by their superior mobility and rapidity, to evade the charges of the Italian heavy horse opposed to them; while the whole of the heavy cavalry, under Hasdrubal, was stationed on the left, close to the river. On the Roman left, the Numidians gave the Italian cavalry plenty to do. In the centre, the Roman infantry soon drove back the Gauls and Spaniards, and then formed into a wedge-shaped column in order to attack the African infantry. These, however, wheeled inward, and charging the compact infantry in line, broke its impetus; and there the battle now became a standing fight. But Hasdrubal's heavy horse had in the mean time prepared the defeat of the Romans. Having furiously charged the Roman cavalry of the right wing, they dispersed them after a stout resistance, passed, like Alexander at Arbela, behind the Roman centre, fell upon the rear of the Italian cavalry, broke it completely, and, leaving it an easy prey to the Numidians, formed for a grand charge

on the flanks and rear of the Roman infantry. This was decisive. The unwieldy mass, attacked on all sides, gave way, opened out, was broken, and succumbed. Never was there such complete destruction of an army. The Romans lost 70,000 men; of their cavalry, only 70 men escaped. The Carthaginians lost not quite 6,000, three eighths of whom belonged to the Gallic contingents, which had to bear the brunt of the first attack of the legions. Of Hasdrubal's 6,000 regular horse, which had won the whole of the battle, not more than 200 men were killed and wounded. The Roman cavalry of later times was not much better than that of the Punic wars. It was attached to the legions in small bodies, never forming an independent arm. Besides this legionary cavalry, there were in Cæsar's time Spanish, Gallic, and German mercenary horsemen, all of them more or less irregular. No cavalry serving with the Romans ever performed anything worthy of mention; and so neglected and ineffective was this arm, that the Parthian irregulars of Khorasan remained extremely formidable to Roman armies. In the eastern half of the empire, however, the ancient passion for horses and horsemanship retained its sway; and Byzantium remained, up to its conquest by the Turks, the great horse mart and riding academy of Europe. Accordingly, we find that during the momentary revival of the Byzantine empire under Justinian, its cavalry was on a comparatively respectable footing; and in the battle of Capua, in A. D. 552, the eunuch Narses is reported to have defeated the Teutonic invaders of Italy principally by means of this arm.—The establishment, in all countries of western Europe, of a conquering aristocracy of Teutonic origin, led to a new era in the history of cavalry. The nobility took everywhere to the mounted service, under the designation of men-at-arms, forming a body of horse of the heaviest description, in which not only the riders but also the horses were covered with defensive armor. The first battle at which such cavalry appeared was that of Poitiers (732), where Charles Martel beat back the torrent of Arab invasion. The Frankish knighthood, under Eudes, duke of Aquitania, broke through the Moorish ranks and took their camp. But such a body was not fit for pursuit; and the Arabs accordingly, under shelter of their indefatigable irregular horse, retired unmolested into Spain. From this battle dates a series of wars in which the massive but unwieldy regular cavalry of the West fought the agile irregulars of the East with varied success. The German knighthood measured swords, during nearly the whole of the 10th century, with the wild Hungarian horsemen, and totally defeated them by their close array at Merseburg in 933, and at the Lech in 955. The Spanish chivalry for several centuries fought the Moorish invaders of their country, and ultimately conquered them. But when the occidental "heavies" transferred the

seat of war during the crusades to the eastern homes of their enemies, they were in their turn defeated, and in most cases completely destroyed; neither they nor their horses could stand the climate, the immensely long marches, and the want of proper food and forage. These crusades were followed by a fresh irruption of eastern horsemen into Europe, that of the Mongols, who, under the leadership of the great khans, organized cavalry armies numbering according to Marco Polo as many as 300,000 men. Having overrun Russia and the provinces of Poland, they were met at Wahlstadt in Silesia, in 1241, by a combined Polish and German army. After a long struggle, the Asiatics defeated the worn-out steel-clad knights, but the victory was so dearly bought that it broke the power of the invaders. The Mongols advanced no further, and soon, by divisions among themselves, ceased to be dangerous, and were driven back. During the whole of the middle ages cavalry remained the chief arm of all armies; with the eastern nations the light irregular horse had always held that rank; with those of western Europe, the heavy regular cavalry formed by the knighthood was in this period the arm which decided every battle. This preëminence of the mounted arm was not so much caused by its own excellence, for the irregulars of the East were incapable of orderly fight, and the regulars of the West were incredibly clumsy in their movements; it was principally caused by the bad quality of the infantry. Asiatics as well as Europeans held that arm in contempt; it was composed of those who could not afford to appear mounted, principally of slaves or serfs. There was no proper organization for it; without defensive armor, with a pike and sword for its sole weapons, it might now and then by its deep formation withstand the furious but disorderly charges of eastern horsemen; but it was easily ridden over by the invulnerable men-at-arms of the West. The only exception was formed by the English infantry, which derived its strength from its formidable weapon, the long-bow. The numerical proportion of the European cavalry of these times to the remainder of the army was certainly not as great as it was a few centuries later, nor even as it is now. Knights were not so exceedingly numerous, and in many large battles we find that not more than 800 or 1,000 of them were present. But they were generally sufficient to dispose of any number of foot soldiers, as soon as they had succeeded in driving from the field the enemy's men-at-arms. The general mode of fighting of these men-at-arms was in line, in single rank, the rear rank being formed by the esquires, who usually wore a less complete and heavy suit of armor. These lines, once in the midst of the enemy, soon dissolved themselves into single combatants, and finished the battle by sheer hand-to-hand fighting. Subsequently, when firearms began to come into use, deep masses were formed, generally squares; but then the

days of chivalry were numbered. During the 15th century, not only was artillery generally introduced into the field of battle, while part of the infantry, the skirmishers of those times, were armed with muskets, but a general change took place in the character of the infantry. This arm began to be formed by the enlistment of mercenaries who made war a profession. The German *Landsknechte* and the Swiss were such professional soldiers, and they very soon introduced more regular formations and tactical movements. The ancient Doric and Macedonian phalanx was in a manner revived; a helmet and a breastplate somewhat protected the men against the lance and sword of the cavalry; and when, at Novara (1513), the Swiss infantry drove the French knighthood from the field, there was no further use for such valiant but unwieldy horsemen. Accordingly, after the insurrection of the Netherlands against Spain, we find a new class of cavalry, the German *Reiter* (*reitres* of the French), raised by voluntary enlistment, like the infantry, and armed with helmet and breastplate, sword and pistols. They were fully as heavy as the modern cuirassiers, yet far lighter than the knights. They soon proved their superiority over the heavy men-at-arms. These now disappear, and with them the lance; the sword and short firearms now form the general armature for cavalry. About the same time (end of the 16th century) the hybrid arm of dragoons was introduced, first in France, then in the other countries of Europe. Armed with muskets, they were intended to fight, according to circumstances, either as infantry or as cavalry. A similar corps had been formed by Alexander the Great under the name of *dimacha*, but it had not yet been imitated. The dragoons of the 16th century had a longer existence, but toward the middle of the 18th century they had everywhere lost their hybrid character, except in name, and were generally used as cavalry. The most important feature in their formation was that they were the first body of regular cavalry which was completely deprived of defensive armor. The creation of real hybrid dragoons was again attempted, on a large scale, by the emperor Nicholas of Russia; but it was soon proved that before the enemy they must always be used as cavalry, and consequently Alexander II. very soon reduced them to simple cavalry, with no more pretensions to dismounted service than hussars or cuirassiers. Maurice of Orange, the great Dutch commander, formed his reiters for the first time in something like our modern tactical organization. He taught them to execute charges and evolutions in separate bodies, and in more than one line; to wheel, break off, form column and line, and change front, without disorder, and in separate squadrons and troops. Thus a cavalry fight was no longer decided by one charge of the whole mass, but by the successive charges of separate squadrons and lines supporting each

other. His cavalry was formed generally five deep. In other armies it fought in deep bodies, and where a line formation was adopted it was still from five to eight deep. The 17th century, having completely done away with the costly men-at-arms, increased the numerical strength of cavalry to an enormous extent. At no other period was there so large a proportion of that arm in every army. In the thirty years' war from two fifths to nearly one half of each army was generally composed of cavalry; in single instances there were two horsemen to one foot soldier. Gustavus Adolphus stands at the head of cavalry commanders of this period. His mounted troops consisted of cuirassiers and dragoons, the latter fighting almost always as cavalry. His cuirassiers, too, were much lighter than those of the emperor, and soon proved their incontestable superiority. The Swedish cavalry were formed three deep; their orders were, contrary to the usage of the cuirassiers of most armies, whose chief arm was the pistol, not to lose time in firing, but to charge the enemy sword in hand. At this period the cavalry, which during the middle ages had generally been placed in the centre, was again placed, as in antiquity, on the wings of the army, where it was formed in two lines. In England, the civil war gave rise to two distinguished cavalry leaders. Prince Rupert, on the royalist side, had as much "dash" in him as any cavalry general, but he was almost always carried too far, lost his cavalry out of hand, and was himself so taken up with what was immediately before him, that the general always disappeared in the "bold dragoon." Cromwell, on the other hand, with quite as much dash where it was required, was a far better general; he kept his men well in hand, always held back a reserve for unforeseen events and decisive movements, knew how to manœuvre, and thus proved generally victorious over his more inconsiderate opponent. He won the battles of Marston Moor and Naseby by his cavalry alone.—With most armies the use of the firearm still remained the chief employment of cavalry in battle, the Swedes and English alone excepted. In France, Prussia, and Austria, cavalry was drilled to use the carbine exactly as infantry used the musket. They fired on horseback, the line standing still all the while, by files, platoons, ranks, &c.; and when a movement for a charge was made, the line advanced at a trot, pulled up at a short distance from the enemy, gave a volley, drew swords, and then charged. The effective fire of the long lines of infantry had shaken all confidence in the charge of a cavalry which was no longer protected by armor; consequently, riding was neglected, no movements could be executed at a quick pace, and even at a slow pace frequent accidents happened to both men and horses. The drill was mostly dismounted work, and their officers had no idea whatever of the way of handling cavalry in battle. The French, it is true, sometimes charged sword in hand, and

Charles XII. of Sweden, true to his national tradition, always charged full speed without firing, dispersing cavalry and infantry, and sometimes even taking field works of a weak profile. But it was reserved for Frederick the Great and his great cavalry commander, Seydlitz, to revolutionize the mounted service, and to raise it to the culminating point of glory. The Prussian cavalry, heavy men on clumsy horses, drilled for firing only, such as Frederick's father had left them to his son, were beaten in an instant at Mollwitz (1741). But no sooner was the first Silesian war brought to a close than Frederick entirely reorganized his cavalry. Firing and dismounted drill were thrown into the background, and riding was attended to. "All evolutions are to be made with the greatest speed, all wheels to be done at a canter. Cavalry officers must above all things form the men into perfect riders; the cuirassiers to be as handy and expert on horseback as a hussar, and well exercised in the use of the sword." The men were to ride every day. Riding in difficult ground, across obstacles, and fencing on horseback, were the principal drills. In a charge, no firing at all was allowed until the first and second lines of the enemy were completely broken. "Every squadron, as it advances to the charge, is to attack the enemy sword in hand, and no commander shall be allowed to let his troops fire under penalty of infamous cashiering; the generals of brigades to be answerable for this. As they advance, they first fall into a quick trot, and finally into a full gallop, but well closed; and if they attack in this way, his majesty is certain that the enemy will always be broken." "Every officer of cavalry will have always present to his mind that there are but two things required to beat the enemy: 1, to charge him with the greatest possible speed and force; and, 2, to outflank him." These passages from Frederick's instructions sufficiently show the total revolution he carried out in cavalry tactics. He was seconded admirably by Seydlitz, who always commanded his cuirassiers and dragoons, and made such troops of them that for vehemence and order of charge, quickness of evolutions, readiness for flank attacks, and rapidity in rallying and reforming after a charge, no cavalry has ever equalled the Prussian cavalry of the seven years' war. The fruits were soon visible. At Hohenfriedberg the Baireuth regiment of dragoons, 10 squadrons, rode down the whole left wing of the Austrian infantry, broke 21 battalions, took 66 stand of colors, 5 guns, and 4,000 prisoners. At Zorndorf, when the Prussian infantry had been forced to retreat, Seydlitz, with 36 squadrons, drove the victorious Russian cavalry from the field, and then fell upon the Russian infantry, completely defeating it with great slaughter. At Rossbach, Striegau, Kesselsdorf, Lenthén, and in ten other battles, Frederick owed the victory to his splendid cavalry.—When the French revolutionary war broke out, the Austrians had adopted the Prussian system,

but not so the French. The cavalry of the latter nation had, indeed, been much disorganized by the revolution, and in the beginning of the war the new formations proved almost useless. When their new infantry levies were met by the good cavalry of the English, Prussians, and Austrians, they were, during 1792 and 1793, almost uniformly beaten. The cavalry, quite unable to cope with such opponents, was always kept in reserve until a few years' campaigning had improved them. In 1796 and afterward every division of infantry had cavalry as a support; still, at Würzburg, the whole of the French cavalry was defeated by 59 Austrian squadrons (1796). When Napoleon took the direction of affairs in France, he did his best to improve the French cavalry. He found about the worst material that could be met with. As a nation, the French were the worst horsemen of Europe, and their horses, good for draught, were not well adapted for the saddle. He made great improvements, and after the camp of Boulogne his cavalry, in great part mounted on German and Italian horses, was no despicable adversary. The campaigns of 1805 and 1806-7 allowed his cavalry to absorb almost all the horses of the Austrian and Prussian armies, and moreover reënforced the French army by the excellent cavalry of the confederation of the Rhine and the duchy of Warsaw. Thus were formed those enormous masses of horsemen with which Napoleon acted in 1809, 1812, and the latter part of 1813, which, though generally designated as French, were in great part composed of Germans and Poles. The cuirass, which had been entirely done away with in the French army shortly before the revolution, was restored to a portion of the heavy cavalry by Napoleon. In other respects the organization and equipment remained nearly the same, except that with his Polish auxiliaries he received some regiments of light horse, armed with the lance, the costume and equipment of which were soon imitated in other armies. But in the tactical use of cavalry he introduced a complete change. According to the system of composing divisions and army corps of all three arms, a portion of the light cavalry was attached to each division or corps; but the mass of the arm, and especially all the heavy horse, were held together in reserve for the purpose of striking at a favorable moment a great decisive blow, or, in case of need, of covering the retreat of the army. These masses of cavalry, suddenly appearing on a given point of the battle field, have often acted decisively; still they never gained such brilliant successes as the horsemen of Frederick the Great. The cause of this is to be looked for partly in the changed tactics of infantry, which, by selecting chiefly broken ground for its operations, and always receiving cavalry in a square, made it more difficult for the latter arm to achieve such great victories as the Prussian horsemen had obtained over the long, thin infantry lines of their opponents.

But it is also certain that Napoleon's cavalry was not equal to that of Frederick the Great, and that Napoleon's cavalry tactics were not in every instance an improvement upon those of Frederick. The indifferent riding of the French compelled them to charge at a comparatively slow pace, at a trot or a collected canter; there are but few instances where they charged at a gallop. Their great bravery and close ranks made up often enough for the curtailed impetus, but still their charge was not what would now be considered good. The old system of receiving hostile cavalry standing, carbine in hand, was in very many cases retained by the French cavalry, and in every such instance were they defeated. The last example of this happened at Danigkow, April 5, 1813, where about 1,200 French cavalry thus awaited a charge of 400 Prussians, and were completely beaten in spite of their numbers. As to Napoleon's tactics, the use of great masses of cavalry with him became such a fixed rule, that not only was the divisional cavalry weakened so as to be completely useless, but also in the employment of these masses he often neglected that successive engagement of his forces which is one of the principal points in modern tactics, and which is even more applicable to cavalry than to infantry. He introduced the cavalry charge in column, and even formed whole cavalry corps into one monster column, in such formations that the extrication of a single squadron or regiment became an utter impossibility, and that any attempt at deploying was entirely out of the question. His cavalry generals, too, were not up to the mark, and even the most brilliant of them, Murat, would have cut but a sorry figure if opposed to a Seydlitz. During the wars of 1813, '14, and '15, cavalry tactics had decidedly improved on the part of Napoleon's opponents. Though to a great extent following Napoleon's system of holding cavalry in reserve in large masses, and therefore very often keeping the greater portion of the cavalry entirely out of an action, still in many instances a return to the tactics of Frederick was attempted. In the Prussian army the old spirit was revived. Blücher was the first to use his cavalry more boldly, and generally with success. The ambuscade of Haynau (1813), where 20 Prussian squadrons rode down 8 French battalions and took 18 guns, marks a turning point in the modern history of cavalry, and forms a favorable contrast to the tactics of Lützen, where the allies held 18,000 horse entirely in reserve until the battle was lost, although a more favorable cavalry ground could not be found. The English had never adopted the system of forming large masses of cavalry, and had therefore many successes, although Napier himself admits that their cavalry was not so good at that time as that of the French. At Waterloo, where the French cuirassiers for once charged at full speed, the English cavalry was admirably handled and generally successful, except where it followed

its national weakness of getting out of hand. Since the peace of 1815, Napoleon's tactics, though still preserved in the regulations of most armies, have again made room for those of Frederick.—Noticeable advancement in the proper organization and use of cavalry was made in the United States during the civil war, the men of both armies, as well as the horses of all sections, being admirably adapted to this branch of the military service. At first the confederate cavalry had the advantage both in organization and commanders, and yet took no very important part in the battles which were fought. A large number of cavalry regiments were organized by both armies, but being composed of men almost entirely ignorant of military life, they were at first used for scouts, orderlies, and outpost service, and were attached to corps, and in some cases to divisions of infantry. Gen. Hooker, while in command of the army of the Potomac, collected the cavalry into a corps, and made an effort to use it in connection with the infantry in battle, but met with no success worthy of record. In the west the practice and result were similar, but attention was drawn to the cavalry by the successful march of a small brigade of horse under Col. Grierson from the neighborhood of Memphis, through Mississippi, to Port Gibson. But the first successful organization of the cavalry was made under the direction of Gen. Grant, by Gen. Sheridan, who was placed in command of all the mounted troops serving with the army of the Potomac. This organization was known as the cavalry corps of the army of the Potomac, and consisted of three divisions each about 5,000 strong, or of two or three brigades of three or four regiments each. They were mostly armed with repeating carbines and sabres, and habitually fought on foot, though they showed a partiality for charging with the sabre when opportunity offered. Up to this period of the war (the spring of 1864) the improvements in the organization and use of cavalry kept even pace with each other in the contending armies; but Gen. Grant having detached Sheridan with his entire force after the battle of Spottsylvania Court House, the latter met and defeated the confederate cavalry at Yellow Tavern, near Richmond, killing their leader, Gen. Stewart, and ever after, till the termination of the war, retained his superiority over his opponents, increased the efficiency of his own troops, and made them an important portion of the army, taking an essential part in all the campaigns and battles. The battle of the Opequan, near Winchester, in which Sheridan defeated Early, was begun and ended by the cavalry, Wilson's division having broken through the enemy's picket line and under cover of darkness secured the position upon which the battle was mainly fought, while Merritt's division, later in the day, turned the enemy's right, and, aided by the advance of the infantry, swept the confederate infantry from the field. The part taken by the cavalry in the final battles

near Petersburg, and especially at Five Forks, and in the capture of the confederate army near Appomattox Court House, was no less conspicuous and important. The western armies had with them a large number of mounted regiments, which were organized at various times into brigades and divisions, but none of the commanding generals seemed to appreciate their value, or to know how to use them effectively. Sherman made several efforts to concentrate the mounted regiments and to give them a coherent organization, but met with nothing but disappointment, till Gen. Grant sent Gen. Wilson to take the place of chief of cavalry. Sherman gave this officer a *carte blanche*, and put him in command of 72 regiments (each nominally 1,200 strong), comprising all the cavalry and mounted infantry of the armies of the Ohio, Cumberland, and Tennessee. Gen. Wilson organized these regiments, after mustering out and disbanding a number, into seven divisions, mostly of two brigades each, forming a corps designated as the cavalry corps of the military division of the Mississippi. At the time of its organization (on paper), in October, 1864, the troops constituting it were scattered from Gaylesville, Alabama, to the Big Blue river in Missouri, and were mostly dismounted. They had worn out their horses by hard usage, and the war department had so little confidence in the utility of this arm of service, that it made but feeble efforts to furnish horses for a remount, so long as they were to be used as they had been heretofore. The success of Sheridan in the army of the Potomac, however, gave renewed confidence, and the war department made extraordinary efforts to secure horses. The secretary of war authorized the cavalry to seize and impress horses wherever they could be found. Meanwhile Sherman had marched toward the sea, and Hood had invaded Tennessee, and pressed back the forces of Gen. Schofield to Franklin, where a stand was made, and a decided victory gained both by the infantry and cavalry over the corresponding arms under Hood and Chalmers. During the 15 days of the siege of Nashville Wilson increased his effective mounted force, by the impressment of horses and the use of remounts forwarded from the north, from 5,000 to 15,000. At the battle of Nashville, on the 15th and 16th of December, he had 12,000 mounted cavalry and infantry, besides 3,000 dismounted men, and a detached force of 3,000 men operating in Kentucky. During the first day's operations he turned the left wing of Hood's army, capturing 16 guns and many prisoners, and on the second day continued his operations upon the left wing and rear of the enemy, pressing them by repeated charges of his dismounted horsemen under Hatch, Coon, and Hammond, till Hood sent word to Chalmers, "For God's sake drive the Yankee cavalry from our left and rear, or all is lost." But Chalmers failed, and by nightfall the confederate army was broken, scattered, and in full retreat. The cavalry pursued with vigor,

and, notwithstanding the swollen streams and wintry weather, did not relinquish the chase till the remnant of Hood's army had crossed the Tennessee river. Wilson's corps went into cantonments on the banks of the river, below the Muscle shoals at the head of navigation, early in January, about 7,000 effectives. During the next six weeks the number was increased to 27,000 men, 17,000 of whom were mounted and thoroughly equipped. This did not include Kilpatrick's division, then detached with Sherman. A system of drills and instruction was instituted, the single-rank formation prescribed by the new tactics was discarded, and the double-rank adopted, as being better calculated for manœuvring so large a command in a thickly wooded country. After detaching one division of 5,000 men to join Canby in Louisiana, and leaving another in camp dismounted, 8,000 strong, Wilson marched from Eastport toward Selma on the 22d of March with nearly 15,000 men, 12,000 of whom were well mounted, and 3,000 dismounted. All of these men, except about 1,200, were armed with the Spencer magazine carbines or rifles. On the 2d day of April they arrived in front of Selma, having met and defeated a part of Forrest's cavalry the day before. This place, although strongly fortified by a continuous line of earthworks and stockades, and defended by 32 guns and nearly 8,000 men, composed about equally of regular troops and militia, was assaulted and captured, the principal attacking force consisting of 1,550 men and officers. After bridging the Alabama river, this corps marched rapidly through Montgomery toward Macon, Georgia, capturing on the way West Point and Columbus, the former by assault during the daytime, and the latter by a night attack conducted under the immediate supervision of Generals Upton and Winslow. On April 20 it reached Macon, where it was arrested by the termination of the war. Up to this time it had subsisted upon the country, marched 525 miles in 28 days, captured 6,820 prisoners and 280 guns, and destroyed two gunboats, 99,000 stands of small arms, 235,000 bales of cotton, and all the mills, collieries, iron works, factories, railroad bridges, rolling stock, and military establishments which were found on the line of march. The lessons taught by the operations of the national cavalry during the closing events of the civil war are not new, but they seem to have been neglected by the European commanders of the present time. They are, that cavalry should constitute a large part of the army in time of war, and be so organized, mounted, equipped, and directed as to act with vigor and celerity upon the flanks, rear, and communications of the enemy. It should be armed with magazine rifles and carbines, using cartridges with metallic cases, march with great rapidity, at the rate of 40 or 50 miles per day, and fight generally dismounted like light infantry. It should usually subsist upon the enemy's country, and on long marches, or in the presence of the enemy, have no trains except

for the purpose of carrying extra ammunition. It should be kept in large bodies and be used mainly for great purposes. Properly handled and organized, it is capable of doing almost all the services of infantry, besides marching with twice or thrice their rapidity.—In modern European armies riding is better attended to than formerly, though still not at all to the extent it should be. The idea of receiving the enemy carbine in hand is scouted; Frederick's rule is everywhere revived, that every cavalry commander who allows the enemy to charge him, instead of charging himself, deserves to be cashiered. The gallop is again the pace of the charge; and the column attack has made way for charges in successive lines, with dispositions for flank attack, and with a possibility of manœuvring with single detachments during the charge. Still much remains to be done before the European cavalry can claim to have caught the spirit of the American improvement in the use of this great arm. The cavalry took but a comparatively insignificant part in the last great wars between Prussia and Austria and between Prussia and France. It may be said that neither of the combatants showed any appreciation of the immense advantages to be gained by using mounted troops in masses, upon the flank and rear of the enemy.—From the history of cavalry let us now turn to its present organization and tactics. The recruiting of cavalry, as far as the men are concerned, is not different upon the whole from the way the other arms recruit themselves in each country. In some states, however, the natives of particular districts are destined to this service; thus in Russia, the Malorussians (natives of Little Russia); in Prussia, the Poles. In Austria, the heavy cavalry is recruited in Bohemia, the hussars exclusively in Hungary, and the lancers (ulans) mostly in Galicia. The recruiting of the horses, however, deserves especial notice. In England, where the whole cavalry does not require in time of war above 10,000 horses, the government finds no difficulty in buying them; but in order to insure to the service the benefit of horses not worked till nearly five years old, three-year-old colts, mostly Yorkshire bred, are bought and kept at government expense in depots till they are fit to be used. The price paid for the colts (£20 to £25), and the abundance of good horses in the country, make the British cavalry certainly the best mounted in the world. In Russia a similar abundance of horses exists, though the breed is inferior to the English. The remount officers buy the horses by wholesale in the southern and western provinces of the empire; they resell those that are unfit, and hand over to the various regiments such as are of its color (all horses being of the same color in a Russian regiment). The colonel is considered as it were proprietor of the horses; for a round sum paid to him he has to keep the regiment well mounted. The horses are expected to last eight years. Formerly they were

taken from the large breeding establishments of Volhynia and the Ukraine, where they are quite wild; but breaking them for cavalry purposes was so difficult that it had to be given up. In Austria the horses are partly bought, but the greater portion have of late been furnished by the government breeding establishments, which can part every year with above 5,000 five-year-old cavalry horses. For a case of extraordinary effort, a country so rich in horses as Austria can rely upon the markets of the interior. Prussia at the beginning of the century had to buy almost all her horses abroad, but now can mount the whole of her cavalry, line and landwehr, in the interior. For the line, the horses are bought at three years old, by remount commissaries, and sent into depots until old enough for service; 3,500 are required every year. In case of mobilization of the landwehr cavalry, all horses in the country, like the men, are liable to be taken for service; a compensation of from \$40 to \$70 is however paid for them. There are three times more serviceable horses in the country than can be required. France, of all European countries, is the worst off for horses. The breed, though often good and even excellent for draught, is generally unfit for the saddle. Government breeding studs (*haras*) have been long established, but not with the success they have had elsewhere. Though the depots and studs have been much improved, they are still insufficient to fully supply the army. Algeria furnishes a splendid breed of cavalry horses, and the best regiments of the service, the *chasseurs d'Afrique*, are exclusively mounted with them, but the other regiments scarcely get any. Thus, in case of a mobilization, the French are compelled to buy abroad.—Cavalry is essentially of two kinds: heavy and light. The real distinctive character of the two is in the horses. Large and powerful horses cannot well work together with small, active, and quick ones. The former in a charge act less rapidly, but with greater weight; the latter act more by the speed and impetuosity of the attack, and are moreover far more fit for single combat and skirmishing, for which heavy or large horses are neither handy nor intelligent enough. Thus far the distinction is necessary; but fashion, fancy, and the imitation of certain national costumes, have created numerous subdivisions and varieties, to notice which in detail would be of no interest. The heavy cavalry, at least in part, is in most countries furnished with a cuirass, which, however, is far from being shot-proof. Light cavalry is partly armed with the sword and carbine, partly with the lance. The carbine is now generally rifled. Pistols are added in most cases to the armature of the rider; the United States cavalry alone carries the revolver. The sword is either straight, or curved to a greater or less degree; the first preferable for thrusts, the second for cuts. The question as to the advantages of the lance over the sword is still under discussion. For close encounter

the sword is undoubtedly preferable; and in a charge the lance, unless too long and heavy to be easily wielded, can scarcely act at all, but in the pursuit of broken cavalry it is most effective. Of nations of horsemen, almost all trust to the sword; even the Cossack abandoned his lance when he had to fight against the expert swordsmen of Circassia. The carbine is very effective if rifled, and more so if it is a breech-loading one furnished with a magazine; the revolver in skilful hands is a formidable weapon for close encounter.—Besides the saddle, bridle, and armed rider, the cavalry horse has to carry a valise with reserve clothing, camp utensils, grooming tackle, and in a campaign also food for the rider and forage for itself. The sum total of this burden varies in different services and classes of cavalry, between 250 and 300 lbs. for the heavy marching order, a weight which will appear enormous when compared with what private saddle horses have to carry. This overweighting of horses is the weakest point of all cavalry. Great reforms are everywhere required in this respect. The weight of the men and accoutrements can and must be reduced; but as long as the present system lasts, this drag upon the horses is always to be taken into account whenever we judge of the capabilities of exertion and endurance of cavalry. Heavy cavalry, composed of strong but, if possible, comparatively light men, on strong horses, must act principally by the force of a well closed, solid charge. This requires power, endurance, and a certain physical weight, though not as much as would render it unwieldy. There must be speed in its movements, but no more than is compatible with the highest degree of order. Once formed for the attack, it must chiefly ride straight forward; but whatever comes in its path must be swept away by its charge. The riders need not be individually as good horsemen as those of light cavalry; but they must have full command over their horses, and be accustomed to ride straight forward and in a well closed mass. Their horses, in consequence, must be less sensible to the leg, nor should they have their haunches too much under them; they should step out well in their trot, and be accustomed to keep well together in a good, long hand gallop. Light cavalry, on the contrary, with nimbler men and quicker horses, has to act by its rapidity and ubiquity. What it lacks in weight must be made up by speed and activity. It will charge with the greatest vehemence; but when preferable, it will seemingly fly in order to fall upon the enemy's flank, by a sudden change of front. Its superior speed and fitness for single combat render it peculiarly fit for pursuit. Its chiefs require a quicker eye and a greater presence of mind than those of heavy horse. The men must be individually better horsemen; they must have their horses perfectly under control, start from a stand into a full gallop, and again stop in an instant; turn quick, and leap well;

the horses should be hardy and quick, light in the mouth, and obedient to the leg, handy at turning, and especially broken for working at a canter, having their haunches well under them. Besides rapid flank and rear attacks, ambuscades, and pursuit, the light cavalry has to do the greater part of the outpost and patrolling duty for the whole army; aptness for single combat, the foundation of which is good horsemanship, is therefore one of its principal requirements. In line, the men ride less close together, so as to be always prepared for changes of front and other evolutions. In the United States army there are 10 regiments of cavalry, all of which are really mounted infantry.—The tactical unity in cavalry is the squadron, comprising as many men as the voice and immediate authority of one commander can control during evolutions. The strength of a squadron varies from 100 men in England to 200 men in France; those of the other armies also being within these limits. A regiment comprises 4, 6, 8, 10, or 12 squadrons. The weakest regiments are the English, 400 to 480 men; the strongest the Austrian light horse, 1,600 men. Strong regiments are apt to be unwieldy; too weak ones are very soon reduced by a campaign. Thus the British light brigade at Balaklava, not two months after the opening of the campaign, numbered in five regiments of two squadrons each scarcely 700 men, or just half as many as one Russian hussar regiment on the war footing. Peculiar formations are: with the British the troop or half squadron, and with the Austrians the division or double squadron, an intermediate link which alone renders it possible for one commander to control their strong regiments of horse.—Before Frederick the Great, all cavalry was formed at least three deep. He first formed his hussars, in 1743, two deep, and at the battle of Rossbach had his heavy horse formed the same way. After the seven years' war this formation was adopted by all other armies, and is the only one now in use. For purposes of evolution the squadron is divided into four divisions. Wheeling from line into open column of divisions, and back into line from column, form the chief and fundamental evolution of all cavalry manœuvres. Most other evolutions are only adapted either for the march (the flank march by three, &c.), or for extraordinary cases (the close column by divisions or squadrons). The action of European cavalry in battle is generally a hand-to-hand encounter; its fire is of subordinate importance; steel, either sword or lance, is its chief weapon; and all cavalry action is concentrated in the charge. Thus the charge is the criterion for all movements, evolutions, and positions of cavalry. Whatever obstructs the facility of charging is faulty. The impetus of the charge is produced by concentrating the highest effort both of man and horse into its crowning moment, the moment of actual contact with the enemy. In order to effect this, it is necessary to approach the enemy with a gradually in-

creasing velocity, so that the horses are put to their full speed at a short distance from the enemy only. The execution of such a charge is about the most difficult matter that can be asked from cavalry. It is extremely difficult to preserve perfect order and solidity in an advance at increasing pace, especially if there is much not quite level ground to go over. The difficulty and importance of riding straight forward is here shown; for unless every rider rides straight to his point, there arises a pressure in the ranks, which is soon rolled back from the centre to the flanks, and from the flanks to the centre; the horses get excited and uneasy, their unequal speed and temper come into play, and soon the whole line is straggling along in anything but a straight alignment, and with anything but that closed solidity which alone can insure success. Then, on arriving in front of the enemy, it is evident that the horses will attempt to refuse running into the standing or moving mass opposite, and that the riders must prevent their doing so; otherwise the charge is sure to fail. The rider, therefore, must not only have the firm resolution to break into the enemy's line, but he must also be perfectly master of his horse. The regulations of different armies give various rules for the mode of advance of the charging cavalry, but they all agree in this point, that the line, if possible, begins to move at a walk, then trot, at from 300 to 150 yards from the enemy canter, gradually increasing to a gallop, and at from 20 to 30 yards from the enemy full speed. All such regulations, however, are subject to many exceptions; the state of the ground, the weather, the condition of the horses, &c., must be taken into consideration in every practical case. If in a charge of cavalry against cavalry both parties actually meet, which is by far the most uncommon case in cavalry engagements, the swords are of little avail during the actual shock. It is the momentum of one mass which breaks and scatters the other. The moral element, bravery, is here at once transformed into material force; the bravest squadron will ride on with the greatest self-confidence, resolution, rapidity, *ensemble*, and solidity. Thus it is that no cavalry can do great things unless it has plenty of "dash" about it. But as soon as the ranks of one party are broken, the swords, and with them individual horsemanship, come into play. A portion at least of the victorious troop has also to give up its tactical formation, in order to mow with the sword the harvest of victory. Thus the successful charge at once decides the contest; but unless followed up by pursuit and single combat, the victory would be comparatively fruitless. It is this immense preponderance of the party which has preserved its tactical compactness and formation, over the one which has lost it, that explains the impossibility for irregular cavalry, be it ever so good and so numerous, to defeat regular cavalry. There is no doubt that so far as individual horsemanship and swordmanship is concerned, no regular

cavalry ever approach the irregulars of the nations of horse warriors of the East; and yet the very worst of European regular cavalries has always defeated them in the field. From the defeat of the Huns at Châlons (451) to the sepoy mutiny of 1857, there is not a single instance where the splendid but irregular horsemen of the East have broken a single regiment of regular cavalry in an actual charge. Their irregular swarms, charging without concert or compactness, cannot make any impression upon the solid, rapidly moving mass. Their superiority can only appear when the tactical formation of the regulars is broken, and the combat of man to man has its turn; but the wild racing of the irregulars toward their opponents can have no such result. It has only been when regular cavalry, in pursuit, have abandoned their line formation and engaged in single combat, that irregulars, suddenly turning round and seizing the favorable moment, have defeated them; indeed, this stratagem has made up almost the whole of the tactics of irregulars against regulars, ever since the wars of the Parthians and the Romans. Of this there is no better example than that of Napoleon's dragoons in Egypt, undoubtedly the worst regular cavalry then existing, which defeated in every instance the most splendid of irregular horsemen, the Mamelukes. Napoleon said of them, two Mamelukes were decidedly superior to three Frenchmen; 100 Frenchmen were a match for 100 Mamelukes; 300 Frenchmen generally beat 300 Mamelukes; 1,000 Frenchmen in every instance defeated 1,500 Mamelukes. However great may be the superiority in a charge of that body of cavalry which best preserves its tactical formation, it is evident that even this body must, after the successful charge, be comparatively disordered. The success of the charge is not equally decisive on every point; many men are irretrievably engaged in single combat or pursuit; and it is comparatively but a small portion, mostly belonging to the second rank, who remain in some kind of line. This is the most dangerous moment for cavalry; a very small body of fresh troops, thrown upon it, would snatch the victory from its hands. To rally quickly after a charge is therefore the criterion of a really good cavalry, and it is in this point that not only young but also otherwise experienced and brave troops are deficient. The British cavalry, riding the most spirited horses, are especially apt to get out of hand, and have almost everywhere suffered severely for it (*e. g.*, at Waterloo and Balaklava). The pursuit, on the rally being sounded, is generally left to some divisions or squadrons, especially or by general regulations designated for this service; while the mass of the troops re-form to be ready for all emergencies. For the disorganized state, even of the victors, after a charge, is inducement enough to always keep a reserve in hand which may be launched in case of failure in the first instance; and thus it is that the first rule in cavalry tactics has always

been, never to engage more than a portion of the disposable forces at a time. This general application of reserves will explain the variable nature of large cavalry combats, where the tide of victory ebbs and flows to and fro, either party being beaten in his turn until the last disposable reserves bring the power of their unbroken order to bear upon the disordered, surging mass, and decide the action. Another very important circumstance is the ground. No arm is so much controlled by the ground as cavalry. Heavy, deep soil will break the gallop into a slow canter; an obstacle which a single horseman would clear without looking at it, may break the order and solidity of the line; and an obstacle easy to clear for fresh horses will bring down animals that have been trotted and galloped about without food from early morning. Again, an unforeseen obstacle, by stopping the advance and entailing a change of front and formation, may bring the whole line within reach of the enemy's flank attacks. An example of how cavalry attacks should not be made was Murat's great charge at the battle of Leipsic. He formed 14,000 horsemen into one deep mass, and advanced on the Russian infantry which had just been repulsed in an attack on the village of Wachau. The French horse approached at a trot; about 600 or 800 yards from the allied infantry they broke into a canter; in the deep ground the horses soon got fatigued, and the impulse of the charge was spent by the time they reached the squares. Only a few battalions which had suffered severely were ridden over. Passing round the other squares, the mass galloped on through the second line of infantry, without doing any harm, and finally arrived at a line of ponds and morasses which put a stop to their progress. The horses were completely blown, the men in disorder, the regiments mixed and uncontrollable; in this state two Prussian regiments and the Cossacks of the guard, in all less than 2,000 men, surprised their flanks and drove them all pell mell back again. In this instance there was neither a reserve for unseen emergencies, nor any proper regard for pace and distance; the result was defeat.—The charge may be made in various formations. Tacticians distinguish the charge *en muraille*, when the squadrons of the charging line have none or but very small intervals between each other; the charge with intervals, where there are from 10 to 20 yards from squadron to squadron; the charge *en échelon*, where the successive squadrons break off one after the other from one wing, and thus reach the enemy not simultaneously but in succession, which form may be much strengthened by a squadron in open column on the outward rear of the squadron forming the first *échelon*; finally, the charge in column. This last is essentially opposed to the whole of the former modes of charging, which are all of them but modifications of the line attack. The line was the general and fundamental form of all cavalry charges up to Na-

poleon. In the whole of the 18th century we find cavalry charging in column in one case only, *i. e.*, when it had to break through a surrounding enemy. But Napoleon, whose cavalry was composed of brave men but bad riders, had to make up for the tactical imperfections of his mounted troops by some new contrivance. He began to send his cavalry to the charge in deep columns, thus forcing the front ranks to ride forward, and throwing at once a far greater number of horsemen upon the selected point of attack than could have been done by a line attack. The desire of acting with masses, during the campaigns succeeding that of 1807, became with Napoleon a sort of monomania. He invented formations of columns which were perfectly monstrous, and which, happening to be successful in 1809, were adhered to in the later campaigns, and helped to lose him many a battle. He formed columns of whole divisions either of infantry or of cavalry, by ranging deployed battalions and regiments one behind the other. This was first tried with cavalry at Eckmühl, in 1809, where ten regiments of cuirassiers charged in column, and two regiments deployed in front, four similar lines following at distances of about 60 yards. With infantry, columns of whole divisions, one battalion deployed behind the other, were formed at Wagram. Such manœuvres might not be dangerous against the slow and methodical Austrians of the time, but in every later campaign, and with more active enemies, they ended in defeat. We have seen what a pitiable end the great charge of Murat at Wachau, in the same formation, came to. The disastrous issue of D'Erlon's great infantry attack at Waterloo was caused by its being made with this formation. With cavalry the monster column appears especially faulty, as it absorbs the most valuable resources into one unwieldy mass, which, once launched, is irretrievably out of hand, and, whatever success it may have in front, is always at the mercy of smaller bodies well in hand that are thrown on its flanks. With the materials for one such column, a second line and one or two reserves might be prepared, the charges of which might not have such an effect at first, but would certainly by their repetition ultimately obtain greater results with smaller losses. In most services, indeed, this charge in column has either been abandoned, or it has been retained as a mere theoretical curiosity, while for all practical purposes the formation of large bodies of cavalry is made in several lines at charging intervals, supporting and relieving each other during a prolonged engagement. Napoleon, too, was the first to form his cavalry into masses of several divisions, called corps of cavalry. As a means of simplifying the transmission of commands in a large army, such an organization of the reserve cavalry is eminently necessary; but when maintained on the field of battle, when these corps had to act in a body, it never, except in the American civil war, produced any ade-

quate results. In the present European armies the cavalry corps is generally retained, and in the Prussian, Russian, and Austrian services there are even established normal formations and general rules for the action of such a corps on the field of battle, all of which are based on the formation of a first and second line and a reserve, together with indications for the placing of the horse artillery attached to such a body.—We have hitherto spoken of the action of cavalry so far only as it is directed against infantry. But one of the principal purposes for which this arm is used in battle, in fact its principal use at present, is its action against infantry. We have seen that in the 18th century infantry, in battle, scarcely ever formed square against cavalry. It received the charge in line, and if the attack was directed against a flank, a few companies wheeled back, *en potence*, to meet it. Frederick the Great instructed his infantry never to form square except when an isolated battalion was surprised by cavalry; and if in such a case it had formed square, "it may march straight against the enemy's horse, drive them away, and, never heeding their attacks, proceed to its destination." The thin lines of infantry in those days met the cavalry charge with full confidence in the effect of their fire, and indeed repelled it often enough; but where they once got broken, the disaster was irreparable, as at Hohenfriedberg and Zorndorf. At present, when the column has replaced the line in so many cases, the rule is that infantry always, where it is practicable, form square to receive cavalry. There are indeed many instances in modern wars where good cavalry has surprised infantry in line and had to fly from its fire; but they form the exception. The old question, whether cavalry has a fair chance of breaking squares of infantry, has lost a good deal of its importance, owing to the improvement in firearms and to the new tendency in the use of cavalry. It appears to be generally admitted that, under ordinary circumstances, a good, intact infantry, not shattered by artillery fire, stands a very great chance against cavalry; while with young foot soldiers, who have lost the edge of their energy and steadiness by a hard day's fighting, by heavy losses and long exposure to fire, a resolute cavalry has the best of it. There are exceptions, such as the charge of the German dragoons at Garcia Hernandez in 1812, where each of three squadrons broke an intact French square; but as a rule, a cavalry commander will not find it advisable to launch his men on such infantry. At Waterloo, Ney's grand charges with the mass of the French reserve cavalry on Wellington's centre could not break the English and German squares, because these troops, sheltered a good deal behind the crest of the ridge, had suffered very little from the preceding cannonade, and were almost all as good as intact. Such charges, therefore, are adapted for the last stage of a battle only, when the infantry has been a good deal shattered and

exhausted both by actual engagement and by passivity under a concentrated artillery fire; and in such cases they act decisively, as at Borodino and Ligny, especially when supported, as in both these cases, by infantry reserves.— We cannot enter here into the various duties which cavalry may be called upon to perform on outpost, patrolling, and escorting service, &c. A few words on the general tactics of cavalry, however, may find a place. Infantry having more and more become the main stay of battles, the manœuvres of the mounted arm are necessarily more or less subordinate to those of the former. And as modern tactics are founded upon the admixture and mutual support of the three arms, it follows that for at least a portion of the cavalry all independent action is entirely out of the question. Thus the cavalry of an army is always divided into two distinct bodies: divisional cavalry and reserve cavalry. The first consists of horsemen attached to the various divisions and corps of infantry, and under the same commander with them. In battle, its office is to seize any favorable moments which may offer themselves to gain an advantage, or to disengage its own infantry when attacked by superior forces. Its action is naturally limited, and its strength is not sufficient to act any way independently. The cavalry of reserve, the mass of the cavalry with the army, in European armies acts in the same subordinate position toward the whole infantry of the army as the divisional cavalry does toward the infantry division to which it belongs, but in America, as already shown, it is more independent. Accordingly, the reserve cavalry will be held in hand till a favorable moment for a great blow offers itself, either to repel a grand infantry or cavalry attack of the enemy, or to execute a charge of its own of a decisive nature. From what has been stated above, it will be evident that the proper use of the cavalry of reserve is generally during the latter stages of a great battle, or in an independent movement upon the rear or communications of the enemy. Such immense successes as Seydlitz obtained with his horse may not be expected hereafter; but still, many great battles of modern times have been very materially influenced by the part cavalry has played in them. But the great importance of cavalry lies in pursuit. Infantry supported by artillery need not despair against cavalry so long as it preserves its order and steadiness; but once broken, no matter by what cause, it is a prey to the mounted men that are launched against it. There is no running away from the horses; even on difficult ground, good horsemen can make their way; and an energetic pursuit of a beaten army by cavalry is always the best and the only way to secure the full fruits of the victory. Thus, whatever supremacy in battles may have been gained by infantry, cavalry still remains an indispensable arm, and will always remain so; and now, as heretofore, no army can enter the lists with a fair chance of suc-

cess unless it has a cavalry that can both ride and fight.

CAVAN. I. The southernmost county of the province of Ulster, Ireland, bounded by the counties Fermanagh, Monaghan, Meath, Westmeath, Longford, and Leitrim; area, 746 sq. m.; pop. in 1871, 140,555. The soil is wet and marshy, but with drainage it is rendered productive. The mountainous districts, which include a considerable part of the county, are barren. Coal, iron, lead, and copper are found; marl, fuller's earth, potter's and brick clays are plentiful. There are many mineral springs, of which that of Livalinbar is the most noted. Cavan was anciently called Breifne (Brenny), and was part of the territory of O'Rourke, the Irish chief, the seduction of whose wife by Dermot MacMurrough, king of Leinster, was the immediate cause of the English invasion. It was first made shire ground toward the close of the 16th century. The county was divided into baronies among the native possessors, five falling to the lot of the O'Reilly family. The O'Reillys having forfeited their possessions by rebellion at the beginning of the 17th century, Cavan reverted to the British crown. It now returns two members to parliament. II. The county town, on the Dublin and Galway railway, 85 m. N. E. of Galway, and 65 m. N. W. of Dublin; pop. about 3,000. Petty and quarter sessions, annual fairs, and a weekly market are held in the town. It contains a fine parish church, a Catholic chapel and nunnery, Presbyterian and Methodist meeting houses, a fever hospital, an infirmary, a royal endowed school, a barracks, and a public pleasure ground, bequeathed to the town by Lady Fernham.

CAVE, Edward, an English printer and bookseller, born at Newton, Warwickshire, Feb. 29, 1691, died in London, Jan. 10, 1754. He founded the "Gentleman's Magazine," the first number of which appeared in January, 1731, and which still continues to be published. The original purpose of this periodical, according to the prospectus, was to preserve from the newspapers "essays on various subjects for entertainment." Original communications, however, were afterward admitted, Dr. Johnson being a favorite contributor, and he wrote the "parliamentary speeches" which appeared in this magazine from 1740 to 1743. It has undergone many changes of management, but its special and most valuable features were always till recently antiquarian research and contemporary biography and history. The success of the magazine led to the establishment of the "London Magazine" and other rival publications of the same class, in which the "Gentleman's Magazine" was the pioneer. Cave was the early friend and patron of Dr. Johnson, and for a long time was his only publisher. Dr. Johnson was present at his deathbed, and he wrote the "Life of Cave" which was published in the "Gentleman's Magazine" for February, 1754. Cave had some claims to authorship, and wrote an "Account of Criminals."

CAVE, William, an English scholar and divine, born at Pickwell, Leicestershire, Dec. 30, 1637, died at Windsor, Aug. 4, 1713. He was educated at St. John's college, Cambridge, and became successively vicar of Islington, rector of Allhallows the Great, London, and chaplain to Charles II., who made him canon of Windsor. Having selected as his residence the quiet village of Isleworth, Middlesex, he devoted his life to researches into the history of the church. He produced a great number of works, the most important of which are his "Primitive Christianity" (1672), "Lives of the Apostles" (1675), and "Lives of the Fathers" (*Ecclesiastici*, 1682). His style is concise, simple, and easy, and his sentiments so liberal that he has been accused of Socinianism. A monument in Islington church marks his burial place.

CAVEAT (Lat. *cavere*, to beware), a formal notice or caution given by a party in interest to a court, judge, or public officer against the performance of certain acts, such as permitting a will to be proved, granting letters of administration, or patents for inventions, or for lands. Its object is to prevent any proceedings being taken without such notice to the party giving it as shall enable him to appear and show cause against the proposed action.

CAVEAU, a Parisian literary and convivial association, initiated in 1729 in the shop of the grocer Gallet, who was a witty songster and a friend of Crébillon the younger and other literary men. Subsequently the suspicion arose that Gallet was deriving too many pecuniary advantages from the habitués, and the place of meeting was removed to a tavern known as the Caveau (cave), whence the name. The dinners on the first Sunday of every month were attended by Helvétius and other celebrated persons. The association was discontinued toward the end of 1739.—Cappelle and Armand Gouffé established in 1806 the *Caveau moderne* in the café de Cancale, and the dinners, which took place on the 20th day of the month at the Rocher de Cancale, were presided over by Pierre Laujon, and after his death in 1811 by Désaugiers, most of whose songs were composed especially for these reunions. The latter invited Béranger, who was here first encouraged to publish his songs. After various vicissitudes the Caveau was reorganized in 1834 by Albert Montémont, at the Peste restaurant near the café de la Régence; and subsequently the monthly dinners took place in the café Corazza, in the palais royal, and Jules Janin was received as a member in 1866. At the present day the meetings are rather more ceremonious and academical than formerly.

CAVEDONE, Jacopo or Giacomo, an Italian painter, born at Sassuolo, Modena, in 1577, died in Bologna in 1660. Escaping from a home made unendurable to him by his father's violence, he became page to a nobleman in Bologna, whose picture gallery gave him an opportunity of cultivating artistic tastes, which were developed under the tuition of several masters, especially

Annibale Carracci, who soon ranked him among his ablest pupils. Subsequently he studied in Venice, and on his return to Bologna he executed pictures of the "Nativity" and the "Adoration of the Magi" for the San Paolo church, which gave him great reputation. His masterpiece in the church of the Mendicanti di Dentre, representing St. Alo and St. Petronio kneeling before the Virgin and child, with a glory of angels, is celebrated for the imposing and yet simple cast of the drapery, and for its matchless beauties of composition, coloring, and expression; it has been often ascribed, like many of his other productions, to his teacher Carracci, and to other illustrious masters. Guido took him as a model in fresco painting, in which he produced the finest and most harmonious effects by using a limited but the most suitable variety of tints. In richness of coloring he was unrivalled among the artists of the Bolognese school. The latter part of his life was saddened by charges of witchcraft brought against his wife by superstitious people, and by the death of an only son who was a promising artist. Distracted to the verge of madness and reduced to starvation by his inability to work, he fell senseless in the streets while unavailingly asking for alms, and was removed to a stable, where he soon breathed his last. Besides the pictures mentioned, most of his other works are in Bologna. Florence possesses his portrait painted by himself, Munich his "Dead Christ mourned by an Angel," and the Louvre in Paris his "St. Cecilia."

CAVEDONI, Celestino, an Italian archæologist and numismatist, born near Reggio, May 18, 1795, died in Modena, Nov. 26, 1865. He was educated in the episcopal seminary at Modena, studied archæology, Greek, and Hebrew at Bologna, became director of the numismatic collections of the library of Modena, and from 1830 to 1863 was professor of hermeneutics at the university. His principal works are *Nuismaticica Biblica* (Modena, 1850; German translation by Werlhof, 2 vols., Hanover, 1855-'6), and *Confutazione dei principali errori di Ernesto Renan nella sua Vie de Jésus* (Modena, 1863).

CAVELIER, Pierre Jules, a French sculptor, born in Paris, Aug. 30, 1814. He studied under Delaroche and David d'Angers, early obtained the grand prize, and was for some years supported in his studies at Rome by the French academy. He acquired celebrity in 1849 by his statue of Penelope, the medal of honor being conferred upon him, with a three years' pension of 4,000 francs. In 1865 he became a member of the institute. His works are remarkable for purity and grace. His statue representing "Truth" is in the Luxembourg; that of Abélard is in the new Louvre; and he has also made busts of Ary Scheffer, Horace Verdet, Napoleon I., and others.

CAVENDISH, Henry, an English philosopher, born at Nice, Oct. 10, 1731, died in London, Feb. 24, 1810. He was a man of great wealth

and of high attainments in chemistry and in general physics. He was the discoverer of the composition of water and of nitric acid, and proved that the electric spark will generate nitric acid from common air. He measured the density of the earth by direct comparison with balls of lead, and improved the modes of dividing astronomical instruments. He was the first chemical experimenter and discoverer in many important branches of that science. His writings may be found in the "Philosophical Transactions."

CAVENDISH, or **Candish**, Sir **Thomas**, an English adventurer of the 16th century. He was the son of a gentleman of good estate, residing at Trimley St. Martin in Suffolk; but having spent his patrimony, he engaged in a predatory excursion against the Spanish American colonies, fitting out three vessels of 120, 60, and 40 tons. This expedition started July 22, 1586, and entered the straits of Magellan Jan. 6, 1587. They were 33 days in clearing the straits, spending some time in examining the coast. On the Pacific coast they burnt Payta, Acapulco, and other towns, and finally captured the Spanish galleon *Santa Anna*, of 700 tons, loaded with a valuable cargo and 122,000 Spanish dollars. Cavendish then started from California, crossed the Pacific to the Ladrone islands, through the Indian archipelago and strait of Java, and around the Cape of Good Hope, reaching England Sept. 9, 1588, and was knighted by Queen Elizabeth. In August, 1591, he started again, but he experienced bad weather and sickness, his crew grew mutinous, and he died at sea in 1593.

CAVERY, or **Cauvery** (anc. *Chaleris*), a river of southern India, rises among the Coorg hills, near the W. or Malabar coast, 4,000 ft. above the level of the sea, in lat. 12° 25' N., lon. 75° 34' E. It flows in a circuitous course mainly S. E., traversing the whole breadth of the peninsula, and falls into the bay of Bengal, on the E. or Coromandel coast. In the vicinity of Trichinopoly it separates into several branches (the principal of which is the Coleroon river, 92 m. long), which descend in separate falls of 200 and 300 ft., and enter the sea by numerous mouths in the province of Tanjore. The whole course of the Cavery is about 470 m., and it is navigable only for small boats. The craft in use are circular baskets, from 9 to 14 ft. in diameter, covered with buffalo leather. In these produce is brought down the river, but as the violence of the stream makes upward navigation impossible, they are taken to pieces and the leather carried back on the heads of the crew.

CAVIANA, an island of Brazil, 35 m. long and 20 m. wide, in the N. mouth of the Amazon, under the equator. It is level, fertile, and well stocked with cattle. The small town of Roberdello is on its S. E. side.

CAVIARE, a kind of food prepared from the roes of large fish, especially the sturgeon. It is chiefly made in Russia, which country mo-

nopolizes this branch of commerce. From Astrakhan alone 30,000 bbls. have been exported in a single year. The process of manufacturing consists in thoroughly cleaning the roe from its membranes. Salt is then well mixed in, and the liquor pressed out. It is then dried and packed for sale. The best kind, that which is most thoroughly freed from the membrane, does not easily become fetid, and is packed in kegs; the inferior kind is made into small thin cakes. It is much used during seasons of fast in Italy, Russia, Greece, and Turkey, being eaten on bread with oil and vinegar or lemon.

CAVITE. **I.** A province of Luzon, Philippine islands, situated on the S. E. side of the bay of Manila; area, 489 sq. m.; pop. about 57,000. **II.** A town of the province, the naval depot of and the strongest place in the Spanish possessions in the East, 7 m. S. W. of Manila; pop. about 3,000. It is built on the E. extremity of a low bifurcated peninsula stretching about 3 m. into the sea, having between its extremities the outer harbor, while the inner harbor is S. of the town. Neither has more than four fathoms of water, though large ships moor near the inner harbor. The houses are two stories high, built chiefly of wood, the windows being furnished with semi-transparent shell instead of glass. It has two churches, three convents, an arsenal, magazine, and ship yard, and enjoys a considerable trade, but has declined of late years. During half the year it is the port of Manila.

CAVOUR, **Camillo Benso**, count, an Italian statesman, born in Turin, Aug. 10, 1810, died there, June 6, 1861. Being a younger son of a noble and wealthy family, he was destined for the army, entered the military academy at an early age, and in 1828 was appointed lieutenant of engineers, and stationed at Genoa. In 1831 he left the army because he disliked garrison life, and had moreover incurred the displeasure of King Charles Albert by speaking favorably of the French revolution of 1830. He retired to his estates, and devoted himself to their improvement, but still gave much attention to science and political economy. He made long visits to France and England, in order to study the industrial and political systems of those countries. Returning to Turin, he became attached to the reform party, and in 1842 was one of the founders of the *associazione agraria*, a semi-political society, and in 1847, in conjunction with Cesare Balbo, established the journal *Il Risorgimento* ("The Resurrection"), which became a powerful political organ. He was elected to the Sardinian parliament, and had much to do in inducing the king to grant the constitution of 1848, and to declare war against Austria. The campaigns both of 1848 and 1849 ended disastrously, and Charles Albert abdicated. In 1850 Cavour was called to the cabinet of Victor Emanuel as minister of commerce and agriculture. Soon after he became also minister of the marine and finance, and in 1852 was named president of

the council, in place of D'Azeglio. At this time what is now the kingdom of Italy was divided into several governments, having in all a population of about 25,000,000, and all overawed by the military power of Austria, which had reconquered Lombardy and Venetia, re-established the archducal and ducal authorities in Tuscany, Modena, and Parma, and occupied a portion of the papal territory by its troops. Though one of the smaller divisions in point of population, Sardinia was by far the most advanced in industry and national military force. All the energies of Cavour were now bent on preparing his state, which was slowly but steadily recovering from the shocks and humiliations suffered in 1848-'9, for the speedy resumption of the struggle with the Hapsburgs, with the object of uniting all Italy into one nation under the king of Sardinia. He obtained a European reputation by the course he took in opposing the pope and the ultramontanes at home, and in joining France, Great Britain, and Turkey against Russia in the Crimean war. In conjunction with the marquis Villamarina, he represented Sardinia in the peace conference held at Paris in the spring of 1856. During the sittings of this conference he succeeded in winning over Napoleon III. almost completely for his purposes, energetically protested against the continued occupation of the Pontifical States by foreign troops, and represented the necessity of inducing the king of Naples to moderate his system of government. He also carried through the Sardinian parliament the measure for suppressing convents and monasteries, and secularizing their estates, which drew down upon him, and all who participated in the enactment and execution of this statute, the major excommunication of the pope, and the hostility of a large portion of the Sardinian clergy and their supporters in parliament. Early in 1859 the contest between Austria and Sardinia broke out afresh, the latter counting upon the support of France. The Sardinian army was put upon a war footing; and on April 23 Austria demanded by an ultimatum that Sardinia should at once disarm. This was refused, and on the 27th the Austrians invaded Piedmont. The emperor Napoleon had promised to support Sardinia in case of invasion, and on May 3 he declared war against Austria. The victories of Magenta and Solferino put it in the power of the allies to dictate their own terms, and nothing less than the entire abandonment of Italy by the Austrians was looked for. The treaty of Villafranca, leaving Austria in possession of Venetia, and eventually involving the cession of Savoy and Nice to France, which Napoleon unexpectedly concluded with Francis Joseph, without consulting Victor Emanuel, disgusted Cavour. He resigned his post as prime minister, and was succeeded by Ratazzi, whose administration proved unsuccessful. In January, 1860, Cavour was again placed at the head of the government, with a ministry of his

own choice. He ostensibly opposed the movement of Garibaldi against Sicily and Naples, but soon secretly aided him with all means at his disposal; and Garibaldi, having been proclaimed dictator there, made over his authority to Victor Emanuel, and the people of the Two Sicilies accepted him as their sovereign. Gen. Cialdini, first operating in the north against Lamoricière, and then coöperating with Garibaldi, completed the work, with the aid of the Sardinian fleet under Persano. On Dec. 23, 1860, the decree appeared by which Sardinia (which had already absorbed Lombardy, Tuscany, Parma, and Modena) and the Two Sicilies, together with Umbria and the Marches, wrested from the pope, were united together as the kingdom of Italy, under the sceptre of Victor Emanuel. On Feb. 18, 1861, Cavour opened the first parliament of united Italy. Near the end of April there was a public avowal of the reconciliation between him and Garibaldi, who had reproached him, among other things, with supineness in resisting the encroachments of Napoleon. This was the last public act of Cavour. On May 30 he was attacked with a fever which ended his life. Cavour was one of the most enlightened, versatile, and energetic statesmen of the age; and though by several of his proceedings he incurred the bitter censures of D'Azeglio, Garibaldi, and Mazzini, it is now conceded on all hands that to him more than any other man is owing the achievement of the unity of Italy.— See Botta, "Life, Character, and Policy of Count Cavour" (New York, 1862), and Treitschke's brilliant essay, *Cavour*, in his *Historische und politische Aufsätze* (new series, Leipsic, 1870).

CAVY, a mammal of the order *rodentia*, family *histricidæ*, subfamily *caviina* (Waterhouse), and genera *dolichotis* and *cavia*. This subfamily is exclusively South American; the molar teeth are $\frac{4}{4}$, without roots, those of the upper jaw converging and nearly meeting in front, incisors short; four toes on the fore feet, and only three on the hind, and without clavicles. The cavies have been generally associated with the agoutis, and classed under the section *subungulata* of Illiger, erroneously in the opinion of Mr. Waterhouse, though the two groups approach each other in many respects. In some members of the subfamily, and probably in all, the fauces, or entrance to the throat, form a funnel-shaped cavity, opening backward into the pharynx by a small aperture capable of admitting only very finely chewed food; by the action of the muscles this conical cavity is made to pass over the epiglottis, preventing the entrance of the food into the windpipe; the stomach is simple, but the cæcum is large and complicated. The molar teeth of the upper jaw have the entering fold of enamel on the inner side, while in the lower it is on the outer side; the palatic portion of the skull in front of them is much contracted, and between them triangular, the posterior emargination being very deep, and exposing the anterior sphenoid bone;

in the lower jaw a well marked ridge extends along the outer side from the first molar, at first horizontally backward, but afterward curving upward to the condyloid portion, distinguishing them from all other rodents; the condyle is but little elevated above the crowns of the molars, and the coronoid process is extremely small, in this and other particulars resembling the tailless hares (*Lagomys*). The genus *dolichotis* (Desm.) is characterized by long limbs; ears half as long as the head, pointed, broad at the base; tail very short, and curved upward; metatarsus clothed with hairs anteriorly, posteriorly with the heel naked; molars small, the three front upper and the three posterior lower divided by folds of enamel into two equal lobes, the last upper and the front lower being three-lobed. The long legs, large ears, and distinct tail distinguish this from the genus *cavia*, of which the Guinea pig is a well known example. The cavies approach the hares in their comparatively short incisor teeth, the imperfect condition of the palate before alluded to, the narrow bodies of the sphenoid bones, and the small brain cavity; the skull, however, is not so large in its facial portion, and is more depressed, with much smaller incisive openings.—Uniting the two groups of the true cavies and the hares, comes the typical species of the genus *dolichotis*, the Patagonian cavy (*D. Patachonica*, Shaw). This animal is from 2½ to 3 ft. in length, about 13 inches high at the shoulders, weighing from 20 to 36 lbs. when full grown. It inhabits the desert and gravelly plains of Patagonia, from about lat. 48½° to 37½° S., on the Atlantic coast, and extending into La Plata as far as Mendoza, 33½° S. The fur is dense and crisp, gray on the upper parts of the head and body, yellowish rusty on the sides; chin, throat, and abdomen white; rump black, with a broad white band immediately

Patagonian Cavy (*Dolichotis Patachonica*).

above the tail; limbs rusty yellow, but grayish in front. It lives in burrows, but wanders occasionally to great distances from home in parties of two or three; it runs much

like the rabbit, though not very fast; it seldom squats like the hare, is very shy, and feeds by day; it produces two young at a birth, in its burrow; its flesh is white, but dry and tasteless. It has been generally mistaken by travellers for a hare, which it resembles in its legs, ears, and tail; the head is large, terminating in a blunt muzzle clothed with hairs; the upper lip is slightly notched; the mustaches are very long and black.—The genus *cavia* (Klein) is characterized by short limbs and ears, by feet naked beneath, and by molars nearly of equal size, each with two principal lobes. The genus presents two modifications of the molars: in one, the lobes are nearly equal, and the hinder lobe of the upper series has no distinct indenting fold of enamel; for this F. Cuvier has instituted the genus *cerodon*, which Waterhouse retains as a subgenus; in the other (containing the Guinea pig), the hinder lobe is the larger, and in the upper series has a deep indenting fold of enamel on the outer side, and the corresponding half of the lower molar with a deep fold on the inner side. The following species belong to the subgenus *cerodon*; those of *cavia* proper will be described under

Rock Cavy (*Cerodon rupestris*).

GUINEA FIG. The rock cavy (*C. rupestris*, Pr. Max.) inhabits the rocky districts of the interior of Brazil, in the higher parts of the river courses. The nails are short, obtuse, and projecting from large fleshy pads; the soft fur is of a grayish color, with a rufous tint on the back; lower parts white, with a pale ochreous-yellow tint on the abdomen; fore legs whitish with a rufous tinge, hind legs chestnut red behind. The length is about 14 inches, and it stands higher than most cavies. Its flesh is much esteemed by the Indians. The rufous-brown cavy (*C. flavidens*, Brandt) is somewhat larger than the Guinea pig, but its head, ears, and fur are shorter; the incisors are yellow; the color above inclines to a yellowish brown, below to yellowish white; it inhabits Brazil. Some of its varieties are of a rich rufous-brown color. Spix's cavy (*C. Spixii*, Wagler) inhabits Brazil from Rio de Janeiro to the Amazon; the general color is gray, with a tinge of brown on the back; the space between the eye and ear, a patch behind the ear, and the lower parts white; the incisors yellow. It is larger than the Guinea pig, with shorter and softer fur. The Bolivian cavy (*C. Boliviana*,

Waterh.) inhabits the elevated regions of Bolivia; the incisors are orange yellow; general color of the fur gray, with a faint yellow tinge; throat, abdomen, and feet whitish. It rarely exceeds 10 inches in length. Some of the lofty plains of the Andes are so undermined by the burrows of these animals, that every step of a horse is attended with danger. It is very shy. The southern cavy (*C. australis*, Is. Geoff.) is found in Patagonia from the straits of Magellan to lat. 39° S. The incisors are white; the fur soft and of a light grayish color; the eyes edged with white, and a spot of this color behind the ears. It is about 9 inches long, and is very tame; it lives in families, digging burrows in sandy hills overgrown with bushes; its food consists of seeds and green herbage, and it has been seen to ascend trees to feed on their fruits. It may be distinguished from all others of the group by the shortness of the head and the comparative length of the tarsi.—Numerous remains of fossil cavy have been found in the diluvial strata of Brazil; M. Lund has described four species from the caverns of that country.

CAWDOR, or **Calder**, a parish of Scotland, mostly in the county of Nairn, with a small section in Inverness; area, 4 sq. m. It contains Cawdor castle, built in the 15th century, in which tradition asserts that King Duncan was murdered by Macbeth, thane of Cawdor, as narrated by Shakespeare. The murder, however, took place in the 11th century. Lord Lovat lay long concealed in this castle after the rebellion of 1745.

CAWNPORE. I. A district of British India, in the Northwest Provinces, bounded N. E. by the Ganges, which separates it from Oude, and S. W. by the Jumna, which divides it from Bundelcund; area, 2,348 sq. m.; pop. in 1871, 1,152,628, mostly Hindoos. The chief productions are cotton, sugar, indigo, opium, safflower, wheat, barley, maize, pulse, tobacco, oil seeds, and potatoes. Schools are numerous. Good roads traverse the whole district, and the Ganges canal and great East Indian railway pass through it. It was ceded to the East India company in 1801 by the nawaub of Oude.

II. The principal town of the district, situated on the right bank of the Ganges, here about a mile wide, near the junction with the Ganges canal, and on the East Indian railway, 120 m. N. W. of Allahabad, 220 m. S. E. of Delhi, and 1,000 m. from Calcutta by river; pop. about 100,000, of whom half are distributed among the cantonments. It is poorly built, and has but one mosque of any pretension to elegance; but since its selection as a station for troops in 1777 it has acquired great commercial as well as military importance. The lines have accommodations for about 7,000 troops. The civilians, whose offices are in the native town, usually reside in the suburbs. There is here a Protestant church, and a free school, partly supported by a grant from the government, and attended by Hindoos, Mohammedans, and

Europeans.—While the rebellion was raging throughout Bengal in 1857, the military force at Cawnpore, commanded by Sir Hugh Wheeler, consisted of 3,800 men, of whom about 200 were Europeans. In June, apprehending a revolt, he threw up an intrenchment on the parade ground, enclosing two barrack hospitals and a few other buildings, into which he withdrew with about 900 Europeans, of whom two thirds were women, children, and other non-combatants. On the 5th the rising took place. The native regiments marched off, taking with them horses, arms, and ammunition, and setting fire to the bungalows on their way. They placed themselves under the leadership of the rajah of Bittoor, commonly known as the Nena Sahib, seized 35 boat loads of shot and shell on the canal, and the next day appeared before the intrenchment. The siege lasted until the 27th, when the Europeans, now reduced to less than half their original number, surrender-

Memorial Building on the Scene of the Massacre.

ed on promise of a safe passage to Allahabad. But no sooner had they embarked on the Ganges than they were fired upon from a masked battery. Many were killed in the boats, three or four made their escape, and the rest were captured and brought to land. The men were put to death; the women and children were kept alive till July 15, when the Nena, hearing of Gen. Havelock's advance toward Cawnpore, caused them to be massacred, and had their bodies thrown into a well. After defeating in three battles a strong native force sent out to oppose his march, Havelock entered the city July 18, while the Nena retreated to Bittoor. Memorial gardens have been laid out around the scene of the massacre, and a church erected; also, a fine octagon building around the well, without a roof, enclosing an elaborate tomb.

CAXAMARCA. See CAJAMARCA.

CAXATAMBO. See CAJATAMBO.

CAXIAS, an inland town of Brazil, on the navigable river Itapicuru, in the province and about 300 m. S. S. E. of Maranhão, and 1,230 m. N. of Rio de Janeiro. It is a large town, the centre of an important trade with the interior in cotton, rice, and cattle, which last are raised in large numbers in the surrounding country.

CAXIAS, Luis Alves de Lima, duke de, a Brazilian soldier and statesman, born in Rio de Janeiro about 1800. He entered the army while a boy, and rapidly rose to the ranks of general and baron, and subsequently to those of marshal, marquis, senator, and aide-de-camp of the emperor. He was twice a minister of war and also president of the council, exerting great political influence as a conservative leader. He defeated Rosas in 1851, and commanded against Lopez, 1866-'9. On account of ill health he was superseded by the count d'Eu after the capture of Asuncion, the emperor conferring upon him the title of duke.

CAXTON, William, the first English printer, born in Kent about 1412, died in 1491 or 1492. In his 15th or 16th year he was apprenticed to Robert Large, a London mercer, who became lord mayor in 1439. In 1441 Caxton became a freeman of the mercers' company, who appointed him their agent in the Low Countries, where he remained 23 years. In 1464 he was joined with Robert Whitehill in a commission to continue a treaty between Edward IV. of England and Philip, duke of Burgundy, or, if they thought it better, to make a new one. When the English princess Margaret of York married Charles of Burgundy, she took Caxton into her household. While in her service he translated from the French into English Raoul le Fèvre's *Recueil des histoires de Troye*. From the prologues and epilogues of this work it appears that he was acquainted with the art of printing, and from the character of his types it is evident that he learned it in the Low Countries. The first three printed works of Caxton were the original of Raoul's "History," the oration of John Russell on Charles, duke of Burgundy, being created a knight of the garter, and the translation of Raoul, the last completed in 1471. There is no certain evidence of the exact period of Caxton's return to England; the usual supposition dates it in 1474; it is beyond doubt, however, that in 1477 he had taken up his quarters in the vicinity of Westminster abbey, London. His printing office was in the Almonry, as appears from an old placard preserved at Oxford, which reads as follows: "If it plesse any man spirituel or temporal to bye any Pyes of two and thre comemoracions of Salisbury vse enprynted after the forme of this present lettre whiche ben wel and truly correct, late hym come to Westminster in to the Almonesye at the reed pale, and he shal have them good chepe." Caxton appears to have made use of several different sets of letters, the facsimiles of all which are to be found in Dibdin's account of Caxton's works. He had at first two kinds of the sort

called secretary; afterward he used three founts of great primer, a rude one employed in 1474, and two improved sets later; one fount of double pica, which first appears employed in 1490; and one of long primer. All his works were printed in black letter. Some entries in the parish accounts of St. Margaret, Westminster, in the year 1491 or 1492, are the only information we have of the date of his death: "Item; atte bureyng of William Caxton for iiij. torches vj. viij^d. Item; for the belle at same bureyng, vj^d." The largest collections of books from Caxton's press are those in the British museum, and in the library of Earl Spencer at Althorp. The names of about 64 productions are known. Warton says that by translating a great number of works from the French he did much in his day to enrich English literature.—See Lewis's "Life of Caxton" (London, 1737); "The Old Printer and the Modern Press," by Charles Knight (1854; new ed., 1861); and "Life and Typography of William Caxton," by William Blades (2 vols. 4to, London, 1861).

CAYCOS. See CAICOS.

CAYENNE, a fortified maritime city, capital of French Guiana, on the W. point of an island of the same name, at the mouth of the Oyak river; lat. 4° 56' N., lon. 52° 20' W.; pop. estimated at 5,700. Cayenne is a penal settlement, the seat of a court of assize and an apostolic prefecture, and the centre of all the trade of the province. It has two distinct divisions, the old and the new town; the former, with the government house and the Jesuits' college, is irregular, and the houses are indifferently built; while the streets of the latter are well laid out and paved, and kept in good order, and the dwellings neat, solid, and for the most part of pleasing appearance. The old and new towns are separated by the Place d'Armes, a spacious parallelogram fringed with orange trees. There are numerous warehouses, and but few public buildings worthy of mention. The port, one of the finest and most commodious on the coast, is protected by a fort commanding the town and several batteries; but it is too shallow to receive ships of much draft. It has convenient quays for loading and discharging vessels. The roadstead, though small, is unrivalled for beauty and convenience by any other on the W. shore of the South Atlantic.—The island, 32 m. in circumference, is separated from the mainland by a narrow channel; its surface is interspersed with small villages, inhabited chiefly by negroes (about 2,500). The principal products are sugar, molasses, cotton, coffee, and spices, which, with cacao, indigo, vanilla, and ebony, form the main exports. The climate is extremely unwholesome for Europeans, and large numbers of the convicts transported thither have been carried off on many occasions by yellow and other malignant fevers. During the first French revolution the practice began of exiling political offenders to Cayenne, the convention in 1795 decreeing the deporta-

tion of Billaud-Varenes, Collot d'Herbois, Barère, and 13 others. Many were sent there by Napoleon III.—Cayenne became a French colony about 1635. It was taken by the English, who held it from 1654 to 1664, when it was retaken by the French. It again fell into the hands of the British in 1667; was conquered by the Dutch in 1672, and recovered by the French in 1675; taken by the Portuguese and British in 1809, and finally restored in 1814.

CAYENNE PEPPER. See CAPSICUM.

CAYES, Aux. See AUX CAYES.

CAYLA, Zoé Victoire du, countess, a favorite of Louis XVIII., born at Boullay-Thierry, near Dreux, Aug. 5, 1785, died at Saint-Ouen, near Paris, March 19, 1852. She was the daughter of the royalist advocate Antoine Omer Talon (1760–1811) and the countess Pestré, and was educated under the direction of Madame Campan. She acquired celebrity by her beauty, grace, and accomplishments, and married in 1802 M. de Baschi, count du Cayla, who died in 1851. The union was unhappy, and they were formally separated after a protracted litigation. In 1807 she obtained the release of her father, who had been sentenced to transportation in 1804 as an agent of the Bourbon princes. After the restoration she gained considerable influence over Louis XVIII., though the relation was, according to most authorities, purely platonic. The clerical party turned her influence to account in furthering their designs. Lafayette asserts in his memoirs that, at the king's request, she destroyed papers relating to an important lawsuit in which her father had been engaged as one of the Bourbon advocates. The aged monarch endowed her with a fine palace at Saint-Ouen, and lavished other gifts and favors upon her; and she was believed to have increased her wealth by receiving bribes for securing appointments to public offices. After her patron's death in 1824 she became chiefly known by industrial and agricultural enterprises. She founded the Savonnerie, a carpet manufactory (originally one of soap), which in 1826 was transferred to the Gobelins. Mehemet Ali having presented her with a long-haired Nubian ram, she raised by crossing with English sheep a new breed of these animals, to which her name has been given.

CAYLEY, Arthur, an English mathematician, born at Richmond in 1821. He was educated at King's college, London, and afterward at Trinity college, Cambridge. He was called to the bar at Lincoln's Inn in 1849, and subsequently practised as a conveyancer till 1863, when he was called to the newly instituted Sadlerian professorship of pure mathematics in Cambridge university, which post he still occupies (1873). He is a fellow of the royal society, and correspondent of the French institute for the section of astronomy. He has contributed numerous valuable papers to the "Philosophical Transactions" and other scientific publications.

CAYLEY, Sir George, an English philosopher, born at Brompton, Yorkshire, in 1773, died Dec. 15, 1857. He undertook the analysis of the mechanical properties of air under chemical and physical action, and his papers on the subject gave rise to many experiments on the navigation of balloons. His experiments on the steam engine led to his invention of the air engine. His discoveries in optics were followed by the invention of an instrument for testing the purity of water by the abstraction of light. He was also the inventor of an ingenious arrangement for obtaining and applying electric power to machinery. He was one of the original promoters of the polytechnic institution at London. Toward the end of the last century he applied to his extensive estates in Yorkshire a new system of arterial drainage. He was also the father of the cottage allotment system. As a politician, he took a prominent part in the election of liberal members of parliament. Upon the passing of the reform bill he was himself chosen member for Scarborough, but on account of age he soon retired.

CAYLUS, or Caylux, a town of France, department of Tarn-et-Garonne, on the river Bonnette, an affluent of the Aveyron, 26 m. N. E. of Montauban; pop. in 1866, 4,950. It has an active trade in agricultural products, and contains the ruins of a fortified castle.

CAYLUS. I. Marthe Marguerite de Villette de Murcay, marquise de, a French woman of fashion, born in Poitou in 1673, died April 25, 1729. A descendant of D'Aubigné, she was converted to Roman Catholicism by her relative Mme. de Maintenon, and acquired celebrity as one of the brilliant wits and social leaders of the French court. Of a precocious beauty, she married in 1686 the marquis de Caylus, a drunkard, who died in November, 1704. Racine, delighted with her histrionic genius, wrote for her the prologue to his tragedy of *Esther*. Her fondness for raillery caused her banishment from the court. Her unhappy marriage led her on her return to accept the duke of Villeroi as her lover. Voltaire remarked that she could not have chosen better, but Mme. de Maintenon, whom she humorously called Nero, had her once more sent out of the capital. She came back in February, 1707, and after Mme. de Maintenon's death in 1719 her lover resided permanently at her house. Her famous *Souvenirs* were edited with notes and a preface by Voltaire (1770; new eds., 1804 and 1806), who regarded them as masterpieces of candor and wit; and Sainte-Beuve assigned to her a distinguished place in his *Galerie des femmes célèbres* (1858). **II. Anne Claude Philippe de Tubières,** count, a French archæologist, son of the preceding, born in Paris, Oct. 31, 1692, died Sept. 5, 1765. He early entered the military service, and distinguished himself in the war of the Spanish succession. He then devoted himself to literary pursuits and to travel, and published the results of his studies and researches in *Recueil d'antiquités égyptiennes, étrusques,*

grecques, romaines et gauloises (7 vols. 4to). The last volume appeared in 1767, two years after his death. He wrote also several shorter works on art and antiquities, and a number of novels of no great merit. In 1805 appeared the *Souvenirs du comte de Caylus* (2 vols. 12mo).

CAYMAN. See ALLIGATOR.

CAYMANS, three small islands of the British West Indies, in the Caribbean sea, forming a dependency of Jamaica. They are low islands of coral formation, and two of them are barren and uninhabited. Grand Cayman, the largest, is 24 m. long by 2½ broad, is covered with cocoanut trees, and has an anchorage on the S. W. side; pop. about 1,600. The inhabitants are bold sailors, and much employed as pilots. They also catch large numbers of turtles on their shore, to supply the markets of Jamaica.

CAYUGA, a central county of New York, bounded N. by Lake Ontario, W. by Cayuga lake, touching Skaneateles lake on the E., and traversed by the Seneca river and other smaller streams, which furnish abundant water power; area, about 752 sq. m.; pop. in 1870, 59,550. The surface is undulating, the soil fertile; salt, gypsum, and limestone abound. Owasco lake, 10 m. long, lies in its centre. The Southern Central, the New York Central, and Auburn branch railroads traverse it. The chief productions in 1870 were 622,237 bushels of wheat, 703,148 of Indian corn, 916,168 of oats, 732,140 of barley, 397,747 of potatoes, 87,604 tons of hay, 2,392,238 lbs. of butter, 324,792 of wool, and 96,287 of tobacco. There were 14,453 horses, 21,332 milch cows, 14,256 other cattle, 53,915 sheep, and 14,929 swine. There were 13 manufactories of agricultural implements, 5 of boots and shoes, 1 of carpets, 31 of carriages and wagons, 2 of planes, 24 flour mills, 27 saw mills, 6 manufactories of woollen goods, 13 of iron, 10 brick kilns, 2 manufactories of files, 7 of furniture, 2 of hardware, 1 of saddlers' tools, 11 of ground plaster, 15 of tin, copper, and sheet-iron ware, and 7 of tobacco and cigars. Capital, Auburn.

CAYUGA LAKE, in the central part of New York, separates Cayuga from Seneca county, and extends S. into Tompkins county. It is about 38 m. long, and from 1 to 3½ m. wide, and is navigable in all parts, but for about 6 m. from its N. extremity it is comparatively shallow. On advancing S. it becomes much deeper, and in some places is said to be unfathomable. It is rarely frozen over, except at the shallow portion. Its surface is 146 ft. above Lake Ontario, and 377 ft. above the sea. Its outlet is Seneca river on the north, which connects it with Seneca and Oneida lakes.

CAYUGAS, one of the tribes of the Hotinonsi-omni or Iroquois, commonly known as the Six Nations. They called themselves Goiogwen or Gweugwen. They inhabited three or four villages in a pleasant district on Cayuga lake. They numbered when first known to the French about 300 warriors, and comprised the three families common to all, Turtle, Bear, and Wolf,

and also the Beaver with the Deer, Snipe, Hawk, and Heron. They gave ten hereditary sachems to the league. As early as 1656 the French, by their missionaries Chaumonot and Menard, attempted to win them over; but though these missions were renewed and continued by Carheil down to 1684, they made little impression on the tribe, which took part in all the wars against the French. In 1667 a part of the tribe, hard pressed by the Susquehannas, crossed over to Quinté bay. Among the great chiefs of the tribe were Sa-onchiogwa, who became a Christian in 1671, and Ourcouhare or Tawerahet, who was taken and sent to the galleys in France, but on his return became a firm friend of the French. During the American revolution they joined the English, having already been in arms against the colonists at Point Pleasant in 1774. They greatly annoyed Gen. Clinton in his march to cooperate with Sullivan in 1779, and soon saw their villages destroyed. After the war they ceded all their land to the state of New York except a small reservation, which they abandoned in 1800. Some joined the Senecas, some went to Grand river in Canada, and others to Sandusky, whence they were removed to the Indian territory. They have now dwindled to about 250.

CAYX, Remi Jean Baptiste Charles, a French historian, born at Cahors in 1795, died in Paris in 1858. He studied in Paris, and became in 1850 rector of the academy of the department of the Seine, after having occupied other important positions as teacher and librarian, and from 1840 to 1845 a seat in the chamber of deputies. His *Récits d'histoire ancienne* (1823) and his *Histoire de France pendant le moyen âge* (1835) passed through many editions; and his other writings include *Histoire de l'empire romain* (2 vols., 1828).

CAZALLA DE LA SIERRA, a town of Andalusia, Spain, in the province and 40 m. N. E. of Seville; pop. about 6,500. It contains numerous religious edifices, ruined villas, and Roman and Arabic antiquities.

CAZEMBE, a negro state in the interior of S. E. Africa, so called from the title of its sovereign. It is situated S. of Lake Tanganyika and E. of Muroque, but its boundaries are not precisely known. Recent travellers estimate the area at 120,000 sq. m., and the population at 500,000. The western part of the country consists of elevated plains. The most important river is the Luapula. The chief articles of trade are slaves, ivory, salt, and copper. The Cazembe resides in Lunda or Lucenda, a large town situated upon Lake Moero, lat. 9° 30' S., lon. 29° 16' E. The country was visited in 1831 by Gamito de Tete, a Portuguese. An account of his travels was published at Lisbon in 1854. Livingstone visited the country in 1867.

CAZENOVIA, a town and village on a small lake of the same name in Madison co., New York; pop. of the town in 1870, 4,265; of the village, 1,718. It is the seat of a Methodist

seminary, which in 1871 had 12 instructors, 555 pupils, and a library of 2,500 volumes.

CAZORLA, a town of Andalusia, Spain, on the Vega, in the province and 44 m. E. N. E. of Jaen; pop. about 5,000. It is well built, in the form of an amphitheatre, on the sides of a mountain valley, and contains two spacious squares, one of which is adorned with a fine central fountain. It is defended by two old castles, one of them of Moorish origin, and has in its environs many gardens and public walks. Cazorla figured conspicuously in the Moorish contests of the 13th century. After repeated attempts it was taken and partly burned by the French in 1811.

CAZOTTE, Jacques, a French writer, born at Dijon in 1720, guillotined in Paris, Sept. 25, 1792. He became first known by a prose poem, *Olivier*, somewhat in the style of Ariosto's poems. Soon a number of tales, full of wit and originality, among them *Le diable amoureux* and *Le lord impromptu*, added to his fame. He was endowed with such facility and power of imitation that in one night he wrote a sequel to Voltaire's poem, *La guerre civile de Genève*, and so perfect was the imitation that no one doubted the addition to be Voltaire's own. Cazotte in his later years became one of the most fervent adepts of Illuminism and Martinism. Being a faithful royalist, he was arrested during the revolution, and escaped death in the September massacres through the heroism and entreaties of his daughter Elisabeth, but was soon arrested again, condemned by a tribunal, and executed.

CEAN-BERMEDEZ, Juan Agustin, a Spanish archeologist, born at Gijon, in Asturias, Sept. 17, 1749, died in Madrid, Dec. 3, 1829. He devoted himself early to the study of the fine arts, into which he was initiated by Raphael Mengs. After holding a public office at Madrid, he retired to Seville, where he founded an academy of fine arts, and occupied himself with the study of their history. He was elected a member of the royal academies of history and fine arts at Madrid, and published several valuable works connected with his favorite pursuits, including a *Diccionario histórico de las mas ilustres profesoras de las bellas artes en España* (6 vols., Madrid, 1800), and *Noticias de los arquitectos y arquitectura de España* (4 vols., 1829). His most important book, entitled *Sumario de las antigüedades romanas que hay en España*, appeared posthumously in 1832.

CEARÁ, a maritime province of Brazil, bounded N. by the Atlantic ocean, E. by the provinces of Rio Grande do Norte and Parahyba, S. by Pernambuco and W. by Piahy; area, 42,634 sq. m.; pop. about 550,000. The province is divided into two portions by a line of mountains running from the coast, near the capital, S. S. W. to the Serra de Ibiapaba, a narrow range of highlands bordering the W. portion of the province. The S. E. half forms a single basin watered by the Jaguaribe, the most important river in the province, and its affluents;

and the W. half is drained by a host of small rivers all flowing directly into the sea. The coast line is one vast sandy belt of inconsiderable elevation, varying in width from 12 to 18 m.; and the lands beyond, though so low and flat as to remind one of the pampas of the Argentine Republic, are very fertile. Still further westward the face of the country gradually rises toward the mountains, the whole region adjacent to which is made extremely fertile by innumerable springs forming small streams. The climate, moist and tempered by refreshing sea breezes on the coast, is in the interior very hot and dry, although the temperature never rises above 95° F., nor descends below 64°. The rainy season begins about February and lasts till June; the remainder of the year being without rain, all the running streams and rivers dry up, and the want of water is such at times as to oblige the inhabitants to abandon their homes. Among the more important natural productions are quina, ipecacuanha, tatajuba, mahogany, cedar, pao d'arco, carnahuba, and numberless other species of timber and woods valuable for building, dyeing, &c. The caoutchouc tree (*corypha cerifera*, Martins) is so abundant in some parts that Gardner says he "rode for about two days through a forest of almost nothing else. Cotton, coffee, sugar cane, mandioca, maize, rice, some wheat, and other cereals are cultivated; and most varieties of intertropical fruits are exceedingly abundant. The exports consist mainly of cotton, sugar, hides, India rubber, coffee, horns and bones, horse and cow hair, carnahuba wax and half-tanned hides. Ceará has about 100,000 horses and 600,000 head of horned cattle, and considerable cheese is made; but large quantities of butter, cheese, and lard are imported. Much has been done by government to improve the communication with the interior, and a railway from the capital to the great coffee district called Serra de Baturité is now (1873) in process of construction. The mineral productions are amethysts, gypsum, saltpetre, salt, alum, magnesia, carbonate of potassium, amianthus, lignite, gold, copper, zinc, galena, and graphite. Bones, and even perfect skeletons of huge mastodons, megatheria, and other mammals, are abundant in many parts. The capital is Portaleza, and there are seven other small cities.

CEBES, a Greek philosopher, lived in the 5th century B. C. at Thebes in Bœotia. He was a disciple of Socrates, and is introduced by Plato as one of the interlocutors in his "Phædo." He was the author of three dialogues, "The Seventh" (*Ἑβδόμη*), "Phrynichus," and "The Picture" (*Πίναξ*), of which the last only is extant. It presents a picture of human life in the form of a philosophical allegory, and has been translated into almost all the modern languages, even into Arabic. The best editions are those of Schweighäuser (Strasburg, 1806) and of Coraes, in his edition of Epictetus (Paris, 1826).

CEBÚ, or **Zebú**. **I.** An island in the Philippine archipelago, between Bohol and Negros, and between lat. $9^{\circ} 35'$ and 11° N., and lon. 123° and $123^{\circ} 50'$ E. It is a narrow strip of land, stretching N. N. E. and S. S. W.; area, about 2,200 sq. m. It is of uneven surface and stony soil, little suited to agriculture, though there are some valleys of remarkable fertility, yielding cotton, sugar, rice, millet, tobacco, and cacao, the last of which is far superior to that of all the other Philippines. The climate, spite of its excessive heat, which is tempered by alternate land and sea breezes, is delightful and very salubrious. Magalhaens discovered the island in 1521, and induced or constrained the people to embrace Christianity; but he was murdered on the adjacent island of Mactan in the same year. In 1565 Legarpi, the first Spanish governor, resorted to coercive measures to reclaim the apostate natives, who after the death of Magalhaens had relapsed into idolatry; but their final and lasting conversion is due to the disinterested zeal and untiring efforts of Urdaneta, a Spanish priest. **II.** A town on the above island, capital of a province of the same name, comprising the islands of Cebú, Bohol, Mactan, Batayan, Sicjor, and Camotos, situated on the eastern shore of the island of Mactan. The houses are well built of stone, and are in general handsome and spacious. The most noteworthy among the public edifices are the cathedral and the episcopal palace, both of elegant exterior; and there are besides a hospital for lepers and some school houses. The inhabitants comprise three races: the pure-blooded natives, mostly of the Bisayan race, with a few Tagals, though these are mostly confined to Luzon; Europeans; and mestizos descended from the early Spanish settlers and the native women. The mestizos, though extremely industrious, at the head of the commercial interests, and by far the wealthiest class of the three, are yet constrained to live entirely by themselves; and one half of the town, which is pretty equally divided by a stream or small river, is exclusively occupied by these half-castes, who are held in utter aversion by the pure-blooded races, foreigners as well as natives. Cebú is the seat of a bishopric, which has under its jurisdiction 13 of the 35 provinces comprising the Spanish Philippines, and of the civil and military authorities of the province. The town carries on a considerable trade, chiefly with Manila.

CECCO D'ASCOLI, an Italian savant and martyr, whose real name was FRANCESCO (of which Cecco is a diminutive) STABILI, born at Ascoli in 1257, died in Florence, Sept. 16, 1327. He taught astrology, philosophy, and mathematics, and to escape from penalties imposed upon him by the inquisition for his alleged heterodoxy, he went in December, 1324, to Florence, where however he was handed over to the secular courts as a heretic and sentenced to die at the stake. It has been asserted that he had been for some time physician to Pope John

XXII.; that from having been a friend of Dante he became an adverse critic of his writings and of those of Guido Cavalcante; and that the admirers of the illustrious poet joined the inquisitors who clamored for his death. But there is no conclusive authority for these and other statements in regard to him, excepting in respect to the circumstances attending his death. He possessed an extraordinary amount of information for his day, as attested by his principal work, *L'Acerba*, a kind of poetic cyclopædia, in four parts, devoted to the sciences and to ethics, and finished only to the beginning of the fifth part, which he had reserved for theology. His writings were chiefly founded upon personal observations and experiments, and foreshadowed even the principle of the circulation of the blood. The work passed through 20 editions from the time of its first appearance (about 1473) to about 1523, the least imperfect being that of Venice, 1510.

CECIL, a N. E. county of Maryland, bordering on Pennsylvania and Delaware, and situated at the head of Chesapeake bay, which forms its S. W. boundary; area, about 300 sq. m.; pop. in 1870, 25,874, of whom 4,014 were colored. Several bays indent it. Its W. border is washed by the Susquehanna, and Sassafras river bounds it on the south. The surface is slightly uneven and the soil fertile. At Port Deposit are immense granite quarries, and the county also contains gneiss, slate, iron, chrome, and sulphate of magnesia. It is intersected by the Philadelphia, Wilmington, and Baltimore, the Port Deposit branch, and the Philadelphia and Baltimore Central railroads. The chief productions in 1870 were 365,818 bushels of wheat, 683,683 of Indian corn, 305,307 of oats, 110,839 of potatoes, 19,986 tons of hay, 445,720 lbs. of butter, and 14,102 of wool. There were 4,824 horses, 5,797 milch cows, 7,471 other cattle, 4,579 sheep, and 9,716 swine. There were 21 flour mills, 1 manufactory of cotton goods, 7 of iron, 4 of paper, 2 of sashes, doors, and blinds, 5 saw mills, and 4 manufactories of woollen goods. Capital, Elkton.

CECIL, Robert, earl of Salisbury, an English statesman, son of Lord Burleigh by Mildred, his second wife, born about the middle of the 16th century, died at Marlborough, May 24, 1612. He was of weakly constitution and deformed in person, but gifted with great acuteness and energy. On his election to parliament as member for Westminster, his abilities attracted the notice of Queen Elizabeth, who attached him to the French mission, and subsequently appointed him assistant secretary of state. The earl of Essex was at this time the queen's favorite. His influence and that of the Cecils, father and son, continually came into collision; consequently a rivalry sprung up between them, which continued, openly or secretly, until Essex perished on the block. In 1590 Secretary Walsingham died. Essex demanded the office for a nominee of his own, while Burleigh requested it for his son Robert.

The queen, unwilling to offend her favorite, left the appointment open, and Cecil was not installed as principal secretary of state till 1596. While Essex was absent on the second Spanish expedition, Cecil contrived to procure for himself the chancellorship of the duchy of Lancaster, which the earl had requested for a friend. That quarrel was however made up, and Cecil, being sent to France, much against his will, to negotiate a peace between Henry IV. and the Spaniards, deemed it an effectual way of tying his rival's hands to confide the secretaryship to him during his own absence. Essex discharged the trust honorably. Cecil's first act on his return was to thwart Essex in his attempt to obtain the deputyship of Ireland for Sir George Carew, an incident which brought about the celebrated quarrel in which Elizabeth boxed her favorite's ears and told him to "go to the devil." Essex's fall was rapid, and Secretary Cecil was soon relieved from his rivalry. He is accused of having in like manner sacrificed Sir Walter Raleigh, while professing to be his friend. On the death of his father he was made premier. Elizabeth placed confidence in his great ability, and he was at all times ready in appearance to sacrifice his own views to the "divine judgment of his sovereign." Yet in reality he endeavored with success, both in Elizabeth's reign and that of her successor, to restrain the power of the crown. Having secretly favored the interests of James I., he was rewarded by that sovereign on his accession by being continued in office, and by being created in 1603 baron of Essendine, in 1604 Viscount Cranborne, and in 1605 earl of Salisbury. In 1608 he succeeded Dorset as lord high treasurer, notwithstanding the exertions of his new rival, but former friend, Henry Howard, earl of Northampton, to obtain the office. When the gunpowder plot was found to be no fiction, he entered actively into the detection of the conspirators. A work of his is extant, entitled "A Treatise against Papists." James had the highest opinion of his sagacity in discovering plots, and called him on that account by the familiar appellation of "my little beagle." He could not be brought, however, to assent to James's project for the incorporation of the two kingdoms. In all other matters the king followed his lead, asking nothing in return but money to carry on his extravagant expenditure. Thus the whole cares of the government were thrown on his shoulders. James had no order in his expenditure. The ordinary revenues being insufficient to meet his wants, imposts were laid on articles of commerce by proclamation. The country denied the constitutionality of this proceeding, but the court of exchequer decided in favor of the king. Cecil interposed between the king and the people. He asked, in conference of the two houses of parliament, that an immediate subsidy should be voted to liquidate the royal debt, and that an addition of £200,000 be made to the annual

income, to prevent the recurrence of a similar exercise of the king's prerogative. Parliament retorted on the king by a demand for numerous reforms. After protracted conferences, both houses adjourned without granting the required supplies. The failure of his proposition was a source of bitter mortification to the treasurer. His health sank under a complication of disorders. Having tried the mineral waters of Bath without benefit, he set out for London, but died on the way. Lord Hailes published "Secret Correspondence of Sir Robert Cecil with James VI. of Scotland" (12mo, 1766).

CECIL, William. See BURLEIGH, LORD.

CECILIA, Saint, a Roman lady of high descent, born about the middle of the 2d or the commencement of the 3d century. Compelled by her parents to marry Valerian, a noble youth of Rome, although she had at an early age made a vow to consecrate her life to religion, she was eventually doomed to suffer martyrdom; and her husband, her brother-in-law, and another Roman, whom she is believed to have converted, were supposed to have met with the same fate. St. Cecilia is the chosen patroness of musicians, and from her skill in singing is especially regarded as the patroness of sacred music. St. Cecilia's day, Nov. 22, is annually celebrated in England by a musical festival. Several churches were built in her honor at Rome. Beautiful pictures of the saint were executed by Raphael and other celebrated painters, and Père de Brailion of the Oratoire published in 1668 a work entitled, *La sépulture admirable de Sainte Cécile dans son église de Rome.*

CECROPS, first king of Attica, said to have reigned about 1550 B. C., and represented in the ancient legends as the civilizer of that country. He founded Cecropia, which at a later period became the Acropolis of Athens, and several other places; divided Attica into 12 communities; taught its inhabitants morality and manners, marriage, and the worship of the gods; abolished bloody sacrifices, and introduced agriculture, navigation, ship building, and the culture of the olive. According to some he was of Pelasgian origin, while others say he was the leader of an Egyptian colony from Sais. He reigned 50 years. His merits were commemorated by a monument in the temple of Minerva, in favor of which goddess he is said to have decided a dispute with Neptune concerning the possession of Attica. He was also worshipped in the constellation of Aquarius. In sculpture he was represented as half man half woman, or half man half serpent; hence he is sometimes styled *διφύης*, twofold.

CEDAR, the name of several species of evergreen trees of the order *coniferae*, the principal of which are the cedar of Lebanon (*pinus cedrus*, Linn.), the cedar of Goa (*cupressus Lusitanica*, Linn.), the Indian cedar (*pinus deodara*, Lambert), the white cedar (*cupressus thyoides*, Linn.), and the red cedar (*juniperus Virginiana*,

Linn.).—The cedar of Lebanon, or cedar larch, is a native of the coldest parts of Mt. Lebanon and the range of the Taurus, and from its superior magnificence became with Scripture

counted here 28 cedars; Rauwolf, in 1574, found 24, and two others the branches of which were decayed through age; De la Roque, in 1588, found 20; Maundrell, in 1696,

Cedars of Lebanon.

writers a favorite emblem for greatness, splendor, and majesty. The durability and fragrance of its wood caused it to be sought for costly buildings, as the palace of David and the temple of Solomon. Though it formerly covered

16; Pococke, about 1740, counted only 15. Graham measured 12 trees whose circumference was from 22 to 40 ft., the largest trees having a diameter of about 16 ft. Around these there is a grove of several hundred smaller trees, apparently of a different species of cedar. Seetzen, Ehrenberg, Berggren, and Bové have described other groves. Henry H. Jessup, an American missionary in Syria, in 1867 described eleven distinct groves of cedars, five

in northern and six in southern Lebanon.—The cedar of Goa is found wild in parts of India and Japan, and has been naturalized in Portugal around Cintra. It is the handsomest tree of the genus *cupressus*, and distinguished by its abundance of long dichotomous pendent branchlets.—The Indian cedar is a large tree found wild on the mountains of Nepal and Thibet, at a height of about 10,000 ft. above the sea. Its timber possesses the qualities attributed by the ancients to the cedar of Lebanon, being compact, resinous, and fragrant. It is much used for building in India, and has been introduced into

Cones of Cedar of Lebanon.

Lebanon with dense forests, so that fourscore thousand hewers were employed by Solomon in obtaining timber from them, yet the destruction of the trees for architectural purposes was more rapid than their growth, and in the 6th century Justinian found it difficult to procure cedar timber enough for the roof of a single church. At present they appear to be confined to a few localities, the most frequently visited among them being a valley in the Lebanon range, about 15 m. from the sea, at an elevation of 6,000 ft. Belon, in 1550,

Red Cedar.

England as an ornamental tree.—The white cedar is an abundant tree in swamps in the United States southward from Massachusetts and Ohio, reaching a height of from 30 to 70

ft. It has a fibrous, shreddy bark; leaves of a dull, glaucous-green color, very small and scale-like; and an exceedingly durable wood of a reddish color. Every part of the tree is strong-scented. It is used as a material for fences, and is in the highest esteem for shingles and coopers' staves.—The red cedar is a native of North America, the West Indies, and also Japan, and attains a height of from 15 to 30 ft. Its wood is odorless, of a bright red color, very compact and durable, and offensive to most insects. It is much used for the purposes of the cabinetmaker and for the outsides of black-lead pencils.—In California several varieties of the cedar attain an immense size.

CEDAR. I. An E. county of Iowa, intersected by Cedar and Wapsipicon rivers; area, 576 sq. m.; pop. in 1870, 19,731. Cedar river, from which the county is named, flows through a narrow pass in the W. part, on either side of which its rocky banks rise perpendicularly to a great height. The surface is diversified by fertile undulating prairies and woodlands. The S. W. corner is touched by the Chicago, Rock Island, and Pacific railroad, and the Chicago and Northwestern railroad passes through it. The chief productions in 1870 were 632,878 bushels of wheat, 2,203,802 of Indian corn, 723,312 of oats, 141,182 of barley, 92,937 of potatoes, 20,916 of flax-seed, 38,820 tons of hay, 28,656 lbs. of cheese, 741,650 of butter, and 35,087 of wool. There were 8,553 horses, 9,194 milch cows, 15,403 other cattle, 7,481 sheep, and 31,898 swine. There were 8 manufactories of carriages and wagons and 6 of saddlery and harness. Capital, Tipton. II. A N. E. county of Nebraska, separated from Dakota on the N. E. by the Missouri river, and watered by its affluents and those of the Elkhorn; area, 650 sq. m.; pop. in 1870, 1,032. The surface is diversified, the soil fertile. The chief productions in 1870 were 24,555 bushels of wheat, 16,900 of Indian corn, 11,875 of oats, 12,190 of potatoes, and 3,214 tons of hay. There were 224 horses, 557 milch cows, 1,324 other cattle, and 752 swine. Capital, St. James. III. A S. W. county of Missouri, intersected by Sac river; area, 435 sq. m.; pop. in 1870, 9,474, of whom 111 were colored. Its surface is uneven, the soil productive. A railroad connects it with Fort Scott, Kansas, and with the Atlantic and Pacific railroad at Lebanon. The chief productions in 1870 were 59,377 bushels of wheat, 326,060 of Indian corn, 49,588 of oats, 17,070 of potatoes, 1,102 tons of hay, and 37,465 lbs. of tobacco. There were 3,089 horses, 2,347 milch cows, 5,680 other cattle, 7,750 sheep, and 11,774 swine. Capital, Stockton.

CEDAR BIRD (*bombycilla cedrorum*, Vieill.; *ampelis cedrorum*, Baird), a bird of the waxwing family, smaller, more southern, and less migratory than the *A. garrulus*, Linn. (See WAXWING.) The general color is reddish olive, passing into purplish cinnamon anteriorly, ashy behind, and yellow below; chin black; under

tail coverts white, but no white on the wings; in other respects like the waxwing. It occurs throughout North America, from Canada to Central America; it is usually seen in flocks,

Cedar Bird (*Bombycilla cedrorum*).

flying high and rapidly. The food consists of berries and small fruits of all kinds, which it eats to repletion and sometimes to its destruction; it takes its name from its fondness for the berries of the red cedar; it also eats insects. It is a handsome and sprightly bird, but has no song. It becomes very fat in summer and autumn, and is then highly esteemed as food in the southern states. It breeds in June, making a nest of grass in orchard and cedar trees; the eggs are three or four, purplish white with black spots. There is a species in Japan, which has no red appendages on the wings.

CEDAR MOUNTAIN, an isolated conical hill in Culpeper co., Virginia, near which was fought, Aug. 9, 1862, a sharp action between a Union force under Gen. Banks, belonging to the army of Virginia under Gen. Pope, and the confederates under Gen. Jackson. Toward evening Gen. Banks fell back to meet supports which Gen. Pope had pushed forward. The confederates retained possession of the battle field, but two days afterward fell back to Gordonsville, toward which Gen. Lee was moving with his whole army. The confederate loss was 223 killed, 1,060 wounded, and 31 missing; total, 1,314. The Union loss was about 1,400 killed and wounded, and 400 prisoners, besides many stragglers who never returned to their commands.

CEDAR SPRINGS, a post village of Spartanburg co., S. C., 5 m. E. S. E. of Spartanburg. It is an old watering place, and the seat of a deaf and dumb asylum, which in 1871 had two instructors and 15 pupils. The Spartanburg and Union railroad passes through the village.

CEDRON, a medicinal extract from the seeds of *simaba cedron*, a small tree of the order *simarubaceae*, growing in Colombia and Central America. The whole plant appears to be impregnated with a bitter principle, al-

though the seeds only are used. Its action on the system appears to be that of a pure bitter. (See BITTER PRINCIPLES.) Antiperiodic virtues are claimed for it when given in larger doses than the ordinary ones of one or two grains. For nearly two centuries it has had a great reputation in its native country as a remedy for the bite of serpents and for the prevention of hydrophobia. It is applied both internally and locally.

CEFALU (anc. *Cephalædis*), a fortified sea-port town of Sicily, on the N. coast, in the province and 39 m. E. S. E. of Palermo; pop. about 12,000. It is the seat of a bishopric, and contains a fine cathedral and several other churches. The remains of a Phœnicidic edifice, a castle built by the Saracens, and several marble quarries are in the vicinity. Sea fishing is prosecuted with great activity. The port is capable of receiving only a small number of vessels.

CEHEJIN, a town of Spain, on the Caravaca, in the province and 35 m. W. by N. of Murcia; pop. about 6,200. It contains numerous handsome houses built of marble from the neighboring quarries, and has manufactories of paper, cloth, soap, and pottery, oil and brandy distilleries, and commerce in wine, fruits, grain, wool, hemp, flax, and cotton.

CELLIER, Dom Rémi, a French theologian, born at Bar-le-Duc in 1688, died at Flavigny, Burgundy, Nov. 17, 1761. He was a member of the Benedictine order, president of the congregations of St. Vannes and St. Hydulphe, and prior of the abbey of Flavigny. His principal work, *Histoire générale des auteurs sacrés et ecclésiastiques* (24 vols., Paris, 1729-'82; new ed., 8 vols., 1858), is celebrated for accuracy and good judgment.

CELAKOVSKY, or Czelakowsky, Frantisek Ladislav, a Bohemian poet and philologist, born at Strakonitz, March 7, 1799, died in Prague, Aug. 5, 1852. He studied at Pisek, Linz, and subsequently at Prague, where he became interested in the Czech language. In 1821 he became instructor in the family of Count Chotek, which left him time for literary pursuits, and he published "Poems" (Prague, 1822; new ed., 1830), "Slavic National Songs" (3 vols., 1822-'7), and a metrical translation of Scott's "Lady of the Lake" (1828). In 1828 he became associate editor of the "Quarterly Review for the Catholic Clergy," and in 1829 published a translation of Russian national songs, which occupies a high place in Bohemian literature. When the Polish insurrection broke out in 1830 he sympathized with Russia; but after the insurrection was suppressed he wrote an article in the "Bohemian Gazette," of which he had become editor, in which he denounced the severity of the Russian government against Poland. In consequence of this article he was deprived of his post as editor of the "Gazette," and also of that of professor of Bohemian literature in the university of Prague, to which he had been appointed. He then became librarian of

Prince and afterward of Princess Kinsky, and in 1842 professor of Slavic languages and literature at the university of Breslau. In 1848 he returned to Prague, where in the following year, as an act of concession toward the Czech nationality, he was appointed by the Austrian government professor of Slavic philology. One of his latest works was the "Popular Philosophy of the Slavic Nations in their Proverbs" (Prague, 1851). He was engaged from the year 1835 in a comparative study of all the Slavic dialects, and parts of its results were published in the form of additions to Jungmann's Czech dictionary.

CELANDINE (*chelidonium majus*), a plant of the order *papaveraceæ*, indigenous in Europe, but never wild in this country. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and when wounded emits a yellow, opaque juice. It contains several peculiar acid and alkaline principles, one of which, chelerethrine, is probably

Celandine (*Chelidonium majus*).

identical with the active principle of bloodroot, a plant to which celandine is botanically allied. Chelerethrine, which receives its name from the intensely red color of its salts, appears to be an acrid narcotic poison. The whole plant is an acrid purgative. The juice is exceedingly irritant, and when applied to the skin produces inflammation and even vesication. It was formerly esteemed in jaundice, in which affection it may have been useful on account of its purgative properties, although it is not improbable that its reputation was largely founded upon the color of its juice. This is applied locally in some skin diseases, and the whole plant is used externally in the south of Europe as a vulnerary. Its real value is probably not greater than that of many other violent purgatives and irritants.

CELEBES, an island of the Malay or East Indian archipelago, under the control of the Dutch, situated E. of Borneo, and like that

island crossed by the equator. It lies between lat. $1^{\circ} 50' N.$ and $5^{\circ} 30' S.$, and lon. 119° and $125^{\circ} E.$, and is bounded N. by the Celebes sea, E. by the Molucca passage and Banta sea, S. by the Flores sea, and W. by Macassar strait, which separates it from Borneo by an average distance of 120 m., though the breadth of the strait is only about 60 m. at the narrowest part. The outline of Celebes is exceedingly irregular, and has been compared to the form of a huge grasshopper. The island is perhaps best described as a nucleus with its centre on the 120th meridian, $2^{\circ} S.$ of the equator, whence radiate four peninsulas: one northward along the 120th meridian to about lat. $1^{\circ} N.$, and thence easterly and northerly about 380 m. to near lon. $125^{\circ} E.$, which is sometimes called the Menado peninsula, and terminates at Cape Polesan in the province of Minahasa; one eastward, known as the Balante peninsula, 182 m. in length, and separated from the preceding by the gulf of Tomini or Gorontalo; one in a southeasterly direction to a distance of 170 m., called the Tabunku peninsula, with the Tolo gulf lying between it and Balante; and one southward, W. of the Boni gulf, which also washes the W. shore of the Tabunku peninsula, to the southernmost extremity of the island, including the Dutch settlement of Macassar. The maximum length of Celebes from N. to S. lies along the 120th meridian, and is nearly 500 m. The greatest distance from E. to W., measured along the northern peninsula, is not far from 300 m. There are about 2,600 m. of seacoast. Wallace says the size of Celebes is about equal to that of Ireland; by the Dutch and other authorities its area is stated to be upward of 70,000 sq. m., or more than twice as great. The population was formerly estimated at between 2,000,000 and 3,000,000, but probably does not exceed 1,000,000.—The interior of Celebes is elevated and generally mountainous, but nowhere volcanic except near the eastern end of the northern peninsula, in a district which it has been conjectured was once a separate island. Each peninsula is traversed by a range of mountains, the loftiest summit in Celebes being Lompo-Batang, near Macassar, 8,200 ft. high. The prevailing rock in this part of the island is limestone, resting on basalt. A considerable thickness of vegetable mould is found even on the hill tops and steeper mountain slopes. There are 11 volcanoes in Minahasa, and earthquakes are of frequent occurrence there. The principal volcanic peaks are Mt. Klabat, 6,560 ft.; Mt. Lokon, 5,140 ft.; Mt. Sudara, "the Sisters," consisting of twin cones, of which the highest is 4,390 ft.; and Batu Angus, in Malay "the Hot Rock," which is in fact a volcano with its top blown off, and has an elevation of 2,290 ft. The rocks of this region are trachytic lavas, volcanic sand and ashes, pumice stone, and conglomerates. The decomposition of volcanic products has rendered whole districts prodigiously fertile. Hot springs and miniature volcanoes which emit boiling mud exist in this

portion of Celebes.—The largest river of the island is the Chinrana, which flows from Lake Labaya a distance of 53 m. into the Boni gulf. The lake, which is also called Sedenveng, is in the country of the Bughis, whose boats throng its waters. It is 24 m. long, 13 m. wide, and varies in depth, according to the season, from 32 to 60 ft. In Minahasa, the lower part of an elevated plateau is occupied by a beautiful lake called Tondano, at a height of 2,272 ft. above the level of the sea. It extends about 17 m. in a northerly and southerly direction, and is from 2 to 7 m. wide. Its greatest depth is 74 ft. A stream of considerable size known as the Boli enters the sea on the N. coast, and on the W. coast, S. of Macassar, is the mouth of another river. The island is for the most part well watered by small streams.—The natural history of Celebes presents some striking peculiarities. The island is not only remarkable for the individuality of its animal productions, but also for the absence of groups found elsewhere throughout the region of zoölogical distribution of which it is the geographical centre. Wallace says that in order to account for the number of animal forms possessed by Celebes which show no relation to those of India or Australia, we must assume that it is one of the oldest parts of the archipelago, and dates from a period when the land that constitutes Borneo, Java, and Sumatra had not risen above the ocean. Of the 14 species of terrestrial mammalia, 10 are peculiar to the island, a lemur, a deer resembling a Javan species, and the common Malay civet being met with elsewhere as well. Among those which are distinctive, the most noteworthy is the sapi-utan or wild cow of the Malays (*anoa depressicornis*), which frequents the mountains only, and is described as a creature resembling the ox-like antelopes of Africa. The other mammalian species peculiar to Celebes are: a black baboon-like monkey (*cynopithecus nigrescens*), with a tail scarcely long enough to be visible; a peculiar wild hog; five species of squirrels; and two species of eastern opossums. Seven species of bats are known to exist. The island is the chief habitat of the babyroussa. Of birds there are 191 species, 128 of which are land birds, and 80 strictly confined to Celebes. They comprise hawks, crows, parrots, owls, woodpeckers, cuckoos, bee-eaters, hornbills, fly-catchers, starlings, pigeons, and the curious maleo (*megacephalon rubripes*), a gallinaceous bird allied to the Australian brush turkey. Pythons and other serpents are very numerous, the former attaining a length of 15 ft. Insect life is abundant, the number of peculiar species being large. Millipeds 8 and 10 inches long frequent houses in the rainy season.—The uncultivated portions of Celebes are covered with forest, abounding in the luxurious vegetation of an equatorial climate, such as pandani, tree ferns, the wild jackfruit tree, and palms, including the cocconut, the betelnut, the sago, the sugar palm (*arenga saccharifera*), and the gomuti palm, the

fibres of which are manufactured by the natives into a sort of coarse rope called coir. The fruits of Celebes are bananas, breadfruits, durians, lansiums, limes, mangosteens, oranges, pineapples, pompelmuses or shaddocks, and those already referred to. Rice and coffee are the most important agricultural productions. Cacao, cotton, maize, and tobacco are also raised, the last named only for home consumption. Rice can be profitably cultivated up to an elevation of 4,500 ft., and coffee between that and an altitude of 1,000 ft. above the sea level. The annual yield of the Dutch government coffee plantations on the table lands of Minahasa is about 5,000,000 lbs. The coffee raised here is superior to any from Java, and commands a higher price. Gold occurs in very considerable quantities, not only throughout the whole northern peninsula, but also near the southern extremity of the island, S. of Macassar. It is sold by the native chiefs to the Bughis, who pay for it more liberally than the Dutch. The iron ore of the island is of a superior quality, and tin and copper are also found.—The native inhabitants of Celebes are in part governed by their own kings, but these are dependent upon the Dutch government. All appear to belong to the Malay race. The Bughis constitute the most numerous and active portion of the population, and are famed as sailors and traders throughout the archipelago, every important island of which is visited by their light vessels known as praus. They occupy that part of the S. W. peninsula lying between lat. 3° 30' and 5° S. They are one of the four true Malay tribes, Mohammedans in religion, and speak the Bughis and Macassar languages, for which they have two different written characters. The Bughis sailors are wild and ferocious in appearance, but of quiet and peaceable disposition. The aborigines of northern Celebes are classed with the savage Malays, although the civilizing influence exerted by the Dutch since the introduction of coffee cultivation in 1822 has greatly promoted their advancement. They are short in stature, of light-brown complexion, with projecting cheek bones, and have long, straight, black hair. Up to a comparatively recent period they were addicted to head-hunting like the Dyaks of Borneo, and even to cannibalism; but they are obedient servants, gentle and industrious, and readily assume the manners and habits of civilized life. A people called the Mandhars dwell in the most western part of the island, N. of Macassar. Menado, the Dutch capital of the northern portion of the island, is a free port and town of 2,500 inhabitants, on the Celebes sea. Kema is a place of 2,000 inhabitants on the opposite shore, used as the port of the province during the prevalence of the western monsoon, which renders Menado difficult of access for ships. Macassar or Vlaardingen, the chief Dutch town on the island, in lat. 5° 9' S., lon. 119° 36' E., is a fortified free port, with good anchorage, and carries on a considerable trade with China,

especially in tripang or sea slugs, of which the yearly exports are valued at \$600,000. Other articles of export from Celebes, in addition to coffee and rice, comprise tortoise shell, which is abundantly obtained on the coasts, Macassar horses, which are sold in Java, and variegated mats.—The first mention of Celebes by any European writer is believed to be in a work by the Portuguese historian De Barros, who lived in the 16th century and wrote an account of the conquests of his countrymen in the East Indies. According to this, the island was discovered in 1525 by Portuguese from the Moluccas, who sought *si labih*, "still more" gold and spices than they had already found. Touching at the points of two peninsulas, they believed they had visited two islands, and so described the discovery in their report as *as ilhas Celleses*, a designation which has remained substantially unchanged. This name, however, is not known to the natives, who generally call the country Negri Bughis, or Bughis land. The conversion of the more advanced tribes of the island to Mohammedanism was effected a few years after the arrival of the Portuguese, in spite of the efforts of their Christian missionaries. The first intercourse of the Dutch with the island was in 1607. They expelled the Portuguese from the Macassar country in 1660, and establishing themselves on the island maintained their position there until expelled by the British in 1811. Their possessions were restored to them by the treaty of 1815.

CELERES, in Roman antiquity, a body guard instituted by Romulus, composed of 300 young men of the most illustrious families. They were elected by the suffrages of the 30 curiæ, each of which furnished 10. The name has been derived by some from the name of their first chief, but more probably was given to them in allusion to the rapidity with which they executed their orders. Their commander was called the tribune of the celeres, and was, after the king, the highest officer in the state. This office was held by Brutus when he expelled the Tarquins from Rome. The celeres are thought by Niebuhr to have been the patricians in general, so called because they could keep horses or fought on horseback, and thus to correspond with the later *equites* or knights.

CELERY (*apium graveolens*, Linn.), an umbelliferous plant chiefly cultivated for salad. In its wild state, in which it is found in ditches throughout Europe, it is rank, coarse, and even poisonous; but by cultivation in gardens it becomes sweet, crisp, juicy, and of an agreeable flavor. Its green leaves, stems, and seeds are used in soups, and the blanched stalks either in that way, or more usually as a salad. One variety, called the celeriac, is raised only for the root or base of the leaves, which becomes a white, solid bulb. Celery requires a deep, rich, well drained soil. The seed is sown in a bed, from which the plants are transferred to another when they are 2 or 3 inches high. At 8 or 12 inches' height they are transferred for

blanching to trenches which are nearly a foot in depth. The plants are repeatedly earthed up till they have risen two feet or more above the

Celery (*Apium graveolens*).

natural surface. Celeriac is not blanched, but grows openly, exposed to the light.

CELESTE, Madame, an English dancer and actress, born in Paris, Aug. 16, 1814. Though of French parentage, and a pupil of the conservatory of the then royal academy of music, she has been connected from her earliest life with the English and American stage. In her 15th year she came to the United States, where she married Mr. Elliot; but her husband soon dying, she left for England, and in 1830 made her first appearance in Liverpool as Fenella in *Masaniello*. She soon became very popular, especially in London, as Matilda in the "French Spy." In 1834-'7 she again performed in the United States, where she acquired a considerable fortune. In 1837 she first appeared as an actress at Drury Lane and the Haymarket theatres, London, and in 1838-'40 in the United States. In 1843 she joined Mr. Webster in the management of a theatre at Liverpool, and in 1844 of the Adelphi in London; and subsequently she was the lessee of the Lyceum till about 1861, having revisited the United States in 1851-'3, where she appeared again in 1865, still displaying undiminished histrionic power. Her most popular parts were Miami in the "Green Bushes," Miriam, and the Woman in Red. She returned to England in 1868, and retired from the stage Oct. 22, 1870.

CELESTINE, the name of five popes. **I. Saint**, a Roman, died April 6, 432. He was related to the emperor Valentinian II., was created cardinal deacon by Innocent I., and succeeded Pope Boniface, Nov. 3, 422. The heresy of Nestorius induced him to convoke the council of Ephesus in 431, at which there were 200 bishops assembled, and which was presided over by his three legates. Celestius, the chief

of the Pelagians, having retired into Britain, he sent missionaries there, who in the space of two years brought back that country to the faith. Shortly after this he sent Palladius to Scotland, and St. Patrick to Ireland. Some epistles of this pope have been preserved, but those written to the bishops who had taken part in the election of Nestorius and to Fuen-gius have been lost. **II. Guido di Castello**, a disciple of Abélard, died March 8, 1144. He was created cardinal priest by Honorius II., and made governor of Benevento by Innocent II., at whose death he was elected pope, Sept. 26, 1143. As soon as he had ascended the pontifical throne he received ambassadors from Louis VII., who came to supplicate peace, and also absolution from the ecclesiastical censures under which the kingdom had been laid by his predecessors. The pope granted their request in the presence of the nobles of Rome. He held the see five months. Only three epistles of his are extant. **III. Giacinto Orsini**, born in Rome in 1106, died Jan. 8, 1198. He was created cardinal by Honorius II., and elected pope when past 80 years of age, March 30, 1191. The day after his consecration he crowned the emperor Henry VI. and his empress Constance. After the coronation the emperor restored to the pope the city of Tusculum, which the latter gave to the Roman citizens, who, to avenge some former disputes, destroyed it. He afterward excommunicated the emperor, because he kept Richard Cœur de Lion in prison. Among other noteworthy events of Celestine's pontificate was his confirmation of the Teutonic military order in 1192. **IV. Goffredo Castiglione**, of Milan, elected pope, Sept. 20, 1241, died Oct. 8, 1241. He was appointed canon and chancellor of his native city, and afterward became a monk in the monastery of Altacomba. In 1227 Gregory IX. created him cardinal, and sent him as legate into Tuscany, and after this to Lombardy and to Monte Casino, where he found the emperor Frederick II. preparing to send succors to the Holy Land. Advanced in years at the time of his election, and with health much impaired, he died without having received consecration, and without having published any bull. **V. Pietro Angelerier**, born at Isernia, in Naples, died May 19, 1296. He was known as Pietro da Murrone, from a mountain near Sulmona, where he led a solitary life. When 17 years old he became a Benedictine monk in the monastery of Faifoli, in the diocese of Benevento. After performing extraordinary penances for many years, he went to Rome, where he was ordained priest in 1239. Having spent five years at Murrone, he afterward removed to Mount Majella, near Sulmona, where he lived with two other priests in a large cavern. He fasted every day except Sunday, and observed four Lents in the year, living on bread and water, working and praying during the entire day and most of the night. About 1254 he founded the religious order called Celestins, which prospered so much during his lifetime

that it consisted of 600 monks and 36 monasteries. This order was approved by Urban IV., who incorporated it with the Benedictine order. Gregory X. confirmed it in 1274, in the second general council of Lyons. It spread throughout Italy, France, and Germany, and was suppressed in 1778. Pietro was elected pope July 5, 1294, after an interregnum which followed the death of Nicholas IV. The account of his election being forwarded to him in his retirement, he refused to accept the dignity, though the cardinals and Charles II. of Naples and Andrew III. of Hungary urged him strongly to do so. He attempted to fly from his retreat, but was prevented by a vast concourse of people. At length he consented, and proceeded to Perugia accompanied by the kings of Naples and Hungary, and was crowned Aug. 29. He made his public entrance into the city amid the applause of more than 200,000 people. In the city of Aquila he appointed twelve cardinals, five of whom were Italians and seven French, and then went to Naples. He made two constitutions which provided for the cardinals entering into conclave on the election of a pope, thus renewing a constitution already made by Gregory X. in the council of Lyons; and also another respecting the pope resigning his office. After occupying the pontifical see during five months, he renounced the tiara, Dec. 13, 1294, on finding that he was but little acquainted with temporal matters, and still retained his unconquerable love for solitude. The see remained vacant ten days, when Boniface VIII. was elected his successor. Celestine then retired again to his solitude at Majella, to devote himself altogether to prayer and to mortification. Boniface VIII., fearing difficulties might be caused by artful persons, who would turn his simplicity to their own account, wished to keep him under his control, and at first confined him in a house in Anagni near his own residence, and afterward transferred him to Fumone, near Ferentino in the Campagna, where he languished for ten months in a climate so sickly that the religious who waited on him were obliged to be changed every two months. He finally died there, and was canonized at Avignon by Pope Clement V., May 5, 1313. He wrote the following treatises, which were published at Naples in 1640: *Relatio Vitæ suæ*; *De Virtutibus*; *De Vitiis*; *De Hominis Vanitate*; *De Exemplis*; *De Sententiis Patrum*. Several lives of this pope have been written; among them one by Lelio Marini (Milan, 1630).

CELESTINS. See CELESTINE V.

CELIBACY (Lat. *calēbs*, unmarried), the state of being unmarried, whether the person be a bachelor or a widower, a maid or a widow. In its restricted and more usual sense, it means the state of those who have formally renounced matrimony for the future, especially by a religious vow. In ancient Greece and Rome celibates, outside of the priesthood, were subjected to various penalties. In Sparta un-

married men were regarded as infamous, and by the laws of Lycurgus might be seized and severely punished by the women in the temple of Hercules. Plato, in his imaginary republic, declared all those who had remained unmarried till they were 35 years old to be incapable of holding any public office. At Rome celibates were forbidden to bear witness in courts, or to leave a will, and it was believed that special penalties were reserved for them in the future life. It is remarkable that while celibacy was proscribed in Europe, it was authorized in the East. There celibates bore honorable names, were raised to high positions, and styled favorites of heaven. With the progress of civilization in Greece and Rome celibacy became more common. Thus often the men of letters, the philosophers, athletes, gladiators, and musicians, some from taste, and some from necessity, remained unmarried. This was frequently the case with the disciples of Pythagoras and Diogenes. Celibacy was early regarded as a peculiar privilege and duty of the priesthood. Among the Hebrews, persons intended for the service of the temple were permitted to marry, but under certain restrictions. Among the Egyptians, the priests of Isis were bound to chastity. The gymnosophists of India and the hierophants of the Athenians lived in celibacy. There were maidens among the Persians consecrated to the worship of the sun, and vestal virgins among the Romans, who alone were permitted to guard the sacred fire. The celibacy of religious persons was regarded by the Greeks as a grace almost divine. No sacrifice was regarded as perfect without the intervention of a virgin.—In the primitive Christian church celibacy came gradually to be esteemed a higher state than matrimony. The early fathers, especially St. Jerome, enthusiastically celebrated the virtue of continence. Yet there was no law nor uniformity of opinion or action on the subject, and it was not till the 4th century that even the higher clergy began generally to live in celibacy. The council of the Spanish and African churches at Elvira, in Spain, about A. D. 305, commanded ecclesiastics of the three first grades to abstain from conjugal intercourse under penalty of deposition. A motion to the same effect was made in the general council of Nice, in 325, but it was rejected. Yet a tradition became prevalent about that time, that priests once admitted into holy orders should not afterward marry; and this practice, being once established, led naturally to the opinions that persons who were married should not be admitted into orders, and that celibacy was a holier state than marriage. In the Latin church the usage of celibacy was most strictly observed. Near the close of the 4th century Pope Siricius forbade conjugal intercourse to priests without distinction, and this interdiction was repeated by the subsequent popes and councils. The emperor Justinian declared the child of an ecclesiastic illegitimate, and incapable of being an heir. The

council of Tours in 567 decreed that married monks and nuns incurred excommunication, and that their marriage was null. The Greek church opposed the action of the Latins, and the regular clergy of that church cannot be celibates. A priest, however, can be married only once, and if his wife dies he must go into one of the monastic orders. The monks and the bishops, who are chosen from among them, are unmarried. In the Roman church councils were frequently occupied with rigorous measures against violations of the law of celibacy; and observance of the law was most strictly insisted upon under the pontificate of Gregory VII., who excommunicated every married priest, and every layman who should be present at a service celebrated by him. The reformers rejected celibacy as contrary to natural law, and permitted Protestant ministers to marry. This innovation brought the question up again in the Catholic church, and although the emperor, the king of France, and many of the electors and princes were favorable to the marriage of priests, yet the council of Trent, which closed its sittings in 1563, decided finally to retain the discipline of celibacy. From that time the law has been absolute in the Roman Catholic priesthood. One who has been married cannot be ordained if his wife is living, unless a separation takes place between the parties by mutual consent. Those who have yet attained only the lower orders may renounce their benefices, forsake their orders, and be married; but it is otherwise with subdeacons and the higher degrees. To such the pope alone, notwithstanding the indelibility of the character of priests, may grant permission to retire from the priesthood, and consequently to contract marriage.—See "History of Clerical Celibacy," by H. C. Lea (Philadelphia, 1867).

CELL, a microscopic anatomical form, very abundant in most vegetable and many animal tissues. It has received its name from the fact that in its simplest form it consists of a closed membranous sac or utricle, more or less globular in shape, enclosing a cavity which is filled with a fluid or semi-fluid material. This is the variety of cell which is found in many loose and succulent vegetable tissues. The cell wall usually has upon some part of its inner surface a well defined rounded or oval spot, termed the nucleus; and the nucleus exhibits also a smaller rounded spot of a darker color than the rest, termed the nucleolus. In tissues where the component cells are very abundant and closely set, they are often polyhedral in form, being flattened against each other by mutual compression. Sometimes they are elongated and tubular or prismatic. The elongation of the vegetable cell is sometimes so great, as in certain of the algæ or cryptogamic water plants, that they form, by being connected with each other end to end, long and slender filaments. This also occurs in some of the higher vegetable structures. Other cells send out radiating

processes or prolongations, so as to present a stellated figure. The internal cavity is sometimes partly occupied by a solid deposit upon the inner surface of the cell wall; sometimes it contains a gelatinous liquid, granules of chlorophyl or the green coloring matter, starch grains, and sometimes perfectly formed crystals. There are three great groups of the cryptogamic vegetables, namely, algæ, lichens, and fungi, which consist exclusively of cells; in the higher vegetable forms we find also fibres, air tubes, and vessels. The simpler vegetable cells often multiply very rapidly by a process of budding, or by spontaneous division, or by both combined. They have the power of absorbing nutritious material from the exterior, and converting it into the substance of their own material.—The cells of animal tissues are not precisely similar to those of vegetables. They are usually much smaller, and surrounded by a larger proportion of intercellular substance. They do not, as a rule, present a well marked cell wall enclosing a distinct cavity, but consist rather of a mass of soft animal matter, the consistency of which is nearly or quite the same throughout. Very frequently a nucleus and nucleolus, similar to those seen in vegetable cells, are imbedded in its substance. Thus the red globules of the blood in birds, reptiles, and fish contain a well marked nucleus, though it is absent in those of the mammalia. The nucleus and nucleolus are both very distinct in the cells of the gray nervous matter, and the various kinds of epithelial cells have always a nucleus and usually also a nucleolus. Animal cells also vary in form. The red globule of human blood is flattened and circular; in birds, reptiles, and fishes, it is flattened and oval. The epithelial cell covering the surface of mucous membranes is thin, membranous, and pentagonal or hexagonal in the mouth, fauces, and œsophagus; columnar or prismatic in the rest of the alimentary canal; furnished with vibratile cilia in the air passages, the oviducts, the Eustachian tube, and the ventricles of the brain. There are also hexagonal pigment cells in the choroid coat of the eye, and stellated pigment cells in the web of the frog's foot. The glandular cells of the liver always contain one or more minute oil drops imbedded in their substance. It has been a favorite theory with many microscopists that all the anatomical elements of the animal tissues are directly produced by the development or transformation of simple cells; but this view has never been universally adopted, and the evidence in its favor does not become more convincing with the progress of microscopic discovery.

CELLAMARE, Antonio Giudice, prince of, duke of Giovenazzo, a Spanish diplomatist of Genoese origin, born in Naples in 1657, died in Seville, May 16, 1733. Brought up at the court of Charles II. of Spain, he afterward fought the battles of his successor, Philip V., against the imperialists. Taken prisoner in 1707, he was detained till 1712. Three years after his re-

turn to Spain he was sent to France as ambassador. Here he joined in the conspiracies planned against the duke of Orleans, with a view of vesting the regency of France in Philip of Spain; but the plot was discovered, and the seizure of Cellamare's despatches laid bare the whole details. He was sent out of France at once, and on his return was appointed captain general of Old Castile, in which post he died.

CELLARER (Lat. *cellarius*), under the Roman emperors, a functionary who examined the accounts, and to whom was committed the care of their domestic affairs. The name was subsequently given to the purveyors or agents for prelates and monasteries. The cellarer was one of the four great officers of monasteries, and had under his orders the bakehouse and the brewhouse. He regulated the harvesting and storing of the corn, and managed the whole economy of the provisions. His compensation was $\frac{1}{3}$ of all the grain received, and a furred gown. The office was sometimes held by persons of illustrious birth. Philip of Savoy, in 1243, was cellarer to the archbishop of Vienna.

CELLARIUS, Christoph, a German scholar, born at Smalcald, Nov. 22, 1638, died in Halle, June 4, 1707. He devoted himself so closely to the study of the oriental languages and literature, that it is related of him that during the 14 years he was professor of history and elquence at the university of Halle, he only once went out for a walk. He edited more than 20 Greek and Latin classical works, and wrote several volumes on the grammar, geography, history, and languages of oriental countries.

CELLE, or **Zelle**, a town of Prussia, in the province of Hanover, on the river Aller, which is here navigable, and on the Hanover and Harburg railway, 24 m. N. E. of Hanover; pop. in 1871, 16,147. It is a well built and paved town, the seat of the supreme court of Hanover, contains churches of different denominations, an old castle formerly occupied by the dukes of Lüneburg, a Protestant gymnasium, two public libraries, an agricultural society, and various other public institutions. Celle is also noted for its annual horse races. In the castle park is the mausoleum of Caroline Matilda, queen of Denmark, who died here. The inhabitants are employed in the manufacture of tobacco, cigars, and stearine, and carry on transit trade in wool, wax, honey, and wood.

CELLINI, Benvenuto, an Italian artist, born in Florence in 1500, died there, Feb. 25, 1570. He was intended for the musical profession, to which his father was devoted, but gave the preference to the pursuits of a gold worker and engraver, and soon distinguished himself in chasing sword handles, cutting dies, and engraving medals. His headstrong disposition involved him in brawls and quarrels; and at the age of 15, when his genius had already excited the admiration of his townsmen, he was banished to Siena for having taken part in a duel. After wandering for some time from one town to another, he found his way to Rome, where

a gold medal of Clement VII., of which he had furnished the die, secured him the favor of the papal court. The pope took him into his service, and this position gained him employment in cutting seals for many eminent prelates. He also took part in the defence of the castle of San Angelo, against the imperial troops commanded by the constable de Bourbon, and asserted that he killed the constable and the prince of Orange. At Mantua, where he remained until an affray compelled him to leave the town, he became acquainted with Giulio Romano, and through him with the grand duke, who gave him some commissions. On his return to Florence, where his military exploits at Rome had reinstated him in the good graces of the authorities, he formed an intimacy with Michel Angelo. While at Florence he devoted himself principally to the execution of medals, the best of which are Hercules and the Nemean lion, and Atlas supporting the globe. But another quarrel in which he became embroiled compelled him to leave Florence in disguise. He went to Rome, and was there appointed engraver to the mint. He soon found himself again in trouble, and a mistress of his named Angelica having fled to Naples, he followed her thither. He afterward returned to Rome, and remained for a considerable time in the service of the new pope Paul III., although his natural son, Pier Luigi, was hostile to him, and caused him to be imprisoned upon a charge of having robbed the castle of San Angelo during the war. He effected his escape, and through the interference of the cardinal of Ferrara obtained pardon. Subsequently he was employed in France, at the court of Francis I.; but in consequence of differences with the duchess d'Étampes he returned to Florence, where the grand duke Cosmo de' Medici supplied him with a studio. Here he commenced his celebrated "Perseus," which as soon as it was exposed to public view created the utmost enthusiasm. He was employed upon many important works, and was not able to accept a proposition made to him by Catharine de' Medici to superintend the execution of a monument to be dedicated to Henry II. He remained in the grand duke's service until his death, and was buried with great pomp in the church of Sta. Annunziata. He left an autobiography, which is interesting as a record of the incidents of his stirring life, and of the history and manners of his times. It has been translated into German by Goethe, into French by Farjasse and A. Marcel, and into English by Nugent and by Roscoe. The best edition, from which Roscoe's translation was made, is that of Carpani of 1812. Cellini also left MSS. on various branches of art, and the academy della Crusca quotes him frequently as a classic. The best part of his artistic works are his smaller productions in metals, the embossed decorations of shields, cups, salvers, ornamented sword and dagger hilts, clasps, medals, and coins; the most celebrated specimens of his

skill in these branches of art are a richly ornamented salt-cellar in the imperial gallery at Vienna, and a magnificent shield at Windsor castle. Of his larger works, the bronze group of Perseus, with the head of Medusa, in the piazza del Gran Duca at Florence, and his "Christ" in the chapel of the Pitti palace, are the finest.

CELLULAR TISSUE, a name given by the older anatomists to a tissue formed by a mixture of white and yellow fibres, extensively diffused in the animal body under the names of cellular, fibro-cellular, areolar, and fibrous tissue. The best name is areolar tissue, derived from the appearance of *areolæ*, or meshes, left between the intricate crossings of the component fibres; these were formerly mistaken for cells or cavities; the old term cellular tissue, however, is so well and universally understood, that, though inaccurate, it will probably long be employed in this application. Its principal use seems to be to connect other tissues, allowing at the same time more or less freedom of motion between them; it supports the vessels and nerves in their minutest branches; it is abundant under the skin and the mucous and serous membranes; it enters largely into the formation of membranes, hence often called cellular membranes, protecting the organs and cavities by their toughness and elasticity. The spaces of the cellular tissue are continuous throughout the body, as may be proved by artificial inflation by the blowpipe, and as is frequently seen in cases of emphysema and anasarca, where air or fluid is effused into its meshes. Under the microscope this tissue presents two kinds of fibres, inextricably mingled in various proportions. The one is white and inelastic, disposed to a waved or zigzag arrangement in bands of unequal thickness, creased longitudinally by numerous streaks; the largest of these bands are often $\frac{1}{80000}$ of an inch wide; the component fibres do not branch, according to Hassall; this is the white fibrous tissue. The other kind of fibre is elastic, of a yellowish color, composed of branched filaments disposed to curl when not put on the stretch; they are generally about $\frac{1}{80000}$ of an inch thick, interlacing with the others without becoming continuous with them; this is the yellow fibrous tissue. These two elements of the cellular tissue may be at once distinguished by submitting it to the action of dilute acetic acid, which instantly causes the former to swell up and become transparent and soft, while it causes no change in the latter. Cellular tissue is especially abundant in parts which enjoy free motion, as in the face about the eyes and cheeks, the anterior part of the neck, the armpit, the flexures of the joints, the palm of the hand, and the sole of the foot; the superficial and most movable muscles are separated by thicker layers than the deep-seated ones, and the constituent fibres are held together by it during contraction; almost every part of the vascular system is held in place by this tissue,

whose elasticity protects the vessels during the necessary movements of the body; even its own minute but numerous vessels are conducted and enveloped by this all-pervading tissue. It is difficult to say where cellular tissue is not found, unless it be in the teeth, in bone, in cartilage, and in the cerebral substance, where its presence would be manifestly useless. The internal vital organs most exposed to external violence are protected by large quantities of this substance, as the pancreas, kidneys, colon, and genito-urinary apparatus; every organ has its investing covering of cellular tissue, and its processes of the same penetrating and holding together its component parts. It is especially abundant just under the skin, to facilitate its movements, and it exists in uncommon quantity about and in the interior of the mammary glands. Thus this tissue seems to serve as a bond of union between parts, as an element of strength and protection rather than as a substance of primary importance in itself; wherever elasticity is required, the yellow fibrous tissue is most abundant, while the white fibrous tissue prevails in parts demanding resistance and tenacity; and the openness of the meshes is in proportion to the amount of mobility needed. The amount of cellular tissue varies with age and temperament, being greatest in youth and least in old age; the plumpness and roundness of the arms in children and females depend to a great extent on the presence of this substance around the joints, which in man are prominent and angular. Like other soft solids, it contains a small quantity of serous fluid in its interstices, which is favorable for the free movement of the fibres; an unnatural increase of this fluid in the subcutaneous cellular tissue causes the form of dropsy called anasarca, so common about the feet and ankles, and indicated by the skin pitting under the pressure of the finger. In the English training process it is rapidly lessened, with a remarkable diminution of the bulk of the body; its natural and slow disappearance is seen in old age and in chronic disease, in which the skin, especially about the face and neck, becomes wrinkled and flabby. Its power of reproduction is great, and it is rapidly formed both in healthy and morbid growths; it undergoes the putrefactive process slowly, and when boiled yields gelatine from its white fibrous element.—So extensive a tissue as this must of necessity become involved in many diseases; it is subject to all the effects of inflammation, with suppuration and mortification; to the infiltration of blood, serum, air, and urine; to induration, tumors, and unnatural increase and degeneration. In common inflammation of this tissue, the capillaries become congested, and a part of their contents escapes, more or less tinged with blood; the coagulable lymph thus effused causes the hardness of circumscribed inflammation; this may be removed by absorption, or may become softened by the deposition of purulent matter, constituting an abscess, whose walls are formed

by an indurated layer of the tissue which prevents the pus from spreading indefinitely. When an abscess is formed, the cellular tissue between it and the surface of the skin is removed by ulceration or absorption, or the pus is evacuated by the knife; when from excess of inflammation or other cause the capillary circulation is permanently suspended, the vital properties of the tissue are destroyed, and mortification takes place, the dead parts being removed in offensive fluids and pulpy shreds. In chronic inflammation the cellular tissue becomes indurated. In debilitated conditions of the system, after poisoned wounds, and in certain epidemic alterations of the air, the usual barrier of circulating lymph is not effused, and the products of inflammation spread extensively through the areolæ of the subcutaneous and internal cellular tissue; this is familiarly seen in phlegmonous erysipelas, and constitutes a most dangerous disease from the extensive suppuration and sloughing of the tissues. In wounds of the lungs a communication is often established between the air passages and this tissue, when the integuments are variously raised by the infiltration of air in the areolæ, constituting external emphysema; a similar condition is artificially produced by the butcher when he blows up his meat. It grows with such rapidity that tumors, often of large size, are developed from it; most so-called "fibrous" tumors are composed of this tissue; in such cases the microscopist is able to detect the fusiform cells and fibres characteristic of the natural tissue.

CELSIUS. **I. Anders**, a Swedish astronomer, born Nov. 27, 1701, died in Upsal, April 25, 1744. His grand-uncle, Magnus Celsius (1621-'79), an astronomer, was the discoverer of the Helsing runes. His uncle, Olaf Celsius (1670-1756), a theologian, was one of the founders of the scientific society of Upsal, author of *Hierobotanicon* (Upsal, 1745-'7), and the first to recognize the genius of Linnæus. His father, Nils Celsius (1658-1724), was a mathematician and naturalist. Anders was professor of astronomy at Upsal 1730-'32, when he visited Doppelmayer in Nuremberg, where he published *Observationes Luminis Borealis*. He next went to Rome, and in 1734 to Paris, where he subsequently joined Maupertuis and his associates in the measurement of the Lapland degree of longitude. On his return to Upsal he published *De Observationibus pro Figura Telluris determinanda in Gallia habitis*. The observatory of Upsal was established in 1740 under his auspices. He was the first to employ the centigrade, also known as the Celsius thermometer. **II. Olaf de**, a Swedish historian, cousin of the preceding, born in 1716, died in 1794. In 1747 he became professor of history at Upsal, was afterward raised to the nobility, and in 1756 founded the first literary journal in Sweden. In 1777 he became bishop of Lund, and in 1786 a member of the Swedish academy. His principal works

are a history of Gustavus I. (2 vols., Stockholm, 1746-'53; 3d ed., 1792; German translation, Copenhagen, 1753), and a history of Eric XIV. (1774; German and French translations, 1777).

CELSUS, an Eclectic philosopher of the 2d century. He was the author of a work against Christianity, entitled *Ἀληθῆς Λογός*. The work itself is not extant, but a large part of it is contained in the answer to it written by Origen a century later. He was skilled in both the Epicurean and Platonic philosophies, and argued *à priori* against the doctrines of the Christian religion. From the statement given by Origen of his arguments, however, his chief reliance would seem to have been on sarcasm and ridicule. He is admitted by some of the Christian fathers to have exhibited great keenness and wit. His work was the first which was written in opposition to Christianity after it became known to the Greeks.

CELSUS, Aulus Cornelius, a Roman author, who lived probably during the reigns of Augustus and Tiberius. He wrote a kind of cyclopædia, *De Artibus*, containing a series of treatises on rhetoric, history, philosophy, jurisprudence, war, agriculture, and medicine, of which, besides some fragments, only *De Medicina* is still extant. This work is in eight books. He makes known in it the system of Hippocrates, following besides Asclepiades and the Alexandrians. The first two books treat of diet and the general principles of therapeutics and pathology; the others of particular diseases and their treatment, as well as of surgery. Of its numerous editions, those by Fortius (Florence, 1478), Milligan (Edinburgh, 1826), and Ritter and Olbers (Cologne, 1835), are the best.

CÆLTIBERIANS (Lat. *Celtiberi*), the people who during the time of the Romans occupied the inland district of Spain lying between the Ebro and the Tagus. The name was sometimes used in a wider sense, including also nearly all the inhabitants of Hispania Citerior. The Celtiberians arose from the mixture of two races, the Celts and the Iberians. Many have supposed that the Iberians were the original inhabitants of Spain, and that the Celts crossed the Pyrenees and invaded their country. Niebuhr was of the contrary opinion, and believed that the Celts once occupied Spain as far south perhaps as the Sierra Morena, and that the Iberians afterward landed from the Mediterranean and drove them northward, expelling them where they were not protected by the nature of the country. The Celts would seem, in Niebuhr's opinion, not to have been expelled from the mountainous country between the Ebro and the Tagus, but merely to have been subdued by the Iberians, who settled among them, and the two nations became amalgamated. The race thus produced retained in a high degree the qualities of the original Iberians. They were with great difficulty subdued by Hannibal, and made a long and obstinate resistance to the Romans. Scipio

induced them to become allies of the Romans; but they revolted in 181 B. C., and renewed the war from time to time during more than a century. After the fall of Sertorius, 72 B. C., they began to adopt the Roman language, dress, and manners, and their country gradually became an integral part of the Roman empire. The great mass of the people inhabiting the central portions of Spain under all these changes retained, and indeed still retain, the essential characteristics of their ancestors. The Celtiberians, like the modern Spaniards, were grave in dress, sober and temperate in their habits, and of an unyielding disposition. Like the modern Spaniards, they were remarkable for the bitter animosity with which they warred against their neighbors, and for the obstinate courage with which they endured protracted sieges. (See **IBERIA**.)

CELTS (Lat. *Celtæ*; Gr. *Κέλται*), a people of the Aryan or Indo-European family, who in prehistoric times, and probably before the migration of any other Aryan tribes, passed over from Asia into Europe. Subsequent migrations drove them gradually further and further to the westward; and after overspreading many regions in their passage (for evidences of their residence are found in most of the European countries), they appear at the very beginning of the historic period to have so entirely passed away from the eastern portion of the continent, and to have so firmly settled in the regions afterward called Transalpine Gaul and the British isles, that ancient historians believed them to be an autochthonous race, the natives and original possessors of those lands. This theory was strengthened by the fact that the tide of their progress now began to return upon itself; the earliest records showing that even at a remote period they sent out armies and emigrants toward the east, in a direction exactly opposite to the first current of their migration. As early probably as the 5th century B. C. Celts had subdued that part of northern Italy afterward called from their later name Gallia (Cisalpinia), and had become firmly settled in the country; they had planted vigorous colonies (Vindelicians, &c.) in southern Germany, near the E. bank of the Rhine; and from these in turn they penetrated, chiefly under the names of Rhæti, Boii, Norici, and Carui, into the western regions of modern Austria. Nearly all the territory now included in Switzerland seems also to have been held by them. Celtic tribes, too, had crossed the Pyrenees into Spain, and settled in the country; and from them and the Iberians, the older residents of the peninsula, sprung the mixed race of the Celtiberi, forming a famous nation in the centuries which followed.—The Spanish branch of the Celts was the first to find mention under the name of the race in authentic written records; and Herodotus only noticed this tribe briefly, as living “beyond the Pillars of Hercules, and bordering on the Cynesiensians, who dwell at

the extreme west of Europe.” (Book ii., 33.) But soon after his time the great body of the Celtic race began to fill a prominent place in general history. About 390 B. C., according to what is little more than a historical tradition, vast hordes of Celts, under their leader Brennus (a word probably equivalent merely to general or king), poured into Italy and sacked Rome, from which they were driven by Camillus. About the same period others appeared along the lower Danube, and succeeded in the establishment of an enduring power there. From this colony many formidable armies went out to carry devastation through Thrace, Macedonia, and Greece. In 280 B. C. one of these, under another Brennus, poured its overwhelming numbers into the kingdom of Ptolemy Ceraunus, defeated and killed that monarch, overran Thessaly, entered central Greece at Thermopylæ, and reached Delphi with the intention of destroying it, when they were at last successfully opposed and driven back. They founded at the same time a kingdom in Thrace, which remained for many years a formidable power, but was finally destroyed by the Thracians around it.—From the same branch of the Celts which sent out these armies (a branch often called the Illyrian Celts from the district, Illyricum, in which their place of settlement was subsequently included) sprung also another offshoot. This consisted of an army which, about the time of the expedition of the second Brennus, crossed the Hellespont into Asia Minor, and appears to have overrun much of the peninsula, until at last the invaders were compelled to confine themselves to the region called after them Galatia. This was successfully held by them, and they established there one of the most enduring of their kingdoms, in which they long preserved many peculiarities of the race.—In the earliest writings the Celts had been called *Κέλται* (*Celtæ*); but as they became better known to the Greeks and Romans, the names *Galli* and *Galatæ* (*Γαλάται*) were more commonly applied to them, these being probably nothing more than corrupted forms of the original word. The names were for a long time used indiscriminately of all the race; but gradually their application was limited—*Galli* (Gauls) signifying those who lived in Europe; *Galatæ* (Galatians), those who settled in Asia Minor; while the name *Celtæ* gradually disappeared. The looseness with which ancient writers use the word *Galli*, employing it now to denote a Teutonic, now a Celtic people, and generally understanding it to mean any northern barbarians, whoever they were, is perhaps the greatest cause of our inability to trace with exactness the gradual decline of the Celts before the advance of other races. Their career after the various wanderings and settlements we have noticed becomes inextricably involved with that of other peoples; and all that can be affirmed with certainty concerning them is the fact that they were gradually absorbed into the Roman,

Germanic, and mixed races that overran Europe during the centuries which followed the beginning of the period of authentic history. In this way they became merely an element in the formation of the nations now populating the European continent, and as a distinct power entirely disappeared from all the region they once had occupied. But although they no longer form an independent nation or people, there remain in the British isles, and in a district of Brittany in France, descendants of the race who retain many of its prominent characteristics, and who continue to make use of different dialects of the ancient Celtic languages. In Wales, Ireland, and the Scottish highlands are found the most marked and distinct types of these; while but a short time has passed since the dying out of a branch of the Celtic race in Cornwall. (See BELGÆ, CELTIBERIAN, CIMBRI, CIMMERII, and GAUL.)

CELTS, Languages and Literature of the. The various families of the race described in the preceding article termed themselves Celts (pronounced Kelts, for in all their languages and dialects the letter C was always hard, and K was absent from their alphabets). Omitting Spain and the north of Italy (the so-called Celtic plain, whose inhabitants became thoroughly Romanized, and of whose ancient literary remains in their own tongue there are no specimens existing), it may be stated generally that two distinct languages were spoken and written by these people, each divided into several dialects. These two languages are still living, spoken and written. They are: 1, the Breton (Breizad), including the Welsh, the Cornish, which has become extinct only within the memory of men, and the Bas Breton, now spoken in the western half of Brittany in France; and 2, the Gaedhlic (Gaelic), which includes the speech of the Scottish highlanders, of the aboriginal Irish, and of the Manx. To avoid confusion, it must be understood that the Welsh call their own language, not Welsh, but Cymraeg (a term perhaps related to the ancient Cimmerian and Cimbric); and it is only in speaking English that they ever accept the name of Welsh at all. Their language is still to be heard commonly spoken throughout the principality, having held its ground better than any of the other Celtic tongues. The other Cymric language, the Bas Breton, is retiring by degrees before the French, and now exists as a living tongue only in that western region of Brittany which the French call *la Bretagne bretonnante*. As for the other family of Celtic languages, it is properly termed the Gaelic; but the Scottish highlanders call it the Erse (pronounced Erish), that is, Irish. The Irish themselves, however, speak of it only as the Gaelic. This is one and the same language, only varying slightly from Caithness to Kerry. The course of ages has introduced some dialectic differences; but even at the present day the speech of the highlanders of Argyle is as

readily understood in Donegal as that of Kerry or Cork. The language of the Isle of Man differs slightly from all these, but in its roots and general structure it is the same. The Celtic languages, then, distribute themselves into the Cymric and the Gaelic. —The **BAS BRETON**, even within its limited range, has four distinct dialects, those of Tréguier, Léon, Vannes, and Cornouaille; in each of these there are remains existing, in the shape of ballads and romantic or fairy legends. Modern scholars connected with that portion of France, especially the count de la Villemarqué, have done much for the preservation of these singular literary relics of a bygone civilization. There are also dictionaries and grammars: students may consult Le Gonidec, *Dictionnaire breton-français et français-breton*, with a valuable introduction by La Villemarqué (2 vols. 4to, St. Brieuc, 1850); also the dictionary of the dialect of Vannes, by M. Leide, published in 1774. Rostrenen published both a dictionary and a grammar of his native tongue, so far back as 1734. But the most indispensable aid to investigation, not only as to the Breton but as to all other Celtic tongues, is the work of J. C. Zeuss, *Grammatica Celtica, e Monumentis veteribus tam Hibernicæ Lingvæ quam Britannicæ, necnon e Gallicæ prisicæ Reliquiis* (2 vols. 8vo, Leipsic, 1853). For the general character of the literary remains of Brittany, see La Villemarqué, *Barzaz-Breiz* (popular songs printed in the original, with a French translation). All the four dialects of the Bas Breton have been more modified by the Latin than other Celtic tongues, owing to the length of Roman domination. It employs Roman letters, some of which (*a, b, d, e, f, g, h, i, l, m, n, o, p, r, s, t, u, v*) sound as in the ancient Latin, others (*k, w, z*) as in English, two (*j* and the combination *ch*) as in French, and the combination *c'h* like the German *ch* (strongly guttural); *l* and *n* are sometimes what the French call *mouillé*, and *n* is sometimes nasal; *w* is also used as a vowel; the diphthongs are genuine and distinct. Some initials of nouns and of verbs are altered after the finals of the preceding words, viz.: *b* to *v* and *p*, as *bâz* (Lat. *baculus*), *ar vâz*, the stick; *k* to *g, c'h*, as *ki* (*canis*), *ar c'hi*, the dog; *cur* (*curia*), *eur ger*, a city; *d* to *t, z*; *gw* to *kw, w*; *m* to *v, mamm* (*mater*), *ar vamm*, the mother; *p* to *b, f*, as *penn*, head, *tri fen*, three heads; *t* to *d, z*; *s* to *z*. The definite article has three forms, *ann* before vowels and before *d, n, t, al* before *l, ar* everywhere else; the indefinite article also varies, *eunn, eul, eur*, in the same positions as the definite. Both are thus used in the singular and plural sense. The genitive is denoted by *eûz*, the dative by *'d*, in both numbers. The plural is made by suffixing *ou* or *iou* (*avêl-ou*, winds; *brêzel-iou*, wars), or *ien, ed, en* (*kaneri-en*, singers; *lôen-ed*, animals; *stêred-en*, stars). Irregular are: *Breizad*, plural *Breiziz*; *askourn*, bone, *askern*, bones; *mâb*, son, plural *mipien*. There are two genders, masculine and feminine. The

comparative degree is formed by *oc'h*, thus, *kaeroc'h*, more beautiful; the superlative by prefixing the article, thus, *ar c'haera*, most beautiful. The numerals are: *unan*, 1; *daou*, 2; *tri*, 3; *pevar*, 4; *pemp*, 5; *c'houec'h*, 6; *seiz*, 7; *eiz*, 8; *nôo*, 9; *dêk*, 10. The ordinals are made by suffixing *ved* (*trived*, third, &c.); these are irregular: *kenta*, first; *eil*, second. The personal pronouns are *mé*, I; *té*, thou; *hen*, he; *hi*, she. The terminations of the verbs are: *ann* for I, *ez* for thou, the radical for he, she, it, *omp* for we, *it* for you, *ont* for they; thus, *rô-ann*, *rô-ez*, *rô*, *rô-omp*, *rô-it*, *rô-ont*—I give, thou givest, he, she, it gives, we, you, they give. The past tense is formed by *iz*, the future by *inn*, &c. Each verb is preceded by the particle *a* before nouns and pronouns, by *é* (or *éz*, *éc'h*) before adverbs. There are three auxiliary verbs, viz.: *béza*, to be; *kaout*, to have; *ôber*, to do. There are some specific prefixes. The syntax is free, with some anomalies; thus, the third person singular of a verb may be joined to the first and second personal pronouns, as *mé arô*, which is *I gives*, instead of *give*. The structure of Breton poetry is generally in tercets or triads, as in the kindred language of Wales. The principal supernatural agents in the popular poetry of Brittany are the dwarfs and the fairies. The common appellation of these elfish beings is *korrigan*, whether masculine or feminine, from *kor*, little (diminutive, *korrik*), and *gan* or *gwen*, genius. The goddess Koridgwen is said by the Welsh bards to have had nine attendant virgins, called the nine Korrigan. This also was the name of the nine priestesses of the isle of Sein. We may refer here, as characteristic examples, to several of the ancient poems collected and translated by La Villemarqué, especially "The Prophecy of Gwenchlan," "The Submersion of the City of Is," "The Changeling," and "The March of Arthur." "The Plague of Elliant" and the "Tale of Lord Nann and the Fay," as preserved until this time, retain the technical bardic form, which was alliterated and arranged in strophes of three lines. This "Lord Nann," which is said to date from the 5th or 6th century, commences thus:

Lord Nann and his bride, both plighted
In youthful days, soon blighted,
Were early disunited.

Of snow-white twins a pair
Yostreen the lady bare,
A son and daughter fair.

"What cheer shall I get for thee,
Who givest a son to me?
Say, sweet, what shall it be?"

"From the forest green a roe,
Or a woodcock from where, I trow,
The pond in the vale lies low?"

"For venison am I fain,
But would not give thee pain
For me the wood to gain."

But while the lady spoke,
Lord Nann took his lance of oak,
And mounting his jet-black steed
Rode forth to the wood with speed.

When he gained the greenwood shade,
A white hind from the glade
Fled, of his lance afraid.

Swift after the hind he flew;
The ground shook 'neath the two,
So swiftly on they flew,
And late the evening grew.

It ends in this gallant huntsman coming "under the ban of a Korrigan," and the death of himself and his wife, from whose grave sprang forth "two spreading oaks." As a specimen of the Bas Breton tongue itself, we give the following from the tale of *Koadalan* (dialect of Tréguier): "Neuzé a krogas ann aotro enhan hag a savas gant-han en er, uhel, uhel. Diskenn a eure gant-han e-kichenn ur c'hastell-kaer, en un âle vraz, lec'h ma oe souezet o welet skrivet war delio ar gwez: Ann hini a antré aman, na sorti kén. Ma teuas c'hoant d'ehan mont-kuit, met penoz? Antren a reont ho daou bars ar c'hastell; debri hag eva a reont, ha goudé koan, a kousk mad en ur gwélé-plun." Which is thus translated: "The knight then took him up, and lifted him very high into the air. He descended near to a fine castle, in a grand avenue, where Koadalan was much surprised to see written on the leaves of the trees, 'He who enters here never goes away again.' Which gave him a desire to go at once; but how? They enter together into the castle; they eat together; and after supper Koadalan sleeps well in a bed of feathers." On the whole it may be said that the relics of Bas Breton literature are entirely confined to childish fairy tales and stories of romance, offering little or nothing of the antiquarian historic interest which is found in the remains of the Cymric tongues of Wales and in the Gaelic of Ireland.—THE WELSH (*Cymraeg*). The alphabet of this language consists of thirteen simple and seven double consonants and seven vowels, with numerous diphthongs and triphthongs. The letter *c* always has the sound of *k*; *ch* is sounded gutturally, as in the Scottish word loch; *dd* is equivalent to *th* in English; *f* has the sound of the English *v*, *ff* of the English *f*, *ll* a peculiar sound similar to that of the French *l mouillé*, *u* and *y* that of the Italian *i* or English *ee*, and *o* of *oo* in fool. The accent is always on the ultimate or penultimate syllable. Initial consonants are changed by-declension and by the effect of preceding words; e. g.: *tâd*, a father; *ei dâd*, his father; *ei thâd*, her father; *vy nhâd*, my father. Thus *p* is changed into *b*, *mh*, and *ph*; *t* into *d*, *nh*, and *th*; *b* into *f* and *m*; *d* into *dd* and *n*, &c. There is one article, which is not declined, but varies according to the initial letter of the following word. Substantives are declined by prepositions, by terminations, and by changes in their radical vowels; e. g.: *perth*, bush, plural *perthi*; *bwa*, bow, plur. *bwaau*; *tyrfu*, throng, troop, plur. *tyrfaedd*; *march*, horse, plur. *meirch*; *ffordd*, road, plur. *ffyrdd*; *alarch*, swan, plur. *elyrch*; *mab*, son, plur. *meibion*; *nant*, brook, plur. *nentydd*; *maen*, stone, plur. *meini*. There are but two genders,

masculine and feminine. Adjectives are formed from substantives, and verbs by means of the terminations *aïd, gar, ïg, ïn, lyd, og, and us*. The comparative is formed by the ending *ach*, the superlative by *af*; e. g.: *du*, black; *duach*, blacker; *duaf*, blackest. The feminine adjective is formed from the masculine by softening the initial letter, and also by changing the radical vowel. The verb has no present tense, to express which the future is used, or the substantive verb *wyo* (I am) with the infinitive. There are, however, imperfect, perfect, pluperfect, and future tenses, which are formed, both in the optative and indicative moods, by endings and changes of vowels without auxiliary verbs; e. g.: *caron*, I loved; *cerais*, I have loved; *carason*, I had loved; *caraf*, I shall love. Each tense has three persons both in the singular and plural; e. g.: *caron, carit, carai, carem, carech, carent*. The passive voice is wanting, and is expressed by a peculiar circumlocution. There are several irregular verbs besides *wyo*. The adjective is usually placed after the substantive, but is often placed before. The numerals are: *un, dau* or *dwy, tri* or *tair, pedwar* or *pedair, pum, chwech, saith, wyth, naw, deg*. The personal pronouns are: *mi*, I; *ti*, thou; *ev*, he; *hi*, she; *ni*, we; *chwi*, you; *hwy* or *hwynt*, they. "The language," says Ferdinand Walther, "has great power, simplicity, and precision. It is very rich especially in roots, and has a remarkable capacity to express an entire abstraction in a single word."—The literature of the Cymri has laid claim to a very ancient origin, but modern criticism shows that even the earliest Welsh writings are subsequent to the Christian era. The first eminent bard of whose period of existence we have a distinct record was Myrddin, the bard of Prince Emrys, the first Merlin of romance, who flourished about 450. Aneurin, identified by some with the Gildas of ecclesiastical history, Taliesin, prince of bards, Llewarch Hen, and Myrddin Wyllt or Merlin the Wild, belong to the 5th and 6th centuries; of them all numerous poems remain. The most gifted among more modern bards was perhaps Dafydd ap Gwylem (1295–1356), sometimes called the Ovid of Wales, the poet of love and nature. A volume of translations from his writings has been published in London (1834). Huw Morris (1622–1709) wrote songs, carols, and elegies, and sometimes violent political satires. The last remarkable poet of Wales, Goronwy Owen (1722–1780), died poor in New Brunswick, and his productions, including the *Cwydd y Farn* ("Day of Judgment"), regarded as the finest work of genius in the language, were first printed in 1819. The earliest Welsh prose literature is the triads, said to be of druidic origin, a sort of maxims in triplets, each setting forth a historical event or a moral principle. Next is the "Chronicle of the Kings of the Isle of Britain," supposed to have been written by Tysilio in the 7th century, and said to be the

original of the chronicle of Geoffrey of Monmouth. It was continued to the year 1152 by Caradwg of Llancarvan, whose work is also in existence. The "Code of Howel Da," of the 12th century, is also an important literary monument, as is the "Biography of Gruffydd ap Cynan," of the 15th century. The *Mabinogion* ("Juvenile Diversions"), made accessible to English readers by the translations of Owen Pugh and Lady Charlotte Guest, is a collection of Cymric legends and fairy stories of unknown antiquity, but committed to writing in the 14th century. "The Sleeping Bard," written about 1700 by Elis Wyn, a moral and religious allegory, divided into the "Vision of the World," "Vision of Death," and "Vision of Hell," is a work of great originality and power; it has been translated into English by George Borrow (London, 1860). The first translation of the New Testament into Welsh was made by William Salesbury (1597), and the first translation of the whole Bible was completed by William Morgan and published in 1588. Considerable bodies of Welsh emigrants have brought their native language to the United States, and there are communities in which it is the prevailing tongue. Welsh periodicals, newspapers, and religious tracts and books are also published in the United States for the use of citizens of Welsh origin. A convenient Welsh grammar for students is that of William Spurrell (London, 1848; 2d ed., 1853).—Of the Cornish branch of the Cymraeg, now extinct as a spoken language, the indefatigable Zeuss, in the *Vocabularium Cornicum* of his *Grammatica Celtica*, has given almost all that is now known. There is also the "Ancient Cornish Drama," edited and translated by Edwin Norris.—THE GAELIC. For this language, spoken in Scotland and Ireland, there are many grammars and dictionaries. Among these may be mentioned the dictionary of Edward O'Reilly (4to, Dublin, 1817), a book which has lately acquired much additional value by a new edition and supplement prepared by the eminent Gaelic scholar John O'Donovan, editor of the "Four Masters." This work may be taken for the present as the nearest approach to a standard dictionary of the language. Of grammars there are also several; of which we name that of Neilson, that of Owen Connellan (Dublin, 1844), and the "College Irish Grammar," by the Rev. Ulick J. Burke, of St. Patrick's college, Maynooth (Dublin, 1856). The literary and historic remains of this language are very voluminous, and have been industriously collected, translated, and annotated by modern scholars, both in Scotland and in Ireland. They consist mainly of annals, laws, and genealogies, but with a large infusion of romantic and fairy tales like those of Brittany. The Gaelic speech has varied considerably from age to age; and a great portion of the industry of its professors has been expended upon the "glosses," that is, partial translations of sentences and phrases, from the Latin, or into the

Latin, made by monks in all the monasteries of Europe for many ages. The spoken language of Connaught or of Inverness gives but little help in these researches; for the speakers of this language could not understand an ancient manuscript of the 12th century if read to them. The alphabet of the language consists of 18 letters, named from trees (*ailm*, elm; *beithe*, birch; *coll*, hazel, &c.). The letters *k*, *g*, *v*, *x*, *y*, and *z* are wanting. Many consonants are not pronounced. The pronunciation varies in different periods and localities. The indefinite article, the neuter gender, and a special form for the present tense of the verbs are wanting in Gaelic. There are two declensions and two conjugations. A peculiar metaphony is much used, as: *fear*, a man; *fir*, of a man; *fhir*, O man! The system of prefixes and suffixes resembles that of the Semitic tongues. The numerals are: *aon*, a 1-aon, 1; *dhà*, a 2-dhà, 2; *tri*, 3; *ceithir*, 4; *cuig*, 5; *coig*, 5; *sè*, 6; *seachd*, 7; *ochd*, 8; *naoi*, 9; *deich*, 10; *aon deug*, 11, &c.; *fichead*, 20; *deich ar fhichead*, 30 (10+20); *da fhichead* 40 (2×20), &c.; *ceud*, 1,000, &c. The nominative plural is formed by adding *ean*, as *clàr sairean*, harpers. The sexes are distinguished by three methods: by different words, by prefixing *ban* or *bain* for females, and by an adjective. The personal pronouns are: *mì*, *mhi*, I; *tu*, *thu*, thou; *e*, *se*, he; *i*, *si*, she; *sinn*, we; *sibh*, you; *iad*, *siad*, they. The relative pronouns are: *a*, who, which; *an*, whose, and to whom; *na*, that which; *nach*, who not. The possessives are: *mo*, my; *do*, thy; *a*, his, her; *ar*, our; *bhur*, *ur*, your; *anjam*, their. The interrogatives are: *co*, who; *cia*, which; *ciod*, what. The indefinite pronouns are: *càch*, the rest; *cuid*, some; *eile*, other. Among the verbs are: *phaig mi*, I wrapped; *phaig thu*, *phaig e*, &c.; negatively, *do phaig mi*, &c. *Abair*, to say; *thubhairt mi*, I have said; *air radh*, said; *ag radh*, saying. Verb to be: *ta mi*, I am; *ta thu*, thou art; *ta e*, he is; *ta sinn*, we are, &c.; *am bheil mi*, am I; *cha'n eil mi*, I am not. Among the prepositions are: *a*, *as*, of; *ag*, at; *air*, on; *an*, in; *bhàrr*, off; *car*, during; *do*, to, of; *eadar*, between; *gu*, till; *mar*, as, like; *o*, from; *rè*, during; *re*, *ri*, *ris*, to; *trid*, through, &c.—The best authorities to be consulted as to the actual literary remains which now exist in the Gaelic are the *Grammatica Celtica* of Zeuss, before cited, and the works of the late Eugene O'Curry and John O'Donovan, both members of the royal Irish academy. O'Curry has left a specially valuable book of reference for Gaelic students, "Lectures on the MS. Materials of Ancient Irish History" (Dublin, 1861). This elaborate work contains almost all that is now accessible concerning the writings still existing in the Gaelic tongue, with catalogues and descriptions of the "lost books," which appear to have been very numerous. But still many works have not been lost; and the zeal of antiquarian societies, the archaeological, the Celtic society, and others, has presented to the public a

whole library of Gaelic lore, generally with translations and careful notes by John O'Donovan. The most voluminous of these is the "Annals of the Four Masters," in 7 vols. 4to, a book which was compiled in its present form so late as the beginning of the 17th century, but which was necessarily founded upon chronicles of very remote times. This book, with its notes, together with the publications of the Celtic and Ossianic societies and the series of volumes put forth by the archaeological society, may be said to furnish all the information which is extant on the subject. The chevalier Nigra, late Italian minister at Paris, is one of the most zealous Celtic students. His *Glossæ Hibernicæ Veteres Codicis Taurinensis* (Paris, 1869), from Gaelic MSS. and glosses found in the monastic libraries of Milan and Turin, has been highly praised by Celtic scholars. It ought to be mentioned that the work of Zeuss was revised and almost reconstructed after his death by H. Ebel; and it is now the most authoritative book of reference for students either of Gaelic or Cymric.

CEMENTATION, a chemical process chiefly employed in the manufacture of steel and of porcelain glass. To convert wrought iron into steel, the bars are selected with care, broken into convenient lengths, and placed in layers in pots, mixed with and surrounded by charcoal. These pots are subjected to an intense heat, by which the carbon gradually penetrates the iron, and combines with it. Different views are entertained with regard to the formation of cement steel, but it is most probable that the carbonization of the iron bars, when heated in powdered coal with the exclusion of air, takes place by means of cyanogen compounds which are formed in the state of gas, rather than by a direct reaction of carbon or carbonic oxide gas. The American bank note company cement their engraved plates in carbon obtained from fine ivory turnings. Bottle glass is cemented with gypsum powder or sand, to form Réaumur's porcelain.

CEMENTS, certain substances which by their interposition cause the surfaces of solid bodies to adhere together or to unite, the action being either mechanical or chemical, or both. The history of the fabrication of cements, like that of many other arts, reaches so far back into the early ages that it is impossible to ascertain with much exactness where it was first skilfully practised. The ancient Egyptians 4,000 years ago possessed the knowledge not only of making building mortar, but of mixing earthy materials which would set and harden under water. In the construction of the pyramid of Cheops, a cement made of Nile mud and gypsum is believed to have been used. Many of their sculptures in bass relief were executed in cement, and examples are still preserved of Egyptian ceilings in painted stucco of a date much earlier than Solomon's temple. The pictures in relief which have been discovered in the excavations at Nineveh were mostly executed in alabaster;

but the Babylonians, not having such materials, covered their bricks with plaster, on which they made their designs. It was upon the "plaster of the wall" of Belshazzar's palace that the mystic hand traced the fatal letters. Under Nebuchadnezzar Babylon became the first city in the world, and mortars and cements of various kinds, of a bituminous and earthy character, were used in enormous quantities in the construction of edifices and public works. The Greeks gave the subject much intelligent attention, as is evidenced by the chemical composition and state of preservation of mortars and cements which have been found in their ancient temples; and it is a matter of history that in the earlier development of the architectural and engineering arts by the Romans, the Greeks were often consulted by them. The Romans, however, attained to the greatest distinction for the magnitude and durability of their works. They prepared an excellent cement for hydraulic purposes, which they used in making concrete with broken stones for the construction of various piers and harbors on the Mediterranean. They early became acquainted with the properties of pozzuolana, which mixed with burned lime gave them a hydraulic cement that can scarcely be said to have been since excelled. The mole or breakwater of Pozzuoli is one of the monuments of the durability of their hydraulic structures. It was composed of 24 arches, sustained upon piers, built of brick faced with stone, and held together with cement made of pozzuolana and lime. Thirteen of the piers are still above the water, although they were built more than 1,800 years ago. The arched construction was for the purpose of preventing a collection of sand behind the mole. Vitruvius, in his work *De Architectura*, says: "There is found in the neighborhood of Baia, and the municipal lands lying at the foot of Vesuvius, a kind of powder which produces admirable effects; when mixed with lime and small stones it has not only the advantage of giving great solidity to common buildings, but possesses the further property of forming masses of masonry which harden under water."—Cements may be divided into those which are chemical and those which are mechanical, or into the stony and the resinous and glutinous. The stony cements may be again subdivided into those which harden on exposure to the air, such as common building mortar; those which harden when immersed in water, as the hydraulic cements; and those which harden principally by combining with water, as gypsum and gypseous cements. Common building mortar is made of lime and sand. The preparation of lime by calcination from limestone, chalk, marble, and other forms of carbonate of lime, is treated of in the article **LIME**. Many kinds of limestones contain carbonate of magnesia as well as carbonate of lime, and are called dolomitic limestones. When the proportion of carbonate of magnesia is 46 per cent., the stone is called dolomite,

and has been pronounced unfit for making building mortar. It does not become so hot in slaking nor set so soon as pure lime; but those who use it assert that in time it becomes harder. Some of the best lime in this country is made from stone obtained along the Hudson river, much of which is almost pure dolomite. Before mixing with sand, the lime is slaked, a process that requires to be carefully performed in order to secure good results. Three volumes of quicklime moistened with one of water slakes with much violence and the evolution of heat, which often reaches 300° F. If enough water is used to cover the lime, it will be made to boil. Slaked lime is a hydrate of the protoxide of calcium, and is two and a half or three times the volume of the quicklime used. All the water used in slaking should be added at once. Less than is required to convert all the lime to a hydrate will cause a granular powder to be formed, which is of inferior value. After the slaking is completed the mass should be allowed to lie one or two days before it is made into mortar. In the south of Europe it is often put in boxes and kept for months, a practice which is thought to increase its power of conferring hydraulic energy to pozzuolanas. When used, the slaked lime should be made into a creamy paste by the addition of about an equal quantity of water. The quantity of sand to be added depends upon the use which is to be made of the mortar, and also upon the quality of the sand. In order to prevent shrinking, there should not be much more lime paste than is sufficient to fill the void spaces between the particles of sand. Coarse sharp sand will therefore take more lime than that which is fine, and will in time generally become harder. For bricklaying and the rough or foundation coat of wall plastering, the proportions vary from two to three parts of sand to one of lime paste. In the rough coat in wall plastering about one sixth part by measure of cows' hair is mixed, to aid in binding. Mortar may be mixed by hand, in which case a common hoe is the implement generally used. A mill, however, mixes the materials more thoroughly, and when a large quantity is required will repay the outlay. A common pug mill, such as is used for grinding clay for brick, answers the purpose very well, or one having a pair of heavy rollers moving round an axis in a circular pan. A form used in Europe is a conical mill, which empties into a trough or tube in which a spiral band wound round a shaft revolves, while it mixes the mortar and carries it to the end, when it is delivered into tubs. The setting and hardening of mortar are two distinct processes. Setting is caused partly from the adhesion that takes place between the particles of sand and lime, and which is no doubt increased by incipient chemical action, partly from the formation of more or less crystalline hydrate, and probably to some extent by evaporation. The hardening of common building mortar consists in the

slow conversion of the hydrate of lime into carbonate and silicate, and the deposition of crystalline hydrate, and also in the cohesion that naturally results from the long-continued apposition of particles of matter with one another. There has been a long and an unsettled controversy among chemists, architects, and engineers in regard to the changes which take place in mortar after it has been laid in walls exposed to the air, some maintaining that the hardening is chiefly caused by the conversion of the hydrate of lime into carbonate; others believing that it is principally due to the slow formation of a silicate; and others again that it is due to both these changes, and also to the crystallization of hydrate and consequent packing of void spaces aided by the force of cohesive attraction. From the investigations of Prof. F. Kuhlmann of Lisle, in regard to the action of alkaline silicates upon limestones and chalk, it is probable that the lime after becoming carbonated is susceptible of combining with a certain portion of silica, if this is present in a soluble condition in combination with an alkali, and forming a silico-carbonate of lime. Petzholdt examined several old mortars. Some that were 300 years old yielded lime water when digested in fresh water, thus showing the presence of caustic lime. Some portions effervesced in cold dilute hydrochloric acid, yielding in a short time a stiff jelly, thus revealing the presence of a soluble silicate of lime. He moreover found that in similar mortars, those which were 300 years old contained three times as much soluble silicate of lime as those which were only 100 years old. These experiments not only show that silicification takes place in building mortar made of lime and sand, but that it takes place in a pretty constant rate of progress, which would appear to be somewhat independent of the degree of carbonization attained by the lime.—Hydraulic cements are used in the construction of fortifications, breakwaters, aqueducts and reservoirs, canals, foundations of bridges, and other works of military and civil engineering, as well as in the construction of cellars and cisterns. The useful property which they possess of rapidly setting when immersed in water, and of continuously hardening under the same influence, chiefly results from the strong affinity of caustic lime for silica and alumina, and from the affinity the resulting compounds have for water, and their insolubility. They are divided into two principal classes, natural and artificial cements. The former are entirely made from certain rocky strata or earthy substances, without any admixture of foreign material; while those which are artificial are made by combining earthy substances with caustic lime, and sometimes small portions of an alkali. Certain geological formations contain beds which are composed of such proportions of lime, alumina, silica, the alkalies, and a few other bodies of less consequence, that after they are calcined insoluble compounds are formed on the addition of water.

Other formations exist, of a less calcareous constitution, which need the addition of caustic lime to enable them to perform the same or similar reactions; and there are others which contain too much lime to be capable of being used for hydraulic cement, but which may be employed in making what is termed hydraulic lime. The stone from which hydraulic cement is made in the United States is found in stratified rocky beds of aqueous deposits, lying principally in strata of the Silurian system connected with the Appalachian chain of mountains. It is an argillaceous limestone, which yields on calcination the proper proportions of lime, alumina, and silica to unite with water and form a hard substance without slaking or expanding, and also to indurate continuously in consequence of other chemical reactions. The Silurian system, in the classification of the New York geologists, lies in strata in the following order:

SILURIAN SYSTEM.	Upper.	Lower Helderberg.	Lower Helderberg.
		Salina.	Saliferous.
		Niagara.	Niagara. Clinton. Medina. Onida.
	Lower.	Hudson.	Hudson river. Utica.
		Trenton.	Trenton. Black river. Birdseye. Chazy.
		Potsdam.	Califerous sandstone. Potsdam sandstone.

This formation covers a large space in Canada, N. of New York, about the size of that state, and also a large area N. W. of Lake Ontario. In the United States it covers about half of the state of New York and the western part of Vermont, whence it extends in a belt S. W. through eastern New York, and through the states of New Jersey, Pennsylvania, Maryland, Virginia, and East Tennessee. It also appears in Middle Tennessee and Kentucky, and covers a vast area W. and N. W. of Lake Michigan, 600 m. in longitude and from 200 to 500 in latitude. Most of the hydraulic cement in New York is obtained from beds in the Trenton and lower Helderberg formations. In Ohio beds are found in the upper coal measures, and in Illinois in the lower carboniferous formation and in the Niagara group. In Canada there are beds in the saliferous group. Only a few layers of these groups are used, most of them either containing too little or too much lime. Those of the Trenton group which furnish hydraulic cement extend from Vermont, in a narrow belt, southward through the eastern tier of counties in New York, passing into Orange county at Newburgh; thence through Sussex and Warren counties, New Jersey, into the state of

Pennsylvania, appearing in Berks, Chester, Lancaster, and York counties, and passing through Maryland into Virginia, where they are found in Rockingham, Augusta, Rockbridge, Roanoke, and other counties. The tenticulite, or water limestone of the lower Helderberg formation, however, furnishes most of the hydraulic cement that is used in the United States. Large deposits are found in Oneida, Onondaga, Madison, Niagara, Erie, Ulster, and Sullivan counties, New York. The largest development of the manufacture has taken place in Ulster county. The deposits there occupy a narrow belt in the valley of the Rondout creek, along the line of the Delaware and Hudson canal, and pass into New Jersey and Pennsylvania, but have not been found east of the Hudson river. The following table, made from a larger one in the work of Gen. Q. A. Gillmore "On Limes, Hydraulic Cements, and Mortars," gives analyses made by Prof. E. C. Boynton of four samples of hydraulic limestone, and the localities from which they were taken:

CONSTITUENTS.	Shepherdstown, Va.	Akron, Erie co. N. Y.	High Falls, Ulster co., N. Y.	
			Layer 1.	Layer 2.
			Carbonate of lime.....	58.25
Carbonate of magnesia.....	11.16	19.26	14.48	85.10
Silica, clay, and insoluble silica..	17.84	83.80	89.74	19.64
Alumina.....	4.60	3.96	6.00	7.52
Sulphuric acid.....	.74	.50	.66	.64
Chloride of sodium & potassium.	3.26	6.15	7.42	4.10
Peroxide of iron.....	1.70	.88	1.44	2.38
Hygrometric water lost at 212° F.	.20	.14	.24	.18
Total.....	97.75	100.32	100.72	100.28

The limestone from which cement is made, as has been intimated, varies considerably in quality even in the same locality, the difference depending much upon the relative position of the layer from which it is taken. The nearer it lies to those strata that are decidedly calcareous, the more it approaches in character what is called a rich lime, slaking and expanding more or less. Again, when the more highly argillaceous strata are approached, and the deposit contains less lime, it loses energy and capability of hardening. Some of the stones require greater time for calcination than others, from 20 to 40 hours being the range. If the temperature is raised too high, the silicate is partially fused and the property of setting under water destroyed. It is therefore evident that such stones should not be burned together, although they may be mixed afterward. Careful inspection is not always sufficient to detect the difference, nor is chemical analysis always to be relied on, although it is quite probable that those limes which contain much alkaline silicates should not be so highly calcined as others. Trial kilns capable of burning from 100 to 300 lbs. should be frequently used. In preparing hydraulic cement

for the market, similar kilns to those used for calcining common limestone are employed, and the processes are also similar. The perpetual flame kiln, or the draw kiln, such as is used on the continent of Europe, particularly the one invented by Friedrich Hoffmann of Berlin, is preferable. Kilns which are charged with alternate layers of fuel and limestone do not furnish so equable or controllable a degree of heat, and it is more important to secure this condition in calcining hydraulic limestone than in making quicklime. The process of calcination is described in the article LIME. After burning, the stone is passed through a crushing mill and reduced to small pieces of the size of beech nuts, and is then finely pulverized by ordinary millstones. The crushers in general use are capable of preparing for the mill about 250 bbls. per day each; and one millstone will grind about 10 bbls. per hour. One cubic yard of stone from the quarry yields about 9 bbls. of ground cement, of 300 lbs. each. In Ulster county it is packed in barrels as it comes from the spout. The color of most of the hydraulic cement made in this country is a lighter or darker drab, the depth of hue depending principally upon the amount of oxide of iron which may be present. It will be observed from the table that the hydraulic limestones of Ulster and Erie counties, N. Y., as well as the one at Shepherdstown, Va., contain a large proportion of carbonate of magnesia. This might be regarded as a defect from what has been said of the effect of the presence of magnesia in common lime; but the case is altered in respect to hydraulic cements, and they are considered by Vicat and Marshal Vaillant, as well as by MM. Rivot and Chatoney, as being superior for hydraulic purposes on this account. When hydraulic cement is to be used, it is made into a paste with water, but no definite rules as to the proportion can be prescribed; the best plan being to add just that quantity which will form a paste of such a consistence as can be manipulated with facility by the trowel. When the cement is used to form grout for filling in walls, it requires to be made thinner. The setting and hardening of hydraulic cement are processes not so distinctly separated as they are in the case of common building mortar. The setting and much of the hardening take place simultaneously, or rather the setting and hardening are mostly one and the same process; and with some cements it takes place almost immediately, further hardening proceeding slowly by cohesion, and by further chemical changes that have been commenced. The time varies with the kind and quality of the cement, some kinds taking not more than ten minutes, while others require more than as many hours, to become hard enough to fracture. MM. Rivot and Chatonay state that in calcination of an argillaceous limestone, when it has been just sufficient to expel the carbonic acid from the carbonate of lime, there will be formed a silicate and an aluminate of

lime, SiO₂, 3CaO, and Al₂O₃, 3CaO, which on the addition of water become hydrates, SiO₂, 3CaO, 6HO, and Al₂O₃, 3CaO, 6HO. But if the calcination has been effected with intense heat, so as to produce partial vitrification, the reaction will become more complex, silicate of alumina and silicate of lime being formed first; after which, on the addition of water, decomposition takes place with the formation of hydrosilicate and hydroaluminate of lime, each containing three equivalents of water instead of six. From the fact that increased hydraulicity is conferred on some earths which are used in making hydraulic cement by mixing them with lime that has been slaked a long time and exposed to the air, and therefore partially reconverted to a carbonate, it would appear that double decomposition is often favorable to the silicification of the lime; or in other words, that on quitting its union with carbonic acid it more readily combines, in consequence of being in a nascent state, with the silica, which on leaving its union with an alkali is also in a nascent condition. What influence oxide of iron may have on the hardening of cements is still a matter of discussion. Experience sometimes seems to favor the idea that it is beneficial in ultimate hardening; but very hard cements have been made which contained scarcely a trace of iron, and the subject must be considered as involved in doubt.—The hydraulic cements principally employed in Europe are the Roman, Portland, Medina, Mulgrave, and those made on the continent from pozzolana, trass, santorin, and Teil lime. Modern Roman cement, so called because of its similarity to the old Roman cement, is principally made in England and France. The English article is made from nodules, or septaria, found in the Kimmeridge and London clays. The first modern Roman cement was made by Mr. Parker of London, who patented his process in 1796; it consisted in calcining the septaria stones nearly to the point of vitrification, and then crushing and grinding them to powder without admixture of any other material, the product being therefore a natural cement. Roman cement is also made at Boulogne from nodules of septaria lying in the same geological formation, and does not essentially differ in quality from that made in England. Roman cement is now made in England from a clay shale found above the chalk formation in the isle of Sheppey and the isle of Wight. In Germany Roman cement is also made from limestones of a similar character. All the Roman cements contain a notable quantity of oxide of iron, as will be seen in the following table of analyses by Michaelis:

CONSTITUENTS.	1.	2.	3.	4.
Lime.....	58.88	55.50	47.89	58.88
Magnesia.....	5.00	1.73	24.26	2.25
Silicic acid.....	28.83	25.00	5.50	23.60
Alumina.....	6.40	6.96	1.50	7.24
Oxide of iron.....	4.80	9.63	20.80	7.97

No. 1 is Roman cement from the Rüdersdorf limestone; 2, from limestone shale from the isle of Sheppey; 3, from limestone forming the under bed of the lead ores at Tarnowitz; and No. 4 is from Hausbergen limestone. Portland cement, an artificial compound, so named from its resemblance to Portland stone, was first manufactured by Joseph Aspdin of Leeds, England. His method was, according to his letters patent, to pulverize limestone and burn it in a kiln; then to add an equal weight of clay and thoroughly knead the mixture with water to a plastic mass, which was dried, broken in pieces, and again burnt to expel all the carbonic acid. Since that time, however, great improvements have been made in its manufacture, both in England and on the continent. To obtain the best results, it has been found that the lime should be in a state of carbonate when it is mixed with the clay, and therefore, on account of greater facility and cheapness, chalk is employed instead of limestone. Two methods are practised, one in England and the other in Germany, which are somewhat different. In England the wet method is followed, which consists in mixing the materials together with water and grinding them to a pulp, which, after evaporation to the proper degree of stiffness, is made into balls or bricks, which are dried and then calcined to near the point of vitrification, after which they are ground in a mill. The proportions of the ingredients are from 65 to 75 per cent. of chalk to 25 or 35 per cent. of clay. In Germany the dry method is preferred, which consists in first drying the materials and reducing them to powder separately, after which they are mixed with water in the proper proportions, and made into bricks, which are then dried, calcined, and ground, as in the English method. The Germans also add a certain quantity of alkali, either soda or potash, depending upon the quantity which may already be contained in the clay, but enough to bring the amount to 3 or 4 per cent. of the whole, for the purpose of forming a soluble silicate to act upon the lime in setting; and sometimes a small amount of finely pulverized sand or quartz rock is added. In making mortar of Portland cement Mr. Lipowitz, a German manufacturer, recommends the use of about 100 parts of cement to 44 parts of water, but the proportions are subject to variation. Analyses of four varieties of Portland cement made in England and Germany are given by Michaelis:

CONSTITUENTS.	1.	2.	3.	4.
Lime.....	59.06	62.81	60.33	55.06
Silicic acid.....	24.07	23.22	25.98	22.92
Alumina.....	6.92	5.27	7.04	8.00
Oxide of iron.....	3.41	2.00	2.46	5.46
Magnesia.....	0.82	1.14	0.23	0.77
Potash.....	0.73	1.27	0.94	1.13
Soda.....	0.87		0.90	1.70
Sulphate of lime.....	2.85	1.90	1.52	1.75
Clay sand.....	1.47	2.54	1.04	2.27
Total.....	100.20	99.55	99.84	99.06

Nos. 1 and 4 are English Portland cements, No. 2 made at Stettin, and No. 3 at Wildau. It will be remarked that in these instances the English cements contain the largest proportions of alkalis. In France a similar method is employed. The hydraulic lime of Saint-Leger is made of four parts of chalk to one of clay. The ingredients are ground together in a mill with water, and when sufficiently firm the mixture is made into bricks, which are calcined in a common kiln, mixed with coke, a lower degree of heat being employed than in burning Portland cement. Gen. Pasley is regarded as the founder of artificial cement manufacture in England. In 1826 he made a cement by burning the river mud from the Medway with limestone or chalk. This mud, on account of its argillaceous composition, as well as from the presence of sodium salts, is well adapted to the purpose; but other materials are now used, such as marls mixed with clay, and generally the deposits at the deltas of rivers. A natural Portland cement is made at Boulogne, from a layer of Kimmeridge clay which lies about 160 ft. below the strata in which the septaria nodules are found. It is burned and ground without the addition of lime or any other material. In burning this earth the best results are obtained by bringing it to a white heat, so that vitrification begins to take place. It has a greater specific gravity than English Portland cement, and requires less water for making into paste than either that article or the Boulogne Roman cement; and it also sets more slowly, requiring from 10 to 20 hours. The reason of its taking less water is explained by the theory of MM. Rivot and Chatoney that where cements are calcined at a high heat silicate of alumina and silicate of lime are formed, which on the addition of water undergo decomposition with the formation of aluminate and silicate of lime, containing each three instead of six equivalents of water, which is the case when a heat only sufficient to drive off the carbonic acid of the carbonate of lime is employed; and the decomposition which must take place before the final hydration also explains the slow setting. Pozzuolana is found not only at the foot of Mt. Vesuvius, but in various places in Europe: in Sicily, in Mauritius, in Guadeloupe and Martinique, and in several places in France. It is mixed, without calcination, with caustic lime. Sometimes, however, the lime is allowed to stand for several months after slaking before being used, and this practice is said in some instances to increase the hydraulic energy of the product, probably in consequence of the partial recarbonization of the lime facilitating the process of silicification which takes place between the lime and the alkaline silicates contained in the volcanic pozzuolana. A substance of volcanic origin called trass is found in the valley of the Rhine, which has long been much used, especially by the Dutch engineers, for hydraulic works in Holland, and

the Romans also employed it many centuries ago. It possesses qualities nearly identical with Italian pozzuolana, and is treated with lime in the same manner. It is of a grayish color, and lies in beds composed of fine particles and small lumps. The following table showing the chemical composition of pozzuolana and trass is taken from Wagner's "Chemical Technology: "

CONSTITUENTS.	Pozzuolana.	Trass.

A hydraulic lime obtained at Teil, in the department of Ardèche, France, has been found to possess properties which eminently fit it for use in marine constructions, as it sets and hardens well in salt water. As analyzed by Prof. Rivot, it has the following composition:

THE UNBURNED STONE.	THE BURNED LIME.
Lime..... 46.8	Lime..... 78.29
Oxide of iron..... 0.7	Oxide of iron..... traces
Silica, quartz sand, and clay..... 15.0	Silica..... 18.20

—Various methods are employed for ascertaining the hardness and tensile strength as well as the power to resist pressure. The apparatus of M. Vicat for testing the hardness and determining the time of setting employs a pointed pin, which, by means of a suitably adjusted frame, is driven against the surface of a prepared brick of cement with any given force, and which is determined by different weights which are used as the motive power. The tensile strength is found by fastening each end of a brick in a suitable clamp or socket, and suspending it with a weight attached at the lower end. The force required to produce fracture in this case will represent the power of cohesion attained by the particles of the brick. The power of resisting pressure is found by placing a prepared brick, having perfectly plane sides, under a weight which may be increased at pleasure. The crushing and tractile force necessary to overcome the resistance of the cement may be found by mathematical calculation, by supporting a brick edge-wise and applying a weight in the middle, which will exert a crushing force at the upper, and a tractile force at the lower edge. The jetties which form the harbor at Port Said, the Mediterranean terminus of the Suez canal, were constructed of blocks of concrete made of hydraulic lime from Teil mixed with beach

sand, and exposed for several weeks to the action of the air. This has also been used with good results in the harbors of Marseilles and Toulon, and at various other places, in both fresh and salt water. The piers enclosing the harbor at the ocean terminus of the North sea canal of Holland are laid in Portland cement, and the same material enters into the structure of the Cherbourg breakwater. The foundations of Fort Tompkins and Fort Richmond in New York harbor are composed of concrete made of hydraulic cement, sand, and fragments of granite, in the proportion of one part of cement to three of sand and five of granite. Exterior stucco work is now to a great extent made of hydraulic mortar.—For further information in regard to the details of the technical manipulation employed in manufacturing, using, and testing hydraulic cements and mortars, see "Practical Treatise on

Calcareous Mortars and Cements," by L. J. Vicat (London, 1837); "Observations on Calcareous Cements," &c., by Major Gen. Sir C. W. Pasley, K. C. B. (London, 1847); Henry Reid's treatises on Portland cement and on concrete (London, 1868 and 1869); the practical essay of A. Lipowitz on Portland cement (translated by W. F. Reid, London, 1868); the work of Dr. W. Michaelis, *Die hydraulischen Mörtel* (Leipsic, 1869); Gen. Q. A. Gillmore's treatise on "Lime, Hydraulic Cements, and Mortars" (New York, 1872); and "Report on the Hydraulic Lime of Teil," by Leonard F. Beckwith, C. E. (New York, 1873).—The following table of the composition of ancient mortars, with the names of the analysts, is taken from Mr. Reid's treatise on concrete, and will be found interesting to peruse in connection with the various theories of the hardening of mortars:

—The mastics and other oily cements of London have nearly gone out of use on account of their want of durability. They were compounds of lime, sand, litharge, and linseed oil. Gypsum and gypseous cements are much used for internal plastering and decoration. The rapidity with which plaster of Paris sets when mixed with water makes it an article of great value. The gypseous cements mostly used in England are Keene's and the Parian. The former is obtained by recalcining plaster of Paris which has been slaked with a saturated solution of alum and water, and again slaking it with a saturated solution of borax. Bituminous cements are employed as substitutes for flagging in paving streets, and to protect the extrados of arches from the effects of water; and for this they have much utility, because in all new masonry there are movements which fissure the coatings made in hydraulic cements, so that it is almost impossible to render them impermeable to water, and the elasticity of

bituminous cements is well calculated to overcome the defects of the more unyielding stony compounds and render them particularly serviceable in making repairs. They are made from natural asphaltum, which is mixed with chalk or carbonate of lime, or with hydraulic cement. A cement which is made in Silesia for covering roofs is composed of Portland cement, coal or wood tar, and a small portion of sulphur. Among the resinous cements are Varley's, which is made by drying by means of a red heat 16 parts of pulverized whiting, and when cold stirring it in a melted mixture of 16 parts of black resin and one of beeswax. Singer's electrical and philosophical apparatus cement consists of 5 lbs. of resin, 1 lb. each of beeswax and red ochre, and two tablespoonfuls of plaster of Paris, melted together. The ochre and plaster should be previously calcined, and added after the other ingredients are melted. Lapidaries' cement for holding gems while they are being cut is made of resin and red ochre or

Spanish brown, melted together and tempered with a little beeswax and tallow. Opticians' cement, for a similar purpose, the fixing of glasses for grinding, is made of sifted wood ashes and melted pitch. White lead cement, made by grinding linseed oil varnish and white lead together, is used for repairing fractured bodies of all kinds, but requires a considerable time to harden. Plumbers' cement is made of two parts of brick dust and one of black resin melted together. Iron rust cement is made by mixing 50 or 100 parts of iron filings with one part of sal ammoniac. When used it is moistened with enough water to form a paste. The subsequent rusting and the consequent packing of the joints to which it may be applied gives it a particular value. Sometimes clay may be added to the mixture with advantage. A solution of shellac in alcohol, added to one of isinglass in proof spirit, makes a cement which has considerable power to resist the action of moisture. Common glue, melted with half its weight of resin and a small quantity of red ochre to impart body, is used in cementing hones to their frames. A strong cement for stoneware is made by boiling the cheese of skimmed milk in a large quantity of water, and incorporating the solution with quicklime in a mortar. It may be used cold, but it is better to warm it. It joins earthenware, marble, or any kind of stone so that the seam can scarcely be discovered. A cement composed of from four to six parts of potters' clay and one of iron filings, with enough linseed oil to form a paste, makes a cement which is often used in stopping cracks in steam boilers. In the distillation of caoutchouc, the residue left in the retort, when again mixed with the distilled oil, or caoutchoucine, forms an elastic cement which is much used by shipwrights; and another tenacious cement is made by dissolving one part of caoutchouc in four parts of coal tar, adding two parts of shellac, and heating the mixture in an iron vessel.

CEMETERY (Gr. *κοιμητήριον*, a sleeping place), a place appointed for the burial of the dead. In rude states of society the dead are often buried in any place that may be found most convenient, by the side of some road, or in some vacant spot in the city; but even in very ancient times grounds were often set apart which were especially appropriated for the reception of the dead. The Hebrews had public burial grounds, and their first care upon arriving in a new country was to select a plot and reserve it as a burial place. Every city had one outside of its walls, that of Jerusalem being in the valley of Kedron. Ruins and mummies have been found in Babylonia and Egypt which show that the burial places in those countries in former times were of immense extent. Although the Greeks in later times adopted from Phrygia the custom of burning the dead, yet their custom originally was to provide cemeteries. Among the Romans also the more ancient practice was the appropriation of ground for

interment; and even after incineration had been introduced, the practice continued, and the Appian way was lined with sepulchres as well as with funeral urns. The early Christians would seem to have introduced a somewhat different practice. The laws of the twelve tables had prescribed that the dead should not be buried within the walls of the city. The early Christians, however, erected some of their churches upon plots of ground in which were interred the remains of martyrs, and around others reserved an open space which was consecrated for the reception of their dead. In the middle ages also churchyards were used for cemeteries. Even the churches themselves were occupied in part for tombs, and crypts and vaults were excavated beneath their floors. The church, deriving a considerable revenue from the burial of the dead, inculcated the importance of burial in consecrated ground, over which it retained control. To this day the older churches in large cities are surrounded by graves, and in small towns and villages the burial ground is usually near the church. The increase of population and a better knowledge of the laws of health have in a measure restored the ancient practice, and cemeteries are at the present day generally provided without the limits of all large towns and cities.—There are many cemeteries which are celebrated. Those around the city of Constantinople have become very extensive on account of the practice of invariably opening a new grave for each corpse, it being considered sacrilege to disturb the dead. The practice is also to plant a cypress by the grave of every Mussulman, so that the cemeteries of Constantinople are embowered in forests. Those of Scutari and Pera are the most noted. The cemetery of Pisa in Italy, called the *Campo Santo*, is a beautiful oblong court, 490 ft. long and 170 ft. wide, surrounded by arcades of white marble 60 ft. high, and adorned with ancient Etruscan, Greek, and Roman bass reliefs and other sculptures, and with paintings by the early Italian masters. In its centre is an enormous mound of earth said to have been brought from Palestine during the crusades, and formerly used as a burial ground. This cemetery is the Pantheon of the Pisans, and among its most famous monuments is the tomb of Algarotti, erected by Frederick the Great in 1764. It has given its name to burial grounds throughout Italy. The campo santo of Bologna is one of the finest of them. It is without the city, and was anciently a Carthusian monastery called Certosa, having been consecrated as a cemetery in 1801, when burials within the city were prohibited. The church of the monastery has been preserved, and is adorned with fine paintings. The cemetery occupies the corridors of two of the cloisters of the convent. Niches have been built in the walls for the reception of the dead. There is a large hall in which are placed the busts of those who have been eminent for learning. Some

of the tombs and monuments are of beautiful design, those of Pope Alexander V., Francesco Abbigato, and Sigismondo Malvezzi being especially remarkable. The campo santo of Genoa is about two miles from the city, upon the slope of a hill in the valley of the Bisagno. It is quadrilateral, and upon the sides are terraces, beneath which are excavated the vaults. In the centre is a circular chapel, with a dome supported by 16 Doric columns on each side, of dark Corsican marble. The cemetery contains works by some of the best sculptors of Genoa. It was commenced in 1838, after designs of Resasco, a Genoese architect. There is a curious cemetery near Naples. It is a parallelogram 300 ft. in length, on three sides of which is a lofty wall, and on the fourth an arcade. It contains 366 deep pits, some of which are under the arcade and others in the open space in the centre. Every morning a pit is opened, and in it are deposited all the dead bodies which are brought during the day. At evening a funeral service is performed over the entire number. Of other campi santi the most interesting are at Ferrara, Brescia, Parma, and Verona; and among the more recent and extensive is that of Milan. A campo santo after the plan of that of Pisa has been projected in Berlin, to serve as a royal burying place and to adjoin a new cathedral. Cornelius designed for this some of his most celebrated frescoes, but the building remains unfinished.—One of the acts of the constituent assembly of France in 1791 was to prohibit interments within the limits of cities, and to require the establishment of cemeteries outside of those limits. In 1804 four were authorized, one of which, Père Lachaise (now within the *enceinte*), has become the best known. It was laid out upon the estate called Mont Louis, which was presented by Louis XIV. to his confessor Père de Lachaise. It contains the tombs of many illustrious persons, among which are those of Abé-lard and Héloïse, La Fontaine, Molière, Beaumarchais, Delille, Talma, Bellini, Weber, Laplace, Cuvier, Casimir Périer, Arago, Benjamin Constant, Börne, Royer-Collard, Marshal Ney, the painter David, Sieyès, Barras, Frédéric Soulié, Balzac, and many others. Its highest elevation commands the city on one side and the surrounding country on the other. Its hills and valleys are covered with every variety of column, obelisk, pyramid, funeral vase, and sculptured flowers and garlands. In England the French example has not been followed, and burials are allowed within the limits of cities, sometimes even within churches. In Russia the cemeteries are at a distance from the cities and villages, and planted with pines. In the United States great attention is paid to the embellishment of cemeteries. Many of them are spacious, laid out with taste, and planted with trees. The most noted and beautiful are Mount Auburn near Boston, Greenwood in Brooklyn, and Laurel Hill near Philadelphia. The principal cemeteries in this country will

be described in connection with the cities near which they are situated.

CENCI, Beatrice, a beautiful Roman girl, born about 1583, executed in September, 1599. She was the daughter of Francesco Cenci, who inherited great wealth from his father, the treasurer or minister of finance of Pius V. Francesco was a man of bad character and dissolute habits, but was able through his large fortune to escape the punishment of his crimes. Of the children by his first wife two were murdered. Beatrice was the eldest of the three who survived. His second wife, Lucrezia Petroni, and Beatrice were taken by Francesco to Petrella, a desolate castle among the Sabine hills near the Neapolitan frontier. There Beatrice and her stepmother were subjected to every species of ignominy and insult. It was said that Beatrice was forced by her father to submit to incestuous intercourse. She vainly appealed to Pope Clement VIII. for protection, and then she and her mother resolved to rid themselves of their persecutor. Monsignore Guerra, who afterward became Beatrice's lover, united with them, and they employed two assassins to waylay and kill Francesco as he was returning to Petrella. But the attempt failed. Beatrice and her mother afterward, on Sept. 9, 1598, drugged Francesco, and Beatrice introduced assassins into his room, and he was killed while asleep. One of the murderers made a confession, and Beatrice, her stepmother, and her two brothers were charged with the instigation of the crime and subjected to torture. Lucrezia and the elder brother, Giacomo, admitted their guilt; but Beatrice, though but a girl of 16, long persisted in maintaining her innocence. The Cenci family were connected with the most illustrious houses of Rome, and strong intercessions were made on behalf of the accused. The great advocate Farinacci was heard in their defence. He urged in extenuation of their course the vices and crimes of the murdered man. He succeeded in obtaining the acquittal of the younger brother, Bernardo, his guilt not having been proved; but while the fate of the others remained undecided, the princess of Santa Croce was murdered by her son, and the pope resolved to make an example of Beatrice, Lucrezia, and Giacomo. They were all executed, Beatrice displaying the most heroic courage to the end. In her last will she directed that her property should be appropriated for furnishing dowries to young girls. Her remains were interred at Montorio in the church of San Pietro. The vast estates of the family, including the celebrated villa Borghese, were confiscated and bestowed upon members of the Aldobrandini and Borghese families, relatives of Pope Clement VIII. and the future Paul V. The youth and beauty of Beatrice were so great that her execution sent a thrill of horror through Rome. The people would not believe that she had been guilty, and charged the government with having condemned her in order to obtain

possession of the estates of the Cenci family. The indignation was so strong and so lasting that these estates were finally in part restored to the heirs of Giacomo Cenci. The family assumed the name of Bolognetti in addition to that of Cenci, and for a long time were involved in lawsuits with the Borghese family in regard to the Cenci estates. Muratori's "Annals" is one of the authorities in regard to Beatrice Cenci. Her story is told in an article in the "Quarterly Review" (1858) as derived from a contemporary manuscript; and in the *Storia di Beatrice Cenci*, by Carlo Tito Dalbano (Naples, 1864), the original documents and judicial proceedings which relate to it are cited. De Custine has founded a drama, Guerrazzi a novel, and Shelley a tragedy upon the story. *Il processo criminale della Beatrice Cenci*, by Antonio Torrignani, in refutation of Guerrazzi's historical romance *Beatrice Cenci*, was published at Florence in 1873. The celebrated portrait of Beatrice, which is said to have been painted by Guido Reni immediately before her execution, is in the Barberini palace at Rome. Its authenticity is doubtful.

CENEDA, a town of Italy, in the province and 22 m. N. of Treviso; pop. about 8,000. It is the see of a bishop, and possesses a cathedral, several churches, manufactories of leather, woollens, and paper, and mineral springs.

CENIS, Mont, a mountain between the province of Turin in Italy and the department of Savoie in France, at the junction of the Graian with the Cottian Alps. It is an elevated plateau 6,773 ft. above the sea level, with a peak rising to the height of 11,457 ft. On the plateau is Lake La Ramasse, noted for its fine trout. There is little vegetation, on account of the force of the winds which blow constantly. Over this plateau or neck, formed by a gradual sinking northward from the summit of the chain, is what is styled the pass of Mont Cenis, at some distance from the mountain itself. As a practicable pass from Gaul to Italy it was unknown to the ancients. Two centuries before Christ, Hannibal went past it for 40 m., and is supposed to have crossed the Alps at the Little St. Bernard. It first appears in history as an Alpine pass in A. D. 755, when Pepin led his army against Astolphus, king of the Lombards, in aid of Pope Stephen III. Pepin's son Charlemagne led an army over the same route. In 1174 it was crossed by Frederick Barbarossa. In 1557 the duke of Alva passed over with a Spanish army to quell the revolt in the Netherlands. In 1691, in the wars of Louis XIV., Marshal Catinat led the French army across, and made some improvement in the road; but for centuries it was little more than a mere mule path. In 1803 Chevalier Fabroni, under the orders of Napoleon, began the construction of a carriage road, which was completed in 1810, at a cost of 7,500,000 francs. This highway, 18 ft. wide, extending from Saint-Michel on the western side to Susa on the eastern, would give a distance in a straight line of 30

m., but the windings of the road make it 50 m. An excellent diligence service was established; horses were changed as rapidly as on the best post roads; and at the zigzags, beginning at Lanslebourg on the west side, teams of 16 mules were attached to drag the diligence up the steepest ascents, while many of the passengers dismounted and materially shortened the distance for themselves by walking directly across the long curves. The road was open and safe at all seasons, even in winter, and for many years it was believed to be the only practicable way of crossing the Alps at this important point. Meanwhile railways on either side had reached the foot of the mountains, and about 1861 Mr. Fell, an English engineer, con-

Mont Cenis Railway.

ceived the idea of overcoming by steam transit the gradients of the pass, by applying a principle patented more than 30 years before by Charles Vignolles and John Ericsson, and first tried by them on the Cromford and High Peak railway in England. In 1865 Fell obtained from the French and Italian governments a grant to lay down a railway on Napoleon's Mont Cenis carriage road; it was constructed at a cost of £8,000 per mile, and opened in 1868. The main feature of his plan was the addition of a third central rail, raised a foot above the others, and, by means of brakes and levers, strongly gripped by horizontal driving wheels, thus enabling trains to traverse curves of short radius, and safely to ascend and descend gradients of 1 in 15, and even 1

in 12. From Lanslebourg the track reaches the summit, 4,460 ft. above Saint-Michel, in six zigzags, with a gradient of 1 in 15 to 1 in 12½, in a distance of 6¼ m. At the summit there is a nearly level run of 5 m., and then begins the descent on the Italian side to Susa, over a line extended to a length of 20 m. by a series of zigzags so continuous that the view changes every moment. The train slides down by its own momentum, and all the mechanical power is applied to the centre brake which checks and regulates the speed. But as this road superseded Napoleon's carriage road, on which the greater part of the line was laid, so it in turn has been superseded by the Mont Cenis tunnel railway, completed in 1871. While it was in use travel was occasionally suspended by snow and floods, though wherever there was danger from avalanches the line was thoroughly protected by covered galleries. The idea of a tunnel through the Alps was conceived more than 40 years ago. In 1832 Joseph Medail, a peasant of Bardonecchia, presented to the king of Sardinia a plan for connecting Piedmont and Savoy by a railway tunnel from Bardonecchia to Modane; and in 1843 this plan, accompanied with many particulars, was approved by the chamber of agriculture and commerce at Chambéry. In 1845 the Sardinian government invited the engineer Maus and the geologist Sismonda to prepare designs for making a tunnel through Mont Cenis; and Maus, turning his attention to creating a machine for cutting rock rapidly, was ready in 1849 to present to the commission at Turin a plan for tunnelling the Alps. The defects of his plan were the cost, want of ventilation, and waste of motive power. Daniel Colladon of Geneva discovered more perfect means of ventilation, and also of transmission of force; and an English engineer, Thomas Bartlett, invented an ingenious machine for rapidly perforating rocks. These two inventions, modified by the engineers Sommeiller, Grandis, and Grattoni, with further plans of their own, were presented to the Sardinian parliament in June, 1856, and experiments for perforating the Alps were authorized and begun at Coscia. These were so successful that parliament approved the project of the Alpine tunnel, and the work was inaugurated by the king of Sardinia, who fired the first mine Aug. 31, 1857. In October and November piercing by hand was begun at the two extremities, and a large force was also employed in the construction of roads, water channels, magazines, offices, storehouses, and houses for workmen. The waters of the Arc on the north side, and of the Melezet on the south, were utilized for the hydraulic machines which compressed the air supplied to the tunnel. In January, 1861, the perforating machines, worked by compressed air, were introduced on the south side at Bardonecchia, and in January, 1863, on the north side near Modane. The work was carried on successfully night and day till Dec. 26, 1870, when

the two bodies of workmen met and the tunnel through the mountain was complete. The progress of the perforation, nearly 8 m., was as follows: on the Bardonecchia side, from 1857 to 1861, by hand, 2,379 ft.; from 1861 to 1871, by machines, 20,851; on the Modane side, from 1857 to 1863, 2,366; from 1863 to 1871, by machines, 13,886; total for the two entrances, 39,482 ft. The mechanical means were water-column compressors, pump compressors, and perforating machines. The number of workmen employed was 1,500 in winter and 2,000 in summer at each entrance. When Savoy in 1860 was annexed to France, an agreement was made between the French and Italian governments by which Italy was to execute the entire work within ten years, receiving from France about 32,000,000 francs for one half of the expense. The total cost of construction was about 75,000,000 francs, or \$15,000,000. The Mont Cenis tunnel (improperly so called, as it is 16 m. from the mountain) was opened for railway travel Sept. 17, 1871. The elevation of the southern entrance above the sea is 4,237 ft.; of the northern entrance, 3,802; of the culminating point, 4,247. The tunnel is broad enough for two double lines of rails. The railway does not run in a straight line through the tunnel; the entrances are left open only for ventilation, and the tracks are laid in junction tunnels, on the south of the length of 2,484 ft., and on the north of 1,488. (See TUNNEL.)

CENOBITE (Gr. *κοινός*, common, and *βίος*, life), a person who lives in community with others under a common rule. The term is usually applied to the members of some religious association who live in common. In very ancient times the Brahmans of India formed such associations. St. Pachomius established a *canobium* or monastic institution on Tabennæ, an island of the Nile, in the year 340. Those members of religious orders living in cloisters and convents were called cenobites, as distinguished from the anchorites who lived in solitude.

CENSER, a vessel for burning and wafting incense, used in the celebration of religious rites by the ancient Hebrews, Greeks, and Romans, and still retained in the Roman Catholic church. The Hebrew censer appears to have been a sort of chafing dish, with or without handles, which the high priest carried into the sanctuary or placed on the altar of incense. That used in the Catholic church, also called a thurible, is a vessel shaped much like a goblet, with a perforated lid, swung by long chains, and carried by an acolyte.

CENSOR (Lat. *censere*, to estimate), the title of Roman magistrates of high dignity and great influence, instituted in the year 443 B. C. The office was vested in two persons, originally elected for five years, from and by the patrician order; but later changes introduced by the dictator Mamercus, 433 B. C., and afterward, reduced the term of the office to 18 months, and made it attainable by plebeians, of whom

Rutilus, who had also been the first dictator of that order, was the first elevated to this dignity (351); and in 131 even both censors were plebeians. They had all the ensigns of consular dignity except the lictors, and wore a robe of scarlet. Their office was to take the regular census and keep the rolls of all Roman citizens, to distribute them according to orders, tribes, &c., to value, register, and tax their property, to control public morals and manners, to fill remarkable vacancies in the senate, to choose the *princeps senatus*, to manage the farming of the revenues, customs, and salt monopoly, to contract for repairs of public buildings and roads in Rome and Italy, &c. They had the right of punishing moral and political transgressions committed by citizens of distinction with marks of ignominy, by expulsion from the senate, and even by degradation from a higher to a lower order; for which punishments the ill-treating of members of their families, extravagance, and the pursuit of mean professions, were regarded as sufficient reasons; but their decisions were subject to an appeal to the assembly of the people, and themselves to its jurisdiction. The dignity of censor was regarded as most honorable, and originally only those were eligible who had passed through all other offices. The emperors assumed it under the title of *morum præfecti*; Decius desired to restore it independently under a particular officer. The brother of Constantine the Great was the last censor.

CENSORINUS, a Latin grammarian and chronologist of the 3d century. He wrote a treatise upon accents, cited by Cassiodorus, but lost. Only a fragment of his work *De Metris* is extant. He is known principally by a curious work entitled *De Die Natali*, treating of the generation of man, his natal hour, the influence which the genii and stars exercise over his destiny, and of the climacteric periods of his life. He also discusses music, religious rites, and matters relating to astronomy, chronology, and cosmography. By this work the commencement of the era of Nabonassar and other dates have been fixed, and Censorinus has therefore been named by Scaliger *eximius et doctissimus temporum vindex*. The first edition of Censorinus is in quarto, without date, place, or printer's name; the second was that of Bologna, in 1497; the last is a German edition, by Gruber, in 1805.

CENSORSHIP OF THE PRESS, a regulation by which books, pamphlets, and newspapers are subjected to the examination of certain civil or ecclesiastical officers, who are empowered to authorize or forbid their publication. Such a regulation was suggested by Plato, and an informal censorship existed in the times of Greece and Rome. Thus all the copies of the works of Protagoras were burned at Athens by sentence of the areopagus, because he had expressed doubts concerning the existence of the gods. Satirical works and writings on magic were often condemned to the flames by the Roman

emperors, and Diocletian ordered the sacred books of the Christians to be burned. After the church acquired a share in the civil power, it induced the state to condemn heretical books, and the writings of Arius were burned by edict of Constantine. Subsequently there were numerous enactments by popes and councils against the works of heretics, sanctioning the principle that books objected to by the church should be suppressed. This principle was maintained throughout the middle ages, authors often as a voluntary act of respect submitting their works before publication to the judgment of the higher clergy. The first eminent instance of this kind was that of Autpert, a Benedictine monk, who in 768 sent his "Exposition of the Apocalypse" to Pope Stephen III., begging him to publish the work and make it known. The invention of printing and the increasing number of books called forth new and stricter prescriptions of censorship, and there still remain copies of books printed in 1479 and 1480 which are accompanied with solemn approbations and attestations in their favor. In 1486 Berthold, archbishop of Mentz, issued a mandate forbidding the publication of any work in the German language unless it should be first read and approved by one of four censors whom he appointed. Shortly after Pope Alexander VI. addressed a bull to the archbishops of Cologne, Mentz, Treves, and Magdeburg, according to which no book should be printed without special express license from the clergy. Finally, in 1515, the council of the Lateran, assembled at Rome, decreed that in future no books should be printed in any town or diocese unless they were previously inspected and carefully examined by the bishop of the diocese or his deputy, or by the inquisitor of the diocese or his deputy, or if at Rome by the pope's vicar and the master of the sacred palace. Every work which was approved was to be countersigned by the hand of the censor, and any publication not thus countersigned was to be burned and its author or editor excommunicated. Thus was a general censorship of the press consummated by the Roman Catholic church, which has since been enforced by that church in countries where it has had the power. Its "Index of Prohibited Books" was begun by the council of Trent, and has been from time to time republished and enlarged. It has also an "Index of Expurgated Books."—In countries where the reformation prevailed, the censorship was not abolished. Licensers of books were appointed in England, who were for the most part bishops; and in the reign of Charles I. complaints were laid before the house of commons against Archbishop Laud and his associates, because, as was alleged, it was impossible to obtain from them permission to publish a book written against popery. A general system of censorship was established by a decree of the star chamber, dated June 11, 1637, which remained in force during the civil war, and was confirmed by an act of par-

liament in 1643. It was against this act that Milton wrote his "Areopagitica: a Speech for the Liberty of Unlicensed Printing." "Paradise Lost" itself was in danger of being suppressed because the simile of Satan compared with the rising sun, in the first book, was supposed to contain a political allusion. Parliament took several measures against "scandalous, seditious, libellous, and unlicensed pamphlets." In 1653 the council at Whitehall ordered that no person should print any matter of public news or intelligence without leave of the secretary of state. The licensing system, and with it the censorship of the press, was abolished in England in 1694 in the reign of William and Mary, but the question of its revival was agitated in parliament some time later.—A general censorship of the press existed under the old French monarchy. Originally in the hands of the bishops, it passed by degrees to the doctors of the faculty of theology; but this faculty becoming divided into parties on matters of controversy, the chancellor of the kingdom took the censorship from it in 1653. He appointed four royal censors with an annual stipend to examine all works without distinction, and no writing could be printed or sold, and no dramatic piece performed, unless approved by one of them. At the outbreak of the revolution the censorship was abolished and entire liberty of the press proclaimed, but in the reign of violence which followed there was no safety for obnoxious journals or writers. Napoleon during the consulate limited the freedom of the press to works of a certain size, but subjected newspapers and pamphlets to a strict inspection. By a decree of the council of state in 1810, a complicated system of censorship was revived in France. Even after a book had been examined, approved, and printed, it could be seized by the minister of police and its sale stopped, a memorable instance of which was the destruction of the whole first edition of Mme. de Staël's *De l'Allemagne*. After various modifications of the censorship, Charles X., upon coming to the throne, abolished it altogether, but soon after suspended the liberty of the periodical press. This was one of the causes of his fall in 1830, after which the press once more became free. Under the empire of Louis Napoleon the Parisian newspapers were subjected to strict supervision and occasional suppression; and the republic of 1870 maintains the same system. A general censorship of the press is maintained in Russia. By the Spanish constitution of 1837 the previous censorship was abolished, and all Spaniards may print their thoughts freely, subject only to the laws. The determination of offences committed by means of the press belongs to juries impanelled for that purpose. In Switzerland since 1830 no censorship has existed, but the liberty of the newspaper press is very much restricted by laws. By the constitution of the kingdom of Greece of 1827, the Hellenes have the right of publishing freely their thoughts, abstaining

however from violations of decency, from personal calumny, and from attacking the principles of the Christian religion. In Sweden, Norway, the Netherlands, Belgium, and Denmark, no authoritative censorship exists, but upon those who offend through the press penalties of various degrees of severity are imposed. These penalties are most rigorous in Denmark. The liberty of the German press has been even more unsettled than the political government of Germany. While the emperors of the house of Austria had vainly sought to establish uniform rules to check the press in all the states, Frederick the Great granted uniform liberty to the press in his dominions, "because it amused him." During the ascendancy of the French republic the press was arbitrarily checked in most of the states, though it was free in Bavaria, Holstein, and occasionally in Hesse and Mecklenburg. The censorship was subsequently abolished in some of the smaller states, as Nassau, Würtemberg, and Saxe-Weimar; but a congress of the German rulers, assembled at Carlsbad in 1819, extended it over all printed publications under 20 sheets. Permission also had to be obtained for selling foreign books. The French revolution of 1830 prompted the German people to demand complete freedom from the censorship, except in cases specified by the diet; but though liberal regulations were obtained, they were upheld only a short time, and there was a gradual reaction toward the decree of Carlsbad. The movements of 1848 everywhere established the freedom of the press; and though the subsequent reaction curtailed it here and there, the censorship has since remained abolished. In the United States of America there never has been a censorship of the press. There are laws against publications of a scandalously immoral character, but in general the only restraint upon printing or circulating any class of books is found in the public sentiment.

CENSUS, an official enumeration of persons and their property, generally with such facts as tend to show their moral, social, physical, and industrial condition. In the Pentateuch the enumeration of the people is repeatedly enjoined, and the most ancient statistical record of the kind is that of Moses in the wilderness. There is record of a census in China ordained by the emperor Yee 2042 B. C., and of one in Japan under the mikado Sujin in the last century before Christ. Under the constitution of Solon, the citizens of Athens were divided and registered (*τιμήματα, τέλη*) into four classes, according to the amount of their taxable property or income. The Roman census originated in the distribution of citizens into classes effected by Servius Tullius, the sixth king of Rome, in a most solemn manner on the Campus Martius, where every citizen had to appear, and to declare upon oath his name and dwelling, the number and age of his children, and the value of his property, under the penalty of having his goods confiscated, and of being scourged

and sold for a slave. The whole population was divided into six classes based upon property qualifications, each comprising a number of centuries. Augustus, who had the population numbered, enlarged the scope of the census, and improved the mode of taking it.—In the 16th century the practice of keeping church registers of births, marriages, and deaths, out of which grew the modern systems of recording the movements of the population, came into use. No exact popular enumerations were made in the 17th century, but in the 18th great progress was made in the development of statistical science. In Russia partial censuses were taken by order of the government in 1700, 1704, 1705, and 1710. In 1719 a commission was organized by Peter the Great to visit the principal provinces of the empire for the purpose of making a general census. The commission was charged to ascertain the number of peasants, mechanics, domestics, and persons without regular employment. The whole population was returned excepting females, who were omitted because the census was taken solely for purposes of revenue and military conscription. Females, however, were subsequently included, but returned with less exactness than the males. In 1722 insane and infirm persons without means of subsistence were included in the enumeration, and it was ordered that a census should be taken at intervals of twenty years. Accordingly enumerations were taken in 1742, 1762, 1782, and 1796. The taking of the census was eventually vested in the central administrations of the provinces, which were held responsible for its correctness. As early as 1802 a "central bureau of statistics" was organized under the direction of the ministry of the interior, to which the results of the statistical inquiries of the several departments of the government were transmitted, and which published from time to time statistical exhibits of the public administration, population, territorial extent and subdivision, agriculture, commerce, and industry of the empire. The central bureau of statistics was reorganized in 1852, and again in 1858, under the name of "central statistical commission," which has charge of the preparation and publication of statistical information of various kinds; but one of its chief functions is the enumeration of the population. Censuses were taken in 1812, 1815, 1834, 1851, 1858, and 1867. Formerly the range of inquiries was very limited, but in the most recent censuses has been extended so as to include the legal population by sexes; the number of houses in towns, and of estates in villages and country; and the number of churches and chapels, benevolent institutions, schools, fairs, markets, post stations, and manufacturing establishments. The census is taken by means of printed schedules which are distributed and collected by the local administrative authorities. The time in which the census is to be taken is fixed by the government, a longer time being

allowed for the Asiatic than for the European provinces. The digesting and publication of the returns devolve upon the central statistical authorities. A separate mode of taking the census prevails in the province of Finland, which has a special statistical bureau. It is taken by the civil authorities in conjunction with the clergy, and relates exclusively to population.—In Prussia census taking dates from the time of Frederick William I., by whom measures were instituted to ascertain the number of the population. This was done through officers of the government, not by an actual enumeration, but by calculations based on various data. This imperfect system was greatly improved by Frederick II. From 1748 to the close of the century an enumeration of the inhabitants, under the direction of the superior authorities of each province, was made annually, except during a few years when it was prevented by war. In 1805 a central bureau of statistics was organized, which has existed with progressive changes in its constitution to the present time. It embraced within its functions general statistics; births, marriages, and deaths; schools and churches; medical statistics; and statistics of mechanical trades and manufactures. At first inquiries into these various subjects were made annually; but after 1820 annual inquiries were made only as to the general movement of the population and births, marriages, and deaths, information relating to the other subjects being collected once in three years. Upon the establishment of the customs union in 1834, the existing system of triennial population censuses was adopted. At first the inquiries related to the actual population, according to the age, sex (arranged in yearly classes), birthplace, and civil condition; mental and physical disabilities; school attendance, religion, immigration, and emigration. In 1840 the enumeration was made by names, which resulted immediately in a large increase in the population returns. In 1846 the number of families was determined; in 1849 the distribution of the population by habitations; in 1858 the number of persons of each sex between 17 and 45 years of age was returned in five classes; in 1861 the unmarried and widowed were specially classified, and inquiry was made as to the language spoken, and the social condition and occupation of the people. The Prussian census is taken by civil officers in December, on one day, by means of printed schedules. Besides the census, extensive statistical information relating to a great variety of subjects is prepared and published by the statistical bureau, and by the several departments of the government. In most of the minor German states the census is taken triennially under the regulations of the customs union, and differs but little from the Prussian system. In Bavaria, besides the triennial census, a more extended one is taken every 12 years. The first census of the new German empire was taken Dec. 1, 1871.—The first census in Aus-

tria was taken in 1754, and was followed by a general enumeration of the population at triennial periods. Until 1857 this information was obtained for military purposes; but in that year a new census law was made which provided that a census should be taken every six years by the civil authorities, and should embrace an enumeration of the population and the useful domestic animals. Printed schedules, with detailed instructions, are distributed by municipal and administrative officers, to be filled up by the heads of families, owners of tenement houses, and those in charge of convents, schools, and public institutions. Any person refusing to furnish the required information is liable to punishment by fine and imprisonment. The inquiries relate to the composition of families, including servants, age, sex, names, and titles, civil state, social condition, religion, occupation, marriages, births, and deaths, and the number of cities, towns, hamlets, villages, dwellings, and renters. The number of Austrian subjects living in foreign parts is obtained through the imperial legations. The census returns are tabulated and published by the "central statistical commission," under whose direction many other statistical inquiries are carried on.—In Sweden the science of statistics has been more particularly cultivated than in any other country. As early as 1686 a law was promulgated requiring the clergy to keep registers of marriages, legitimate and illegitimate births, deaths, persons removed from or settled in the parishes, and of the inhabitants arranged by habitations and households. This information was tabulated, and published for the first time in 1746 by the Stockholm academy of sciences, for the purpose of showing the total population of the realm. After 1749 annual consolidated returns were made by the clergy. In addition, general censuses were taken at irregular intervals from 1749 to 1775, and subsequently at quinquennial periods. These censuses exhibited the number, sex, age, and occupation of the inhabitants; the number and sex of married and single persons, widows, and widowers; the number of blind, deaf and dumb, and insane; of pupils attending schools; of persons not belonging to the established church; and the number of inmates of hospitals, asylums, and prisons. To these was added in 1804 the number of vaccinated persons; in 1821, the number of first, second, and third marriages, the age of the married, the number of legitimate children deceased when less than a year old, and the number of immigrants and emigrants; in 1831, the number of marriages, births, and deaths among all classes, the number of legitimate and illegitimate children, still-born, and deceased in their second and third year, by months; the number and age of persons deceased in hospitals, asylums, and prisons; and the movement of the population not belonging to the established church. The census is taken every five years, by means of

printed schedules, through the joint agency of the civil authorities and the clergy. The most recent was taken Dec. 31, 1871. A separate census is taken of the Laplanders and Finns. The governors of provinces are required to prepare every five years statistical summaries upon a variety of subjects not included in the census. A central statistical bureau was organized in 1857, charged with the superintendence and publication of population and other statistics. There has been a decennial census in Norway since 1815, the last having been taken Dec. 31, 1865. Inquiries are made as to age, sex, civil state, number of families and inhabitants, useful domestic animals, and the territorial area of each district. Annual exhibits are made up of births, marriages, and deaths; of commerce and navigation; of the administration of justice; and of the population suffering from physical or mental disabilities.—General censuses were taken in Spain in 1787 and 1798. The next one was taken in 1857, and was followed by another in May, 1860, which is the last general census. The population was, however, determined by calculation in 1867. The inquiries relate to name, sex, age, birthplace, civil condition, occupation, physical disabilities, degree of education, school attendance, habitation, and the distribution of population in cities, towns, villages, and hamlets. The census is taken in one night, by government officials charged with the collection and consolidation of the returns.—In Denmark a general population census was taken every five years between 1840 and 1860. It is now decennial, the last having been taken Feb. 1, 1870. The movement of the population is ascertained by means of civil registers.—The first direct and simultaneous enumeration of the people throughout the kingdom of Portugal was made Jan. 1, 1864, in pursuance of a law passed the preceding year, providing for a decennial census. The enumeration, made by means of household schedules, was completed in one day, and comprised inquiries as to sex, age, civil condition, occupation, nationality, habitual or accidental sojourners, and the present and absent.—In Switzerland census taking was instituted about the middle of the 18th century. In 1860 a law was enacted prescribing a decennial census for the whole federation, and in the same year the first census under the law was taken. The inquiries include sex, age, civil condition, origin, birthplace, domicile, religion, language, physical disabilities, immigration, the distribution of real property, and the number of families and of habitations and other buildings.—Belgium ranks among the first nations of the world in completeness of its national statistics. In 1841 a central commission was established by royal decree. A general census was taken in 1846. In 1856 a new law was passed providing that a general census should be taken every ten years, which should exhibit the actual as well as the legal population. The prescribed inquiries include surnames and Chris-

tian names, sex, age by year and month, birthplace, civil condition, occupation, domicile, and town and country population. In the second census, taken under this law in 1866, comprehensive inquiries into the agricultural, mining, and manufacturing interests of the kingdom were made. Three schedules, printed in the French, German, and Flemish languages, were distributed and collected in one day respectively by special census agents. The statistics of schools and public institutions were taken by means of special schedules. The census of the army was taken by the military authorities. Refusal to furnish information to the census agents was punishable by fine and imprisonment. In 1858 a special census of deaf mutes and blind was taken. The census returns, together with the yearly abstracts from the civil registers, and the results of special inquiries, are prepared for publication by the central statistical commission. A census was taken Dec. 1, 1870.—In the Netherlands the census is taken decennially, the last dating Dec. 31, 1871. It embraces inquiries as to name, sex, age, place of birth, civil state, profession, occupation, or condition, physical disabilities, religion, number of families and habitations. The army and navy, inmates of hospitals, almshouses, prisons, schools, and public institutions generally, are separately enumerated.—The present bureau of statistics in Italy was organized in 1860, with the well known statistician Dr. P. Maestri as chief. Provision was made for decennial censuses, the first of which was taken in 1861, and the latest Dec. 31, 1871. It was taken by municipal and administrative officers, in one day, by means of previously distributed schedules, embracing inquiries designed to show the actual population by age, sex, civil state and domestic relations, families, habitations, nativity, religion, language, physical and mental infirmities, occupation, emigration and immigration, aggregations of population by communes, and aggregations of habitations. The census returns were revised by local commissioners appointed throughout the kingdom, and published in three large volumes under the general direction of the bureau of statistics.—The first general enumeration of the kingdom of Greece was made in 1836. The census was taken annually till 1845, and subsequently in 1848, 1853, 1856, 1861, 1868, and in May, 1870. Prior to 1861 a mere enumeration of the inhabitants was made; since that date the range of inquiries has been greatly extended and more comprehensive official publications have appeared. The movement of the population is determined from civil registers kept by the municipal authorities. Tables of births, deaths, and marriages are published at irregular intervals.—In Turkey the object of the census, which is very imperfect, is to provide the basis for taxation and conscription. A census officer in each province prepares an annual exhibit of the number of births, deaths, absentees and

travellers, public health, movement of real property, taxable values, and losses by fire, disease, &c. An annual statement is prepared by the head of each village of the age, occupation, religion, military service, liability to taxation, &c., of every male inhabitant under his jurisdiction. This statement is transmitted to the comptroller of the census of the province, and by him forwarded after verification to the chief comptroller of statistics in Constantinople.—In France the first census of which the records are extant was taken in 1700, the results of which were published in 1720. During the latter half of the 18th century numerous statistical reports relating to population and other subjects were published by the government as well as by individuals. A general enumeration of the population was made in 1800, and in the following year it was decreed that a national census should be taken every five years. Pursuant to this law censuses were taken in 1806 and 1821; and in 1826 the extent of the population was computed. Since 1826 the census has been taken regularly at quinquennial periods. The last, however, was taken in May, 1872. In 1836 individual schedules were used, in which the age of each person was for the first time recorded. Up to that time only the legal population had been ascertained, but in 1841 the actual population was made the basis of the census. The enumeration has been usually made in May and June. The inquiries embrace surnames and Christian names, sex, age, civil state, birthplace, occupation, religion, degree of instruction, and infirmities of many kinds. At times other subjects of inquiry, such as the proportion of the rural to the town population, diseases, the number of households, inhabited and uninhabited houses, buildings in course of construction, and live stock, have been connected with the census. Statistics relating to population are also derived from other sources. Particulars of births, marriages, and deaths are taken from the civil registers. Reports are prepared of cases of mental aberration, of the inmates of public charitable and penal institutions, of charitable associations, life annuity and insurance companies, savings banks, and public pawn houses. The judicial authorities furnish criminal statistics annually. The reports of population are prepared by the *bureau de la statistique* in the ministry of commerce, agriculture, and public works.—The first census of Great Britain was taken in 1801, and embraced the sex but not the age of all subjects, the number of families, and the occupations, classified so as to exhibit the number employed in agriculture, in trade and manufactures or handicrafts, and those not comprised within these two classes. The first census of Ireland was taken in 1811, but not until recently have the results been received as trustworthy. Dr. Jarvis considers the Irish census of 1841, 1851, and 1861 among the best in the world. In Great Britain and Ireland the census is decennial, and includes the

general statistics of population. For climatic reasons, the month selected is March or April. The most recent census was taken in 1871. The census of Ireland was intrusted to a royal commission, that of Scotland to the registrar general of Scotland. Great Britain was divided into 32,606 districts, to each of which a special enumerator was appointed. Each enumerator had a district of less than two square miles in area, and containing an average of 131 houses and 696 persons. In addition to the 32,606 enumerators, there were 627 superintendent registrars and 2,197 registrars. The police assisted in enumerating the houseless population. The army and the navy were returned by the naval and the military authorities; the merchant seamen by the customs officers and the registrar general of merchant seamen; and British subjects in foreign states and in India, and the population of the colonies, by the secretaries of state for foreign affairs, India, and the colonies. "Householders' schedules," distributed in advance, were required to be filled up on the night of April 2, and were collected by the enumerators the following day. These schedules contained inquiries in regard to the name, relation to head of family, condition, sex, age, occupation, and birthplace of every person in Great Britain; and also as to the number of blind and deaf and dumb. Travellers were enumerated at the hotels and houses at which they arrived, on the following day. At the same time schedules were delivered in the proper quarters for collecting information respecting places of worship, schools, and miscellaneous institutions. In Ireland the census has been taken by the constabulary force. The mode of enumeration is essentially the same as in England. The schedules, however, are more comprehensive, and include inquiries relating to insanity, idiocy, degree of education, school attendance, religion, civil state, when married, birthplace, language, residence, and buildings other than habitations. An agricultural census has been taken in Scotland and Ireland for many years. A cattle census was taken in England for the first time in May, 1866, and was followed soon after by a more comprehensive agricultural census. The movement of the population of the United Kingdom is annually determined by the registrar general's office, through the agency of the district registrars. Besides the registrar general's office, there exists in almost every department of the British government a special statistical service for the preparation and publication of statistical reports upon the various interests of the kingdom.—The origin of the American census may be traced to the colonial period, when the British board of trade caused enumerations of the population to be made at different times, which was done under the immediate direction of the colonial governors, through the agency of the sheriffs and their deputies. These produced, however, little more than approximations to the actual number of the population.

The census of the United States presents the unusual fact of being ordained by the constitution of the government, the first article of which prescribes a general enumeration of the people within three years after the first meeting of congress, and within every subsequent term of ten years thereafter. The immediate object of the census was the apportionment of representatives and direct taxes. The agents employed to ascertain and report the elementary facts are the United States marshals in the several states and territories. The first census was taken in 1790, and recorded the names of heads of families, enumerated the free white males of 16 years and upward, the same under 16, and gave the number of females and the number of slaves. The second and third censuses distinguished the sexes and colors of free persons, classifying the free males under 10 years of age, those from 10 to 16, 16 to 26, 26 to 45, 45 and upward; the slaves were simply taken by number. In 1810 the marshals were directed to make return of the several manufacturing establishments and manufactures within their several districts. A like division was made of population by the fourth census, which distinguished the number of persons engaged in agriculture, commerce, and manufactures respectively. By this census an account of manufactures was returned, and a digest thereof was published in 1823. The enumeration of the fifth census distinguished the sexes of all free white persons, and the ages of white males and females, by periods of 5 years up to the age of 20, thence by periods of 10 years to the age of 100 and upward, specifying the deaf and dumb and blind under the age of 14, those between 14 and 25, and those over that age; the free colored persons and slaves were classified by sex, and the ages under 10, and from 10 to 24, 24 to 36, 36 to 55, 55 to 100, and 100 and upward, distinguishing the colored deaf and dumb and blind without regard to age. The sixth census, taken in 1840, distinguished the whites by sex and by age, as follows: 1, all under 5 years, thence to 10, thence to 15 and 20, thence by tens to 100 and upward, specifying the deaf and dumb, blind, insane, and idiotic; the free colored population and slaves by sexes and ages, first under 10, thence to 24, 36, 55, 100, and those above 100; also the deaf and dumb, blind, insane, and idiotic, without respect to age. In this enumeration the marshals were required to take a census of persons receiving pensions from the United States, with the name and age, and to make returns of mines, agriculture, commerce, manufactures, and schools. In 1850 the scope of inquiry was so greatly enlarged as to make that year an epoch in the growth of the census in this country. For the purpose of preparing adequately for the greatly enlarged work proposed to be undertaken in the enumeration, a census board was established provisionally, consisting of the secretary of state, attorney general, and postmaster general. Upon the disso-

lution of this board the control of the census, which had been previously in the department of state, was transferred to the department of the interior, under the provisions of the act of May 23, 1850, and the office of superintendent of census was created. The census of the United States has continued to be taken under the law of 1850, though this is regarded as very defective. In order to facilitate comparisons, the general forms and moulds of preceding census publications were retained in that of 1870, there being for the first time no return of slaves. But the important improvements made in existing schedules, and the addition of new tables, together with the superintendence of the eminent statistician, Gen. Francis A. Walker, give to the ninth census a completeness of detail and accuracy of result not presented by any previous one; while as a comprehensive exhibit of the social and industrial condition of a people, it surpasses the censuses of all other countries. The constitution contains no requirement for any enumeration of persons outside the several states; but the census law of 1850 makes provision for enumerating the inhabitants of the territories upon the same terms as those of the states; and even prior to the adoption of that law the territories were included in the census. There is no provision for an enumeration of tribal Indians, but the statistics concerning this class of the population in the census of 1870 were obtained by extensive inquiries conducted through the agents of the Indian office. Statistics relating to commerce and navigation and immigration are not within the province of the census, but are reported regularly by the bureau of statistics. In the United States the legal and not the actual population are enumerated. In the census of 1870 the general tables of population give the number of families and dwellings, with the average number of persons to each, the number of white, colored (distinguished as black and mulattoes), Chinese, and Indians, showing the age, sex, and nationality, and whether either or both parents were of foreign birth. The classification of ages adopted for the first time gives the number under one year, by years up to 5, from 5 to 10, 10 to 15, 15 to 18, 18 to 20, 21, 21 to 25, by quinquennial periods from 25 to 80, and by single years from 80 upward; thus exhibiting the number of the school, the military, and the voting age. Dr. Edward Jarvis of Dorchester, Mass., the highest American authority on vital statistics, maintains that the population should be exhibited by states in each year of age, as necessary to determine many anthropological questions, and as having an important agency in the development of political and social science. This is done in many European countries, with valuable results. Another most important feature which appears for the first time in the ninth census is the distinction between native and foreign-born in the tables of age and sex; this will indicate how foreigners,

as distinguished from natives, are affected by the climate and the other conditions of life in the United States. Next to the enumeration of inhabitants, the occupations of the people, as illustrating their industrial and social character, form the most important features of the census. In preparing for the ninth census special attention was given to this class of statistics, which show the number of persons of each sex from 10 to 15 years of age, from 15 to 60, and 60 and over, with nativity, in each occupation, arranged under the general heads of agriculture, professional and personal services, trade and transportation, and manufactures and mining. The tables of school attendance and illiteracy show the total number that attended school, distinguished as native and foreign, together with the white, colored, Chinese, and Indians of each sex; the number over 10 years of age who cannot read, and those unable to write, distinguished as native and foreign, with classifications of color and sex, distinguishing also Indians and Chinese, for three periods of life: 10 to 15, 15 to 21, and 21 and over. Previous tables of illiteracy gave only the number over 21 years of age who could not read and write. The blind, the deaf and dumb, the insane, the idiotic, and those appearing in two, three, or four classes of these unfortunates, are classified by race, place of birth, age, and sex. It was also sought in the census to show, for each month in the year, the number of births, of marriages, and of deaths, thus making the vital statistics of the United States comparable in these particulars with those of many European countries which give the month for the three capital events of life. The returns of marriages, however, were found to be so far imperfect as not to justify publication. In the opinion of Superintendent Walker, the experience of this census, as well as of the censuses of 1850 and 1860, "has shown that the statistics of this subject are only to be collected through a permanent registration, and under a system of penalties." The same authority claims that statistics showing the month of birth for all children born within the census year are of a high degree of value for nine months, as they exhibit with accuracy the varying influence of the seasons upon human reproduction in each section of the country; but in the 10th month, counting backward from the date of enumeration, a very perceptible disturbance is introduced, while in the 11th and 12th months the number of births diminishes with extraordinary rapidity almost to zero. Thus the number of births reported in Massachusetts in May, 1870, was 3,771; in April, 3,430; in March, 3,287; in February, 3,139; in January, 3,117; in December (1869), 3,229; in November, 2,705; in October, 2,899; in September, 2,830; in August, 2,429; in July, 1,584; in June, 567. This significant peculiarity is attributed by Superintendent Walker to the tendency of families to speak of infants of between 11 and 12 months of age, and even between 10 and 11 months, as a year old. Dr.

Jarvis, however, after a most thorough and intelligent examination of the subject, reaches the conclusion that little children were incompletely reported by the ninth census. The mortality statistics are presented by states, and exhibit the various causes of death, and the specified occupations of those having died, with distinction of race, color, sex, and age. The classification of age exhibits the number having died under one year of age, by years up to 5, by quinquennial periods from 5 to 95, and those of 95 and over. The causes of death are distributed into the general classes of unknown, general diseases, local diseases, conditions not necessarily associated with general or local diseases, poisons, parasites, malformations, and accidents and injuries. The proportion of deaths by selected diseases to the total number of deaths, and also to the number of persons living, is given for each state and territory. The scientific direction of the compilation of the tables of mortality was assumed by the surgeon general of the army, and the compilation, in respect to the classification of diseases, and to the periods of time and the sections of territory to be separately presented, was conducted under the supervision of Assistant Surgeon J. J. Woodward, U. S. A. The schools are classified as public, classical, professional, technical, and all other, with the kinds and numbers in each class, together with the teachers and pupils of each sex in each kind, and the school income, distributed into three sources. The statistics of libraries show the total number of all classes, with the number of volumes in each, distinguishing the private from those other than private, the latter being classified as United States, state, and territorial, town, city, &c., court and law, school, college, &c., Sunday school, church, historical, literary, and scientific societies, charitable and penal institutions, benevolent and secret associations, and circulating libraries. Newspapers and periodicals are classified by the various periods of issue, with the number, circulation, and copies annually issued in each class, distinguishing those devoted to advertising, agriculture and horticulture, benevolent and secret societies, commercial and financial, illustrated, literary, and miscellaneous, devoted to nationality, political and religious, sporting, technical, and professional. The number of church organizations, edifices, and sittings, and value of property are given for each denomination. In the tables of wealth, taxation, and public debt are exhibited the assessed and true value of real and personal estate; taxation, classified as state, county, town, city, &c.; and public debt, with the same classification, and the bonded distinguished from all others. Many new and valuable features have been introduced into the agricultural schedules, the most important of which is that showing the total value of farm productions, which removes the difficulty that statisticians have experienced in approximating to a correct total

valuation of the agricultural production of the country. The general statistics of agriculture present by states, territories, and counties the number, size, and value of farms, with the value of farming implements; the acres of improved and unimproved land; the amount of wages paid during the year; the value of orchard, garden, and forest products respectively, of home manufactures, and of animals slaughtered or sold for slaughter; the total value of all live stock, with an enumeration of the kinds; the crops produced, spring and winter wheat being distinguished, dairy products, wax and honey, and sugar and molasses, classified as cane, sorghum, and maple. Selected statistics of agriculture are given for townships where the value of all productions equals or exceeds \$100,000. The statistics illustrating the various manufacturing resources of the country are of exceptional value and interest. The steam and water power of the country employed in manufactures is reported for the first time, as no statistics of this kind had ever been prepared in the United States, except a report for Rhode Island and one for the city of Philadelphia. So also are presented for the first time the number of male and female adults employed, as distinguished from the children and youth, who are likewise enumerated. The general statistics of manufactures indicate the total number of establishments devoted to each industry; the number and horse power of steam engines and water wheels; the number of hands employed, classified as males above 16, females above 15, and youth; the amount of capital invested, and the annual wages paid, together with the value of materials and products. Special statistics exhibit, with a degree of minuteness not before attained, extended information concerning selected industries. Thus, in the tables of cotton manufactures, in addition to the general results mentioned above, and the number and kinds of machines employed, six columns are devoted to the classification of materials, and 20 to products; while in the report of 1860 the classification of materials was limited to two columns, and that of products to four. The statistics of mining show the extent and condition of the leading industries in the United States, and in each state and county; and similar statistics relating to fisheries are presented. Most of the above mentioned statistics are presented for states, territories, and counties, but not for civil divisions less than counties, with the exception of the population tables. But the census report includes tables for 50 principal cities having a population of more than 25,000, showing the area, families and dwellings, with the average number of persons to each, also the number of persons in each class of occupations, with age and sex, and selected nativities. It also contains historical notes respecting the area and political organization of the United States, and its geographical divisions, with descriptions of parcels of territory into which the territory of

the United States has been divided by the successive boundaries of political divisions, and tables showing the parcels of territory composing each political division at specified dates. One of the most important features of the census report of 1870 is the geographical illustration of important subjects by means of maps, which is now introduced for the first time. These maps represent the whole area of the United States; most of them are double, presenting two distinct subjects, generally selected for purposes of direct contrast. The population volume is illustrated with seven maps, which exhibit the density of total population; the distribution severally of the colored and the foreign elements of population; the dispersion over the states of the natives of certain specified foreign countries, viz.: Germany, Ireland, Sweden and Norway, England and Wales, China, and British America; the illiteracy and the wealth of each section in contrast; and the geographical and political divisions of the United States at each period of its existence, from the organization of the government to the latest census year. The volume on vital statistics contains seven maps showing the range, and, within the range, the degree of prevalence of four specific diseases, or groups of diseases, viz.: consumption, typhoid, typhus, and enteric fevers, malarial diseases and dysentery, diarrhœa, and enteritis; also the annual distribution of rain and the courses of the lines of equal temperature, thus affording instruction upon the agricultural capabilities of the country and the conditions of human life in the United States; and a physical chart presenting the most complete and accurate series of elevations yet attained. The five maps illustrative of the volume on industry exhibit the extent of cultivation of five principal crops, cotton, corn, wheat, hay, and tobacco, and also the dairy products of each state and section; also eight principal geological formations of the United States. The results of the ninth census appear in three quarto volumes: I. Population and Social Statistics; II. Vital Statistics; III. Industry and Wealth. A compendium has also been prepared for wide popular distribution, and congress has authorized the preparation and publication of a statistical atlas of the United States, based on the results of the ninth census, to consist of not more than 50 maps, to be compiled by Francis A. Walker, late superintendent. The period contemplated by law for the completion of the enumeration in 1870 was about 100 days; but the enumeration, which was begun June 1, 1870, was not substantially completed till Jan. 9, 1871, and the last returns were not received in Washington till Aug. 23, 1871. The enumeration was made by the 61 United States marshals and 6,572 assistants. The compilation and preparation for the press were performed in Washington under the personal supervision of Superintendent Walker. This work was completed by Nov. 1, 1872; soon after which the first volume was given to the

public, and the remaining two volumes early in 1873. This early publication of the complete results of the census is unprecedented. The total cost of the census, exclusive of printing the results, was about \$3,500,000.—Independent of the federal census, most of the states, either in their constitutions or by act of legislature, have made provision for enumerations of their respective populations. The following statement exhibits the date of the first census in each state, with the interval at which succeeding censuses are to be taken:

STATES.	Date of first State Census.	Subsequent Interval, Years.
Alabama	1875	10
Arkansas	1875	10
California	1852, 1855	10
Florida	1875	10
Indiana	1865	6
Iowa	1850*	10
Kansas	1865	10
Kentucky	1850, 1858	8
Louisiana	1875	10
Massachusetts	1857, 1865	10
Michigan	1854	10
Minnesota	1865	10
Mississippi	1875	10
Missouri	1875	10
Nebraska	1875	10
Nevada	1867, 1875	10
New Jersey	1855, 1865	10
New York	1855	10
North Carolina	1865	10
Oregon	1865	10
Pennsylvania	1864	7
Rhode Island	1865	10
South Carolina	1869, 1875	10
Tennessee	1871	10
Wisconsin	1855	10

In the states not named in the above table, no provision is made for a separate census.—The first census of Brazil was taken in 1872. There was a census taken in the Argentine Republic in 1869, in Colombia in 1870, and in Egypt in 1862. In Abyssinia, Persia, and other eastern nations, there is either no census, or merely a general estimate of the population. In China there has been no census since that of 1812. The extent of the population is ascertained by estimates. The census of 1711 is the first on record that bears the appearance of credibility.—The subject of census systems has in recent years caused much discussion among statisticians and publicists of all countries, with the view of adopting such methods as will make the census of each nation the most comprehensive and accurate exhibit of the social and industrial condition of its people. The importance of such information in promoting the usefulness and happiness of a nation has been fully recognized. International statistical congresses for the consideration of these and kindred questions were held at Brussels in 1853, at Paris in 1855, at Vienna in 1857, at London in 1860, at Berlin in 1863, at Florence in 1867, at the Hague, Netherlands, in 1869, and at St. Petersburg in 1872. In these congresses it was strongly recommended that the

* Required in 1859, 1863, 1865, 1867, 1869, 1875, and every 10 years afterward.

census should be taken by means of prior schedules at least decennially on a single day, at the end of the year, when the smallest number of people are away from home, and should be by names and based upon the principle of the actual population, with data for determining the legal population. Statisticians have agreed that the following inquiries relating to persons are indispensable: name, sex, age with date and year of birth, relation to head of family, civil or conjugal condition, profession or occupation, birthplace, and whether blind or deaf and dumb; and that the inquiries, where practicable and expedient, should also extend to language spoken, religion, residence, whether usual or temporary, children receiving instruction at school or at home, persons of unsound mind in public or private asylums, hospitals, and establishments. "The great object of the census," says Dr. Jarvis, whose study of the census systems of all countries has

placed him in the front rank of authorities on this subject, "is to develop those points that best show the human status, the measure of vitality, the personal, domestic, and social conditions. It is important to make this analysis of nations as minute as possible, to learn as nearly as may be the exact measure of all the elements of force in each individual, and know what and how much he has in himself, and can contribute to the sum total of national power and wealth." In a recent examination of the census of 24 nations and 8 states and provinces, Dr. Jarvis found that no two were alike in their full purposes; only England and Scotland include the same inquiries in their schedules. The following table, prepared by him, exhibits the personal inquiries made by the principal countries of Europe and by the United States at their enumerations, and published in their census reports; several countries not named are counted in the final column:

SUBJECTS OF INQUIRY.	Hanover.	Norway.	Sweden.	Russia.	Danmark.	Prussia.	Austria.	Holland.	Belgium.	France.	Switzerland.	Italy.	Spain.	Portugal.	England.	Ireland.	United States.	Massachusetts.	New York.	Canada.	States making this inquiry.

Of 34 personal inquiries, it will be seen, only one, sex, is made by all. Age is inquired by all except Russia; name is omitted by Russia, Hanover, Baden, and Switzerland; birthplace by Norway, Russia, Prussia, Hanover, and Austria; civil condition by Russia, Baden, and the United States; and occupation by Norway, Russia, and Baden. Families, houses, religion, and the number of the blind and deaf and dumb were noted by nearly all. The United States is the most inquisitive; Ireland, France,

and Italy come next in the order of the minuteness of investigation. In many European countries the enumeration is made in one day. In the United States the system of a protracted enumeration has been adhered to, which in the opinion of eminent statisticians will necessarily give but an approximation to the real number of inhabitants. The liability to error from this cause is comparatively small in rural districts; but in cities and manufacturing towns, where the inhabitants change their

residences more frequently, the percentage of loss becomes very considerable. Superintendent Walker maintains that "if the formation of subdivisions and the confirmation of assistants were vested in the department of the interior, with proper discretion as to the use of special agents, it would be possible to take the census of every city and manufacturing town in the United States in a single day, and to complete the enumeration of all properly agricultural sections in a period not exceeding three days, allowing, if need be, for the completion of the purely mining states and the territories, and perhaps for some portions of Texas, California, Kansas, and Nebraska, a longer period of time, not to exceed 30 days. Such an enumeration could be accomplished in the present condition of the settlement of the United States. It would cost little if any more than a census taken according to the present methods, and would be inexpressibly more satisfactory." The use of "prior schedules" in taking the census has been unanimously recommended by statisticians, not only as effecting a saving of time and expense, but also a higher degree of accuracy in the enumeration. These schedules, containing printed inquiries and directions as to filling up, are distributed among families, and, after having been by them filled up, are collected by the census agents. This plan has been adopted with great advantage by most of the European countries, but has not been introduced into the United States, though its adoption has been urged upon the government by Dr. Jarvis and other high authorities. In the United States, Great Britain and Ireland, Holland, Belgium, Switzerland, Portugal, and Sweden and Norway, the census is decennial; while in Denmark, France, and Austria it is quinquennial. Most of the German nations and principalities take their census once in three years.

CENT (Lat. *centum*, a hundred), a United States coin of the value of $\frac{1}{100}$ of a dollar. The act of April 2, 1792, authorized the coinage of a copper cent weighing 264 grains, and a half cent in proportion. The weight of the cent was reduced by the act of Jan. 14, 1793, to 208 grains, and by the act of Jan. 26, 1796, to 168 grains, the half cent being proportionally reduced. The first coinage was executed in 1793. A three-cent coin, three fourths silver and one fourth copper, weighing $12\frac{3}{4}$ grains, was authorized by the act of March 3, 1851, to be a legal tender for any sum not exceeding 30 cents. By the act of March 3, 1853, the fineness of this coin was raised to .900, and its weight reduced to $\frac{2}{3}$ of the half dollar, or 11.52 grains. The coinage of the half cent was discontinued by the act of Feb. 21, 1857, and for the old copper cent was substituted a new coin, composed of 88 per cent. copper and 12 per cent. nickel, weighing 72 grains, which continued to be coined until the act of April 22, 1864, provided for the coinage of the bronze cent, consisting of 95 per cent. copper and 5 per cent.

tin and zinc, and weighing 48 grains. The same act authorized the coinage of two-cent pieces weighing 96 grains, and made the one-cent and two-cent coins a legal tender for sums not exceeding 10 cents and 20 cents respectively. A three-cent coin, three fourths copper and one fourth nickel, weighing 30 grains, was authorized by the act of March 3, 1865, which made this coin a legal tender for any sum not exceeding 60 cents. By the same act the one and two-cent coins became each a legal tender to the amount of 4 cents only. The act of May 16, 1866, provided for the coinage of a five-cent piece, three fourths copper and one fourth nickel, weighing 77.16 grains, which was made a legal tender for any sum not exceeding \$1. By the act of Feb. 12, 1873, known as the "coinage act of 1873," the issuing of coins of the denomination of cent, except a five-cent piece and a three-cent piece (three fourths copper and one fourth nickel) weighing 77.16 and 30 grains, and a one-cent piece (95 per cent. copper and 5 per cent. tin and zinc) weighing 48 grains, was discontinued, and the coins authorized by the act were made "a legal tender, at their nominal value, for any amount not exceeding 25 cents in any one payment." Before the adoption of the constitution, cents were coined under the authority of the confederation at New Haven, in 1787, and about the same time cents and half cents were coined by local authorities in Vermont and Massachusetts. The number of coins of each kind produced at the mint from its organization to July 30, 1872, is as follows:

Five-cent pieces...	98,474,000	Two-cent pieces...	45,691,000
Three " (nickel)...	23,701,000	One " "...	477,911,244
" (silver)...	42,007,490	Half " "...	7,955,223

The total number of pieces is 697,679,957, valued at \$12,686,013 25.—Also, a Canadian copper coin, the multiples of which, pieces of 5, 10, 20, 25, and 50 cents, are of silver, having a fineness of .925. These coins are worth about 5 per cent. less than those of the United States of corresponding denomination. (See COINS.)

CENTAURS, a mythological race of beings, half man and half horse, who were supposed to inhabit the mountains and forests of Thesaly, where they led a wild and savage life. One legend was that Ixion, having been refused all intercourse or fellowship with the human race in consequence of the murder of his father-in-law, Deioneus, was invited by Jupiter to reside on Olympus; but, forgetful of the rules of hospitality, he attempted to seduce Juno, the wife of his entertainer. A cloud woman in the semblance of Juno was substituted in her place, and Ixion boasted that he had triumphed over the queen of all the gods. In punishment thereof he was bound to an ever-revolving wheel in the abyss of Tartarus. From this union between Ixion and the phantom, according to one form of the legend, the centaurs were directly produced. According to others, the offspring of the union was a being

in human shape named Centaurus, who was hated alike by gods and men. Wandering wild over Mount Pelion, he begot the centaurs out of the Magnesian mares. Another story is

The Centaur Chiron and Cupid.

that while Pirithous, one of the Lapithæ, was celebrating his nuptials with Hippodamia, one of the centaurs carried her off. This led to the great fight between the centaurs and the Lapithæ, in which the centaurs were defeated. In early times the centaurs were represented in sculpture as men down to their legs and feet, but having a hind part consisting of the body, tail, and hind legs of a horse. But afterward they were represented as horses, perfect in all respects below and behind the withers and the chest. At the insertion of the neck a human body began, the hip joints articulating into the shoulders of the lower animal, and the abdomen of the man uniting with the chest of the horse. Above this the human conformation was perfect, with the erect bearing, chest, shoulders, arms, neck, and head of a complete man. They were represented as endowed with extraordinary powers of body and mind. Porphæus, one of the later Greek writers, undertook, in his work *Περὶ Ἀπίστων*, to explain the origin of the myth of the centaurs. According to him, they were a body of young men of a town in Thessaly who first used horses for the purpose of riding. Thus mounted, they pursued the wild bulls, and transfixed them with their spears, and hence were called *κέντρορες*, prickers, or *κενταύροι*, bull-prickers. The neighboring inhabitants, seeing men mounted on horses, imagined that the man and the animal were one being, just as the Mexicans did in the case of the Spanish cavaliers; and hence originated the fable of beings half man and half horse.

CENTAURUS, or **The Centaur**, a southern constellation, only a small part of which rises in our latitude. Two stars of the first magnitude are catalogued in the portion which does not appear above our horizon. This is one of the

48 ancient constellations formed by Ptolemy, who first discovered the likeness of a centaur in it. On the celestial maps of the Arabs it is represented by a bear mounted on horseback.

CENTAURY, a genus of plants of the family *gentianaceæ*, comprehending a large number of unimportant species, which are natives of Europe, Asia, Africa, and a very few of America. One of the species is fabled to have cured the centaur Chiron of the wound in his foot made by the arrow of Hercules, and to have hence derived its name. It was formerly supposed to have extraordinary medicinal powers, and said to cure not only fevers, but also the

Centaury.

plague, and the worst ulcers; but its properties are only those of a bitter tonic, like those of other members of the same family.

CENTIGRADE SCALE, the 100 parts, named grades or degrees, adopted particularly by the French for the thermometer. It was devised in 1742 by Celsius, professor at Upsal, the limits of the division into 100° being the boiling and freezing points of water, though the scale is made to extend to convenient lengths below and above these points. In Fahrenheit's scale, the freezing point being 32° and the boiling point 212°, 180° include the same range as 100° of the centigrade thermometer. The ratio of one degree of Fahrenheit to one of the centigrade is therefore the same with that of 5 to 9. But as the zero point of the Fahrenheit thermometer is 32° below the freezing point, which is the zero point of the centigrade, this number must be added to the results obtained from the ratio above stated. Thus, if the degree on the Fahrenheit scale which corresponds to 15° centigrade is to be found, 15 must first be multiplied by 9 and the product divided by 5; to 27, the quotient obtained, 32 must be added, and the sum, 59, will be the degree on the Fahrenheit scale required.

CENTIPEDE, an articulated animal, formerly considered an insect, but since the time of Dr. Leach placed in the class *myriapoda*, and in the genus *scolopendra*. This class is distinguished

from insects by the far greater number of feet, by the more numerous segments of the body, and by the absence of any distinct division between the thorax and abdomen. With the exception of the first, each segment has a pair of legs, terminated generally by a single hook; from the occurrence of the stigmata, or respiratory openings, on each alternate segment, Latreille and others, from the analogy of insects proper (which have two stigmata on each segment), have considered these as semi-segments, and have consequently given two pairs of legs to each segment. The feet are much approximated to each other for the whole length of the body; the mandibles are bi-articulated, and followed by a piece formed like a labium with articulated feet-like divisions, corresponding in position to the *lanquette* of crustacea; then come two pairs of little feet, of which the second, hook-shaped often, seem to replace the four jaws of crustaceans, or the two maxillæ and lower lip of insects; they may be regarded as maxillary feet. The antennæ are two, varying greatly in their shape, length, and number of joints. The organs of vision are usually formed by the union of simple eyes, but in some they resemble the compound eyes of insects, with larger facets. All myriapods are wingless. Unlike insects, in this class the number of the rings, and of the feet belonging to them, increases with their age; from the fact that some genera are born without feet, Latreille asserts that they undergo a true metamorphosis, though the separate states of larva, pupa, and imago do not exist in them any more than they do in most apterous insects. The organs of respiration consist of two principal parallel tracheæ along the body, into which the stigmata open. The myriapods seem to approximate somewhat to the crustacea on one hand, and to the insects on the other. They generally avoid the light, concealing themselves under stones, beneath the bark of trees, in old timber, and similar localities; some live in fruits, others destroy vegetables, and many feed on dead and living animal substances. Latreille divides myriapoda into two orders: 1, *chilognatha*, of which the best known genus is *iulus* (Latr.); and 2, *chilopoda*, containing the genus *scolopendra*, which, in the unrestricted latitude given it by Linnæus, included all the genera of the order, all of which have at various times been designated as centipedes or millepedes. In the order *chilopoda* the antennæ are slender toward the extremity, having 14 or more joints; the mouth consists of two mandibles with a palpiform appendage, terminated like the bowl of a spoon with indented edges; the labium is quadrid, and its two lateral divisions, the largest, are transversely ringed, and resemble the membranous feet of caterpillars; they have besides two palpi or little feet, united at the base and unguiculated at the end, and a second labium formed by a second pair of feet, terminated by a strong movable hook pierced at the end for the issue of an acrid liquid.

The body is membranous and flattened, each ring being covered by a coriaceous plate, and having for the most part but one pair of feet, the terminal segment being elongated into a kind of tail; the sexual organs are interior, and placed at the posterior extremity of the body.—The centipedes move very rapidly in an undulating manner; they can walk backward, using only the four hind legs, which in ordinary progression are dragged after them. They are carnivorous, and are much dreaded by the inhabitants of warm climates, where they attain a large size, and are capable of inflicting dangerous wounds; it is said that their bite, though more painful than that of the scorpion, is never fatal; the common species of Europe (*lithobius forficatus*, Linn.), very abundant under stones in the summer season, is quite harmless, though repulsive in its aspect. The genus *scutigera* (Lam.) has the body covered with 8 plates, 15 pairs of legs, and large reticulated eyes; they are nocturnal in their habits, and pierce their insect prey with their mouth-hooks, producing almost instant death; according to Illiger, they are dreaded by the inhabitants of Hungary. The genus *scolopendra*

Scolopendra morsitans.

(Leach) has 21 pairs of legs, of which the basal joints of the terminal legs are armed with spines; the segments are nearly of equal size and number above and below. The *S. cingulata* (Latr.) of southern Europe is almost as large as some of the species of tropical America. Several species of South America and the West Indies have doubtless been confounded under the *S. morsitans* (Linn.), one of which grows to the length of a foot; very large species also occur in Asia, Africa, and the Indian archipelago. Ammonia is the best application to their bites. Of the genus *cryptops*, Dr. Leach mentions two species found in the vicinity of London; the eyes are very small, the antennæ are grained, and the basal joint of the more slender hind feet is without spines. In the genus *geophilus* (Leach), the antennæ have only 14 joints, but the legs vary in number from 42 to nearly 300; they are very slender, and some are phosphorescent; they are destructive to fruit and vegetables.—The position of the myriapoda can hardly be said to be determined. Siebold says they do not properly belong either to *arachnida* or *insecta*, and he classes them under *crustacea*. Rymer Jones observes that they differ from crustacea

by their respiring air by means of tracheæ, and from annelids by their jointed legs, and that they seem to be an osculant group, allied to annelids, insects, arachnida, and crustacea; they have urinary organs like insects, which crustacea have not. Prof. Agassiz makes them the lowest order of the class of insects, the other orders being arachnids and insects proper. Newport traces the nervous system from the highest *chilognatha*, the most perfect of which are connected on the one hand with crustacea and on the other with true insects, through the *geophili* (the lowest vermiform type of the *chilopoda*), to the tailed arachnida (the scorpion), and through *scelopendra*, *lithobius*, and *scutigera*, the last of which connects the myriapoda on the one hand with true insects, and on the other with arachnida. The heart or dorsal vessel, as in insects and arachnida, is divided into several compartments, corresponding in number to the abdominal segments.

CENTLIVRE, Susanna, an English dramatic writer, born in 1667, died in London, Dec. 1, 1723. She was daughter of a Lincolnshire gentleman named Freeman. Left an orphan at the age of 13, and ill-used by those who had charge of her, she fled to London. At the age of 16 she was married to a nephew of Sir Stephen Fox. A year afterward she was a widow; but her wit and beauty soon brought her another husband, an officer in the army, named Carrol. A year and a half after this second marriage her husband was killed in a duel, and she was obliged to depend upon her pen for support. Under the name of Carrol she published some poetry and a tragedy, "The Perjured Husband." She attempted but one more serious drama, but wrote several successful comedies, some of them before she was 19 years old. She also performed on the stage for a brief period, and in 1706, while she was playing in Lee's "Rival Queens" before the court at Windsor, she won the heart of Joseph Centlivre, principal cook to Queen Anne, and married him. She was intimate with Steele, Sewell, Rowe, Farquhar, and other men of note, and incurred the enmity of Pope, who exhibited his malice toward her in the earlier editions of the "Dunciad." She wrote 19 plays, all of them noted for the ingenuity of the plots and the vivacity of the dialogue; but only three of them have kept the stage, "The Busy-Body," "A Bold Stroke for a Husband," and "The Wonder, a Woman Keeps a Secret." Her works, with a biography, were published in 1761 (3 vols. 12mo, London), and a facsimile edition was published in 1872.

CENTO (Latin, patchwork), a poem composed wholly of verses taken from one or more poets, but disposed in a new order so as to form a distinct work. The only classical example is the *Cento Nuptialis* of Ausonius, formed out of Virgilian verses perverted into a new meaning. The empress Eudoxia wrote the life of Jesus Christ in Homeric centos;

Proba Falconia, under the emperor Honorius, wrote the same in verses extracted from Virgil. The same subject was treated in a Virgilian cento by Alexander Ross, a Scotch schoolmaster and poet, in his *Virgilius Evangelizans*, which was republished in 1769. The term cento is also applied to a medley, or a work composed of selections connected by appropriate passages.

CENTRAL AMERICA, the narrow, tortuous strip of territory connecting North and South America, extending from about lat. 7° to 18° N., in length from 800 to 900 m., and varying in breadth from about 30 to about 300 m. It comprises five independent republics, Costa Rica, Guatemala, Honduras, Nicaragua, and San Salvador, with a united area of 175,000 sq. m., and a total population of 2,665,000. Throughout its entire length the country is traversed by a chain of mountains consisting of three groups: the Costa Rica, which traverses the republic of that name and the isthmus of Panama, the Honduras and Nicaragua, and the Guatemala, with peaks from 3,000 to 11,000 ft. in height. The volcanoes Fuego and Agua are 13,000 or 14,000 ft. high. The inequality of the surface produces great variety in the climate and vegetable productions, the country producing the fruits and grains of Europe and America, and sugar cane, indigo, cochineal, tobacco, cotton, and all the fruits of the tropics. The zoology is similar to that of other American countries; but Central America is remarkable for the variety and beauty of its humming birds, macaws, and the quezal, which has a brilliant plumage of emerald green. Large and dangerous serpents are numerous, and the country is infested with two species of locusts, one of which is particularly destructive. The rivers and bayous abound in fish. The geology exhibits granite, gneiss, and mica slate as substrata, with an abundance of igneous rocks showing volcanic action. There are gold, silver, iron, lead, and mercury deposits, and the gold, silver, and iron mines are worked to some extent. Much salt is obtained both from springs and from the sea on the Pacific side. The people are divided into three classes, whites and creoles, mestizos, or the offspring of whites and Indians, and the aboriginal natives. The commerce is insignificant. The interest of the country centres mainly in its two or three practicable routes for interoceanic canals between the Atlantic and Pacific.— In 1502 Columbus visited the east coast; in 1523 Cortes sent Pedro Alvarado to subdue the country, and in 1525 he completed the conquest. It remained subject to Spain till 1823, when the five colonies formed themselves into a federal republic of independent states; this arrangement continued till 1839, when the federation was dissolved. Subsequent unions were effected and dissolved; and representatives of the five states met at La Union, San Salvador, Feb. 17, 1822, to consider the formation of a new confederation, but without result.

CENTRAL CITY, a town and the capital of Gilpin co., Colorado, situated partly in the valley of a tributary of North Clear creek and partly on the slopes of the surrounding mountains, 39 m. W. of Denver; pop. in 1870, 2,360. It is irregularly but substantially built. Its site is 8,300 ft. above the level of the sea. The streets are narrow, and some of them steep and rugged. Being in the centre of an exceedingly rich gold-mining region, it is at once a depot of supply and a point of shipment. The bullion shipped in 1870 amounted to \$1,650,000. The town has a United States land office and an assay office. There are two hotels, a miners' and mechanics' institute with a library of about 1,000 volumes, and Catholic, Methodist, and Episcopal churches, with the last of which is connected a parish school. The high school building is of stone, and cost \$20,000. St. James library association has about 500 volumes. A daily and two weekly newspapers are published. There are a number of quartz mills, and a national bank with a capital of \$50,000.

CENTRAL HEAT. Since the year 1740, when the first observations respecting the increase of heat encountered with the increased depth below the surface were made by M. Gensanne in the lead mines of Giromagny in S. Alsace, abundant data have been collected by scientific men in various parts of the world in support of the theory that the interior of the earth is intensely hot. The deepest mines of Mexico, England, France, Germany, and other countries, and the deeper artesian wells, and the hot springs ascending from still deeper sources, all lead to this conclusion. The volcanic fires add their testimony to the existence of intensely heated masses beneath the crust of the earth, and the vast extent of surface agitated when they are suppressed, and relieved by their outlet, seems to indicate an almost general diffusion of the liquid molten masses from which they spring. Not only is the heat found generally to increase with the depth, but the rate of this increase has in many instances been determined. It is found to vary in different countries, in some increasing two or three times more rapidly than in others. The average rate is estimated by Kupffer at 1° F. for every 37 English feet; and by Cordier at 1° for every 45 feet. These phenomena, all pointing in one direction, have led to the conclusion that somewhere in the interior the materials of the globe must be in a state of the most intense heat; and calculations have been made showing at what depth the rocks must all exist as liquid lava, at what the temperature of melted iron would be found, at what platinum would fuse, and at what various matters, solid at the surface, would be volatilized, but for the enormous pressure. This theory is controverted by Sir Charles Lyell, M. Poisson, and other eminent authorities, on these grounds: When substances, as metals, are melted, their temperature cannot be raised a single degree above the

point of fusion so long as a piece of the material remains unmelted. The same principle is exemplified in the impossibility of raising water to a higher temperature than 32° F. so long as a fragment of ice remains in it. The principle may be applied to the solid crust of the earth, which could no more remain unchanged, reposing upon the surface of a fluid heated many times above the temperature at which its materials would melt, than a stratum of ice of the same thickness could remain in the same situation exposed to the same proportional difference of heat. The crust that forms upon lava as it cools cannot be instanced in disproof of this statement, for this only forms when the heat is so much reduced that ebullition has entirely ceased; if this be renewed, the crust soon disappears in the fluid. Were the crust of the globe the result of partial cooling from a state of primitive fluidity, the whole planet must first have cooled down to about the temperature of incipient fusion, and hence the enormous degrees of heat supposed cannot exist within it. M. Poisson "imagines that if the globe ever passed from a liquid to a solid state by radiation of heat, the central nucleus must have begun to cool and consolidate first."

Were the central portion fluid, tides would be perceived in the mass, sufficient to cause the surface to rise and fall every six hours; but no such fluctuations are observed, even in a crater like that of Stromboli, which is supposed to connect with the great central ocean of lava. The phenomena that have given rise to the hypothesis of central heat do not absolutely require this theory to account for them. Local heat is without question generated by chemical changes taking place among the materials beneath the surface. These give rise to electrical currents, of the power of which to disturb the surface we can form little idea; but judging from their effects upon the limited scale on which they come under our observation, it would seem quite as philosophical to refer to them the phenomena connecting distant volcanic outbreaks and earthquakes, as to call in an aid so hypothetical as that of the molten fluidity of the central portion of the globe.

CENTRAL PROVINCES, one of the eight large administrative departments into which British India was in 1872 divided, situated between lat. 18° and 24° N., and lon. 77° and 83° E. They were formed into a chief commissionership by royal decree of Nov. 2, 1861. At first they consisted of the province of Nagpore and its dependencies, and the districts of Sangor and Nerbudda; were enlarged in 1862 by the annexation of Sumbulpore and its dependencies; and in 1872 contained an area of 112,561 sq. m., of which 84,162 were immediate British possessions, while the remainder belonged to 15 native states. According to an official report presented to parliament in 1870 ("Statement exhibiting the Moral and Material Progress of India during the years 1868 and 1869," London, 1871), the population of the British

possessions was 9,068,103, and that of the native states about 1,100,000. In 1866 there were in the provinces, according to an official enumeration, 6,064,770 Hindoos, 1,995,663 Gonds and aboriginal tribes, 237,962 Mussulmans, and 6,026 Europeans. Of the inhabitants 57 per cent. were engaged in agriculture. The British portion is divided into four commissionerships (Nagpore, Jubbulpore, Nerbudda, and Chutteesgurh) and 19 districts. The line of railroad which connects Calcutta and Bombay passes through these provinces, and has greatly contributed to their rapid progress. Numerous roads have of late been made, the number of schools has more than doubled since the organization of the chief commissionership, and the capital, Jubbulpore, has now a larger traffic passing through it than any other city of India except Bombay. The chief product is cotton, of which 653,517 lbs. were exported in 1868. The revenue of the Central Provinces amounted in 1870-'71 to £1,130,000, and the expenditures to £865,228. The largest cities are Nagpore, Jubbulpore, and Saugor.

CENTRE, a central county of Pennsylvania; area, about 1,000 sq. m.; pop. in 1870, 34,418. It is traversed by the Alleghany, Bald Eagle, and several other mountain ranges. It is drained by a number of small creeks, which supply several mills and factories with water power. The soil is excellent in the valleys, and agriculture is in a forward state. The mountains are covered with valuable timber, but furnish little land suitable for cultivation. There are extensive mines of iron, quarries of limestone, and beds of stone coal in several places. The Clearfield division of the Pennsylvania Central railroad intersects the S. W. corner, and the Bald Eagle division traverses the county. The chief productions in 1870 were 479,145 bushels of wheat, 63,108 of rye, 1,044,760 of Indian corn, 389,628 of oats, 37,256 of barley, 117,403 of potatoes, 27,725 tons of hay, 521,090 lbs. of butter, and 53,448 of wool. There were 6,588 horses, 6,484 milch cows, 9,489 other cattle, 18,017 sheep, and 15,573 swine. There were 22 flour mills, 23 manufactories of iron, 1 of window glass, 15 tanneries, 4 planing mills, 25 saw mills, 5 manufactories of agricultural implements, 28 of carriages and wagons, 2 of edge tools, 1 of machinery, 1 of wire, and 4 of woollen goods. Capital, Bellefonte.

CEOS. See ZEA.

CEPHALONIA, or *Cephalonia*, called by Homer Same or Samos, the largest of the Ionian islands, separated from Ithaca on the E. by a narrow channel. It is now one of the 13 nomarchies of the kingdom of Greece; area, about 300 sq. m.; pop. in 1871, 77,382. The country is rugged and mountainous, particularly in the N. part, and the Black mountain (anc. Mount Enos) constitutes the most picturesque feature of Cephalonia. The climate is usually mild. The soil produces little corn, but some wine, oil, honey, and all the

fruits of southern Europe. Currants, the staple product of the Ionian islands, come chiefly from Cephalonia. In 1870, the exports of Cephalonia currants were 17,746,400 lbs., valued at \$498,318, besides 2,690,240 lbs. of Morea currants. The total exports were \$857,928; imports, \$1,447,219. The harbor of Argostoli is excellent, and ship building and various other branches of trade and industry are carried on actively. The imports consist mainly of breadstuffs and of the manufactures and wares of Europe. The Greek church is the predominant religion, the remainder belonging to the Roman Catholic church. Property is much more divided in Cephalonia than in other parts of the Ionian islands. About one sixth of the cultivated land belongs to the convents, of which there are more than 20, and many of them, as for instance the convent of Sisi, are very ancient.—The island is supposed to have been originally inhabited by Taphians, and to have derived its name from the mythical Cephalus. There were four cities in Cephalonia in the times of antiquity, viz., Pale, Cranii, Proni, and Same. The site of Proni, and still more that of Same, still exhibit extensive and interesting ruins. The latter city, which was more populous than the other three, is frequently mentioned by Homer, while the inhabitants are spoken of by the poet as the Cephallenians. Thucydides called the island a tetrapolis (composed of four states), and still other names were applied to it. But the name of Cephallenia first occurs in Herodotus. The island belonged successively to the Greeks, the Macedonians, the Romans, the Byzantine emperors, the Normans, the Venetians, the Turks, and the French. From 1815 to 1863 it was with the rest of the seven Ionian islands under the protection of Great Britain. In August, 1849, an insurrection broke out in the island, which could only be suppressed by the most energetic measures on the part of the British governor. Cephalonia is represented in the parliament of Greece by ten deputies. Capital, Argostoli.

CEPHALOPODA (Gr. *κεφαλή*, head, and *πούς*, foot), the highest of the branch of mollusks. Some have no external shell, like the squid (*loligo*); others an internal one, like the cuttle fish (*sepia*); others a simple shell, like the argonaut; and others chambered shells, like the fossil ammonites and living nautilus, many being in this respect unsurpassed for symmetry and beauty among mollusks. Their most striking feature is that the head is distinct from the body, with large eyes on the sides; the posterior part of the body ends in a sac. The principal locomotive organs, whence their name, are attached to the head in the form of muscular arms or tentacles, usually eight or ten; besides these, many have fins, and all are more or less able to propel themselves backward by the forcible expulsion of water from the branchial sac through the siphon which opens on the lower surface. They are perfectly symmetrical animals, having the right and left sides

equally developed, and the shell, when present, usually straight or coiled in a vertical plane, very different from that of the spirally coiled gasteropods. The cephalopods, except the argonaut, do not occupy the whole of their shells, as do the gasteropods, but have a shell of chambers, numerous according to age, the animal dwelling in the anterior one and forming another one, with a dividing partition, as it grows larger. They are carnivorous, with powerful parrot-like jaws, moving vertically; the tongue is in part armed with recurved spines for retaining the food; all their senses

Argonaut without the Shell.

are acute; they are all marine. The nervous system is more concentrated than in other mollusks, and the anterior ganglia, or brain, are protected by a cranial cartilage, which has been regarded as a commencing cranial cavity. They breathe by two or four plume-like gills, symmetrical on each side, in a cavity beneath the body, opening externally; at the base of the gills are dilatations of the blood vessels, which send the blood to the heart after purification. The sexes are distinct, but the females are the most numerous, the malés of many being un-

Argonaut within the Shell.

known, and some, the so-called *hectocotylis*, resemble a detached arm of the animal, modified for sexual purposes. All the living cephalopods, except the nautilus, belong to the dibranchiate or two-gilled order; these are naked, free swimming animals, with distinct head, prominent eyes, eight or ten arms with numerous suckers, the body round or elongated, usually with two fins; all have an ink gland, and the walls of the funnel entire; with the exception of the argonaut, the shell, when present, is internal. These are the typical cephalopods, and higher than the tetrabranchiate or

four-gilled, creeping, many-armed shell-bearing nautilus and ammonites. Having ordinarily no external shell for defence, they have powerful arms provided with suckers, a gland for secreting an inky fluid to discolor the water, and acute senses and rapid movements. The *acetabula* or suckers are in single or double rows on the inner surface of the arms; the muscles of each cup converge to a central cavity, with a soft piston-like caruncle in the centre, by which a very strong adhesion is effected; these are perfectly under the control of the animal, which can instantly release its thousand suckers, and dart away under cover of its inky secretion, at the approach of danger; in some the base of the piston forms a toothed horny loop, or even a sharp hook. The ink bag is tough and fibrous, discharging its contents near the base of the funnel; the ink was formerly used as a pigment, and it is so indestructible as to be found fossil, and to permit the naturalist to draw with its own secretion an animal which perished millions of years ago. The skin is of various colors, and remarkable for the sudden changes which dart over it in brilliant flashes as the creature dies; they have hence been called "chameleons of the sea;" they have water pores on the head and arms. They are nocturnal or crepuscular animals, hiding by day, found in every zone and at all depths of water, as well as in the open sea; they may attain, in tropical seas, a length of six or eight feet, including the arms, and a weight of 300 lbs. The dibranchiate cephalopods have been divided into the octopods, with eight arms, like the octopus and the argonaut, and the decapods, with ten arms and more elongated body, like the squids, cuttlefishes, and fossil belemnites. The tetrabranchiate cephalopods are protected by shells, attached to the body, in the anterior chamber of which the creature dwells. They are now nearly extinct, the nautilus being the only living representative. More than 1,400 fossil species are known by their shells, which vary from perfectly straight in *orthoceras* and *baculites* to the tightly coiled ammonite and nautilus; they performed in the palæozoic and mesozoic seas what the carnivorous gasteropods did in the cenozoic and do in the present epoch. The chambers do not act to enable them to rise or sink at will; they are rarely found at the surface of the water, except in storms, but belong at the bottom, where they creep like a snail; the discoidal forms were not well calculated for swimming by their respiratory jets, and the straight ones, from the buoyancy of their shells, must have remained head downward. The use of the chambers is generally believed to be to render the animal of nearly the specific gravity of water, and thus facilitate locomotion, and that of the partitions to strengthen them against collisions, being most numerous in the delicate ammonites; the animal is probably always growing forward, except during the formation of the partitions,

which indicate periods of rest. All the cephalopods below the middle of the mesozoic strata belong to the group with chambered shells; those with internal shells do not date back much beyond the oölite age, like the belemnites; the group with chambered shells may, therefore, be regarded as the lower type. Those which have eight arms have never any shell or hard part; those which have ten have always hard parts, varying from cartilage to the horny pen of the squids, and the calcareous plates of the cuttle fishes.

CEPHALUS, in Greek mythology, son of Deion and Diomede, and husband of Procris, whom he tenderly loved. Aurora was enamored of him, and prompted him to tempt the fidelity of his wife. Disguised he came with presents to his house, and Procris fell. She subsequently seduced him, and the discovery of their mutual weakness led to a reconciliation between them. Cephalus afterward slew his wife with his spear, mistaking her for a wild animal, as she was jealously watching him in the wood. According to Ovid, Cephalus finally gave his name to Cephalonia.

CEPHISSUS, the name of two rivers in Greece, one rising in the western part of Phocis, flowing S. E., and emptying into Lake Topolias (Copais); the other the principal river of the Athenian plain, having its main source at Trinemii, between Mts. Pentelicus and Parnes, and running S. on the W. side of Athens. Formerly its outlet was in the bay of Phalerum; but so much of the water as is not exhausted in irrigation now empties through the long walls, or tunnels, at Port Piræus. In ancient Greece two other rivers were called Cephissus.

CERACCHI, Giuseppe, an Italian sculptor, born in Corsica about 1760, executed in Paris, Jan. 30, 1801. He took an active part in the establishment of the ephemeral republic of Corsica in 1798, and in 1799 sought refuge in Paris, where he joined a band of republican artists, who cherished a violent hatred against Napoleon, and at length made an attempt upon his life. The murder was to be committed Oct. 10, 1800, at the opera; but the conspirators were betrayed by one of their number, their weapons seized, and Ceracchi with his associates Diana, Aréna, Topino-Lebrun, and Demerville arrested, tried, condemned, and all but Diana executed.

CERAM, Ceiram, Strang, or Zerem, one of the Molucca islands, in the Malay archipelago, lying N. of Amboyna, between Booroo on the west and Papua on the east; lat. $2^{\circ} 47'$ to $3^{\circ} 50'$ S.; lon. $127^{\circ} 51'$ to $130^{\circ} 56'$ E.; area estimated at 6,500 sq. m.; pop. at 67,000. Its topography is imperfectly known, but the general character of the surface is hilly, several mountain ranges, from 5,000 to 6,000 ft. high, traversing the island, and giving rise to a number of streams which empty principally off the S. coast. The loftiest peak is that of Noosaheli, 7,000 ft. above the sea. The climate is salubrious, vegetation is luxuriant, and the nutmeg

and clove were produced spontaneously until extirpated by the Dutch about 1657. The sago palm here reaches the height of 100 ft., and a single tree sometimes yields 1,200 lbs. of starch. Many varieties of forest trees are found, furnishing fine woods for cabinet work, known in commerce as Amboyna wood, but none suitable for ship building. The coasts are peopled by a hardy, enterprising Malay race, who subsist chiefly by fishing, and find a market for the produce of their toil at Singapore and the Sunda islands; they also have an extensive trade with China in tripang. Their vessels, called *praus* or *kora-kora*, are manned by from 30 to 60 rowers each. Most of these people are Mohammedans, but Christian missionaries have made many converts among them. The Alfuros are the dominant tribe of the interior. They are described as an honest and in most respects peaceable race of idolaters, among whom Christianity has made some progress. A little maize, for domestic consumption or exchange for dress, firearms, and fermented liquors, is cultivated, chiefly by women; while the men are engaged in hunting. The Alfuros have prominent features, large eyes, and long frizzled hair; they are brave, faithful, obedient, and make good soldiers. In the mountains in the central part there is now but one populous village; in the east and extreme west there are a few others; but with these exceptions the inhabitants are generally on the coast. On the S. W. coast the Dutch have improved the condition of the natives by establishing schools in every village, introducing vaccination, and encouraging settlement by Europeans. New cacao and coffee plantations, affording work at fair wages, have elevated the condition of the natives. The Dutch have the sovereignty of the island, and have established several forts on it. On the N. E. coast are the bay and village of Waroo, where good anchorage, water, and provisions may be had. Off the coast of Ceram lies a small group of islands called Ceram Laut.

CERAUNIAN MOUNTAINS (Gr. τὰ Κεραυνία ὄρη, the thunder-riven mountains), a name given by the ancient Greeks to two different ranges. **I.** One belonging to the eastern extremity of the great range of Caucasus, the precise position of which is not certainly known. Strabo makes it the name of that portion of the Caucasus which overhangs the Caspian sea, and in which he places the land of the Amazons. Mela seems to apply the name to the whole chain of the Caucasus, and Pliny gives a similarly extensive signification to it. The name in fact appears to have been used at first in conjunction with Caucasus for the highest summit of the range, and afterward applied confusedly to the eastern portion of the mountains, which were very imperfectly known to the ancients. **II.** Lofty and rugged mountains in the N. part of Epirus, said to have derived their name from the thunder storms which were very frequent among them. They are often called Acroce-

raunian from the name of their terminal promontory, which runs out into the Ionian sea, and is now called Glossa, or by the Italians Linguetta. The Ceraunian mountains extended several miles along the coast from the Acroceraunian promontory, and were much dreaded by sailors from the storms they produced. Inland they were connected by an eastern branch with the mountains on the northern frontier of Thessaly. The inhabitants of the mountains were called Ceraunii. These mountains were famous in ancient poetry, and among the modern poets Shelley has celebrated them. Their present name is Khimara.

CERBERUS, in Greek mythology, the monster that guarded the entrance to the infernal regions. He was a son of Typhon and Echidna, and is represented as a dog with three heads, the tail of a serpent, and a mane composed of the anterior extremities of numberless snakes. His business was to admit the spirits of the dead into their subterranean abode, and to

Cerberus.

prevent them from leaving it. Orpheus lulled him to sleep with his lyre, and Hercules dragged him from Hades, and exhibited him to the eyes of wondering mortals.

CERDONIANS, ancient heretics, whose belief, half philosophical, half religious, was a confused mixture of Christian dogmas with oriental dualism and Gnostic ideas. Their founder, Cerdo, was a Syrian, who came to Rome about the year 139, under the pontificate of Hyginus, and developed a system, involving the two principles of good and evil and a demiurge, similar to, if not identical with, that of his contemporary Marcion. (See GNOSTICIS.) His disciples became confounded with those of the latter.

CERÉ, Jean Nicolas, a French botanist, born in the Isle of France in 1737, died there, May 2, 1810. Under the direction of the French government he greatly extended the culture of spices in the Isle of France (now Mauritius). The agricultural society of Paris published his essay on the culture of rice, and awarded him

a medal; and Napoleon confirmed him in his position as director of the botanical garden of the Isle of France, and conferred on him a pension of 600 francs. A tree of the island has been called after him *Cerea*.

CEREA, a festival celebrated at Rome every April in honor of Ceres, if the citizens were not in mourning for some public calamity. If they were, its celebration was omitted, because no person wearing mourning could be present at it. On the occasion of this festival the wanderings of the goddess in search of her daughter were represented by women dressed in white, running about with lighted torches; and games were celebrated in the circus maximus, the spectators of which appeared in white.

CEREBRO-SPINAL MENINGITIS. See SPINAL DISEASES.

CERES (called by the Greeks Demeter), the goddess of grain and harvest among the Greeks and Romans, daughter of Saturn and Rhea, and mother of Proserpine. She dwelt on Olympus till after the abduction of her daughter Proserpine by Pluto with the connivance of Jupiter. Ceres in her anger then abandoned the abode of the gods, and descended to earth to wander among men. On all who received her kindly she conferred presents and blessings; but on those who treated her inhospitably, or slighted her gifts, she inflicted severe punishments. In her grief she took neither nectar nor ambrosia, nor attended to her person; and instead of exhibiting her celestial charms, she went in the guise of an old woman. In the course of her wanderings she came at length to Eleusis, where she was hospitably received by its king, Celeus, whose wife Metanira engaged Ceres to nurse her infant son Demophon. Under the care of the goddess the child throve like a celestial. As he lay on her bosom, Ceres breathed on him, and anointed him with ambrosia; and every night, ere she put him to rest, she immersed him in the fire unknown to his parents. Ceres proposed to make the child immortal, but the folly of his mother frustrated her intention. Metanira, wondering at the marvellous growth of her son, became curious to know how his nurse treated him. Watching one night, therefore, she saw with terror and astonishment the ordeal through which her child was made to pass, and she shrieked aloud at the sight. The goddess instantly dropped the infant, and he perished in the flames; but to make up for the loss, she bestowed great favors upon Triptolemus, the other son of Celeus. Ceres then cast off her disguise, and appeared in her real character, commanding the people of Eleusis to build her an altar and a temple. A temple was raised in the vicinity, in which the sorrowing Ceres took up her abode. In the mean time the indignation of the divine mother had visited the earth with a famine. Jupiter therefore sent Iris to Eleusis to entreat Ceres to suffer the earth once more to bring forth her fruits, and to endeavor to prevail on her to return to Olympus; but with

neither request would she comply, save on condition that her daughter Proserpine should be first restored to her. All the other divinities of Olympus were successively sent to her on the same mission, but in vain. Jupiter, finding at length that it was impossible to shake her determination, sent Mercury to Erebus to beg of Pluto that he would permit Proserpine to return to the earth on a visit to her mother. The king of Hades at once complied with the request, but while announcing to his consort that she was at liberty to return to her parent, he cunningly handed her a pomegranate seed, which she incautiously swallowed. Proserpine was then conducted by Mercury to Eleusis, and delivered to Ceres. After the first burst of joy at this unexpected meeting had found vent, Ceres asked Proserpine if she had tasted aught in the nether world, to which the latter replied that she had—a single pomegranate seed. Then, said the mother, you must spend one third of every future year in the regions of darkness with your husband, but the other two thirds you will be privileged to pass on earth with me. The wrath of the goddess was now appeased, and she caused the earth to yield fruits in abundance as of old; she instructed the Eleusinian sovereign and his nobles in the mysteries of her worship; and when Jupiter sent Rhea to invite her once more to Olympus, she cordially accepted the invitation, and went thither with her daughter to take up her abode again among the immortals.—The chief seats of the worship of Ceres, besides Rome, were Attica, Arcadia, and Sicily, where she was

Ceres.

adored under the name of Demeter. The principal sacrifices offered on her altars were swine, the symbols of fertility, oxen, cows, honey, cakes, and fruits. Her image resembled

that of Juno in its maternal character, but expressed more mildness and dignity. She was represented sometimes in a sitting attitude, sometimes walking, and sometimes riding in a chariot drawn by horses or dragons. Her attire was always complete, and on her head she generally wore a garland of corn or a band of ribbon; while in her hand she held a sceptre, a bunch of corn, or a head of poppy, and occasionally a torch or mystic basket. The principal festivals of the goddess were the Thesmophoria and Eleusinia in Greece, and the Cerealia at Rome.

CEREUS, the name given to several species of cactus. The largest and most remarkable is the *cereus giganteus*, called by the Mexicans

Cereus giganteus.

saguaro, found chiefly in New Mexico and Texas, between lat. 30° and 35° N. It grows from a globular form to a tall, upright, remarkably regular cylinder, which sometimes throws out branches which at a short distance from the trunk turn and grow parallel with it. The old plants often attain a height of 60 ft. They bear a light cream-colored flower, and a fruit with a green rind and crimson pulp, pleasant to the taste.—For the night-blooming *cereus* (*cactus grandiflorus*), see **CACTUS**.

CERIGNOLA, a town of Italy, in the province and 22 m. S. E. of the city of Foggia; pop. about 18,000. The inhabitants are engaged in the cultivation of almonds and cotton, and also in linen manufactures. It has a college, hospital, and several convents. On April 28, 1503, the Spaniards, commanded by Gonzalvo de Cordova, here defeated the French under the duke of Nemours, who lost his life in the battle. In the principal streets of Cerignola is a *milliarium* recording that Trajan laid out the road from Beneventum to Brundisium at his own cost.

CERIGO (anc. *Cythera*), the southernmost of the Ionian islands, now an eparchy of the kingdom of Greece, situated at the E. entrance of the Laconian gulf, between lat. $36^{\circ} 7'$ and $36^{\circ} 22' N.$, and traversed nearly through its centre by the meridian of $23^{\circ} E.$ Its length from N. to S. is nearly 20 m., and its greatest breadth about 12; area, 106 sq. m.; pop. in 1871, 10,637. The shores are abrupt and dangerous to shipping. Storms are frequent, the currents round the island being from its peculiar position very strong, and the air is rarely quite calm. It is hilly, and abounds with streams. The soil is generally fertile; the products are corn, currants, wine, olive oil, and honey; cattle, goats, and sheep are reared. Many of the peasants resort annually to the Morea and to Asia Minor to work there during harvest time. It contains two curious natural caverns, which possess some stalactites of singular beauty. According to Pliny, the island was once called Porphyra. The ancient name of Cythera, the fabled birthplace of Venus, however, is as old as Homer. It was colonized by Phœnicians, and successively occupied by the Argives and Lacedæmonians. Its chief town in antiquity bore the name of the island. The modern chief town is Capsali, at its S. extremity.—The principal dependency of Cerigo is a little island called Cerigotto by the Italians (anc. *Ægilia*), now known as Lius to the inhabitants, lying about 20 m. S. E., midway between Cerigo and Crete, and containing about 40 families; length 5 m., breadth from 1 to 3 m. Cerigotto abounds with olive trees, and produces some fine wheat. In former times it was a noted retreat of pirates.

CERINTHUS, also called derisively **MERINTHUS** (*i. e.*, cord), a religious personage who is supposed to have come from Alexandria to Asia Minor, and to have resided at Ephesus simultaneously with St. John. He was a leader among those Gnostic Christian sects which appeared soon after the death of Christ; but, in common with the Ebionites, he considered an observance of the Jewish law essential to salvation, and believed in the notion of the vast chasm between God and the material world. He taught that it was not the Supreme God who revealed himself in the Jewish Scriptures, but a subordinate angel commissioned by the Supreme, with whom he identified himself. In this way he justified both the strictly divine character of Judaism to the Jew, and its subordination to Christianity to the Christian. Jesus he taught to be a mere man in his birth and existence until the baptism, when the Holy Ghost, which he considered to be the Christ, united itself with Jesus, and remained in this union until the crucifixion. Then, in time to leave the dying Jesus only a man again, the Christ or Divine withdrew. He attached no importance in the redemptive plan to the death of Jesus, but made salvation to depend on legal obedience. Caius, an anti-Montanistic writer, attempts to fasten upon Cerinthus the grossest

and most sensual millennialism, and even accuses him of having interpolated the Apocalypse to make it suit his chiliastic doctrines. It is true that Cerinthus taught the coming of a millennium on the earth, when Christ was to make Jerusalem the centre of his empire. This time he supposed would come after the earth had stood 6,000 years, and would be a perpetual sabbath of 1,000 years, a view which was common among the Jews of that age. His disciples were called Cerinthians, and also Merinthians. A *Historia Cerinthi* was published by Paulus (Jena, 1799).

CERITO, Francesca, commonly called Fanny, an Italian dancer, born in Naples in 1823. She made her début at the San Carlo theatre in 1836, and although only 13 was received with great enthusiasm. At Milan in 1838, and for two years at the *Kärnterthor-Theater* in Vienna, and afterward in Paris and London, the same storm of applause greeted her appearance, especially in London. She was married to Saint-Léon, well known in Paris and London as a dancer and violinist, and was separated from him in 1850.

CERIUM, a metal which was discovered simultaneously in 1803 by Klaproth, Hisinger, and Berzelius, and was so called by the last named after the planet Ceres. It occurs in association with lanthanum and didymium in cerite, allanite or thite, yttrocerite, and a few other rare minerals. Cerite, containing also lanthanum and didymium, is the most abundant of these minerals. Wöhler prepared the metal in the following manner: The brown oxide, obtained by incinerating the oxalate, is dissolved in hydrochloric acid, and the resulting chloride mixed with about equal parts of chloride of potassium and chloride of ammonium, and evaporated to expel all of the ammonia, and finally fused. The slag thus obtained is pulverized, and while still warm is mixed with sodium and projected into a crucible previously heated. The reaction is continued until the soda flame disappears. The cooled mass contains metallic pellets. Cerium has a lustre between iron and lead, and loses its polish in the air. It is malleable, ductile, and soft as lead. Its specific gravity is 5.5 at $12^{\circ} C.$ Before the blowpipe it glows to a brown oxide; heated powerfully, it explodes with scintillation. The pulverized metal takes fire at $100^{\circ} C.$ It decomposes water slightly at the boiling point; is rapidly dissolved by HCl, converted to brown oxide by concentrated nitric acid, and is easily dissolved by weak nitric acid. Its compounds have a limited use in medicine and the arts.

CERRETO (anc. *Cernetum*), a well built town of Italy, on the Apennines, in the province and 12 m. N. W. of Benevento; pop. about 5,000. It has a cathedral, a collegiate church, a diocesan school, three convents, five annual fairs, and cloth manufactories. Near its site Pyrrhus was defeated in 275 B. C. In 1688 an earthquake destroyed a great part of the town.

CERRO GORDO, a mountain pass in Mexico, 40 m. N. W. of Vera Cruz, on the national highway to the city of Mexico, where a victory was gained by the Americans under Gen. Scott, over the Mexicans under Santa Anna, April 18, 1847. The entire American force in action and reserved was 8,500; the Mexican was estimated at more than 12,000. The action lasted from sunrise till 2 P. M., and resulted in the capture of 5 Mexican generals, 3,000 men, 4,500 stand of arms, 43 pieces of artillery, 7 standards, trains of stores, and Santa Anna's private baggage and money chest. The Mexican loss in killed and wounded was computed at from 1,000 to 1,200; the American loss was 63 killed and 368 wounded. Gen. Scott paroled his prisoners, destroyed their stores, excepting one field train, and the next day advanced to Jalapa.

CERRO GORDO, a N. county of Iowa, intersected by Shell Rock river and Lime creek, and drained by Beavercreek; area, 652 sq. m.; pop. in 1870, 4,722. Clear lake is in the county. Peat is found and building stone is quarried. The McGregor and Missouri River railroad passes through it. The chief productions in 1870 were 138,592 bushels of wheat, 97,930 of Indian corn, 136,556 of oats, and 8,119 tons of hay. There were 1,515 horses, 1,435 milch cows, 1,977 other cattle, 1,914 sheep, and 1,542 swine. Capital, Mason City.

CERTALDO, a town of Italy, in the province and 15 m. S. W. of Florence, on the right bank of the river Elsa; pop. of the commune about 6,000. It was the place of residence and death of Boccaccio, who was buried here in the church of St. Michael and St. James. His sepulchre formerly stood in the centre of the church, and a more conspicuous monument was erected to him in 1503. His remains were removed in 1783, from a false interpretation of a law against burials in churches, and they were scattered and lost. His house, built of brick, with a small tower, was repaired in 1823 by the marchioness Lenzi Medici, one of his descendants, and the fragments of stone which had covered his grave were collected by her in 1826, and placed in the house, with an inscription by the poet Giordani. A monument is to be erected to him by the authorities of Certaldo on Dec. 21, 1875, the fifth centenary of his death.

CERTIORARI (Lat. *certus fieri*, to be made more certain, to be certified), a writ used for the purpose of removing the record in a particular case, whether civil or criminal, from an inferior to a superior tribunal, either as an auxiliary process to enable complete effect to be given to some other process, or as a distinct mode of appeal. In American practice it is usually employed to review the proceedings of courts not of record, and of municipal corporations in certain cases, and the determinations of special tribunals, commissioners, and other officers exercising judicial powers which affect the citizen in his rights or his property,

and acting in a summary way, or in a course different from that of the common law.

CERUTTI, Joseph Antoine Joachim, a French author, born in Turin, June 13, 1738, died in Paris, Feb. 3, 1792. He became a member of the society of Jesus and a professor in its college at Lyons, where some of his essays were at first ascribed to Jean Jacques Rousseau. In 1762 he published *Apologie de l'institut des Jésuites*, and he resided after that period in Paris, and afterward at the country seat of the duchess of Brancas, near Nancy, devoted to literature and enjoying an income of 11,000 francs, chiefly through the influence of King Stanislas. In 1788 he published *Mémoire pour le peuple français*, which became very popular; and he was employed by Mirabeau in preparing his speeches, and subsequently delivered his funeral oration. He also published a weekly journal entitled *Feville villageoise*, and was elected to the legislative assembly, but died soon afterward. The rue Laffitte was called after him till the restoration. His poem *Les jardins de Betz* was published in 1792, and a selection of his *Œuvres diverses* in 1793, the latter including his poem on chess.

CERVANTES SAAVEDRA, Miguel de, a Spanish author, born at Alcalá de Henares, Oct. 9, 1547, died April 23, 1616. His father was descended from an ancient Galician family, and his mother was a gentlewoman of refinement. Cervantes received the first rudiments of education from Lope de Hoyos, who published collections of poetry, to which his pupil, who early displayed a talent for poetical composition, contributed. One of these contributions, a pastoral poem entitled *Filena*, obtained some reputation, and attracted the attention of Cardinal Acquaviva, who in 1569 invited the young poet to accompany him to Rome. But the monotony of ecclesiastical life was little calculated to please Cervantes, and he joined in 1571 the armament commanded by Don John of Austria against the Turks. In the battle of Lepanto (Oct. 7, 1571) he received a wound, which deprived him of the use of his left hand and arm for the rest of his life; but he remained in active service till 1575, when, on his way from Italy to Spain, the galley in which he sailed was captured by Algerine corsairs. He was in their power till 1580, when his relatives and friends purchased his freedom. The whole romantic account of his captivity is found in the story of "The Captive" ("Don Quixote," part i.). He was treated with great cruelty by the Algerines, but his cheerfulness and philosophy excited the admiration of his fellow prisoners. He returned to Madrid in his 34th year, and here his literary career properly begins. The first work which he now produced was the pastoral romance *Galatea*, said to have been written in honor of his mistress, which showed a decided progress upon his *Filena*. In 1584 he married, and now had more than ever to resort to his pen to supply the wants of his family, and for

three years he wrote plays for the stage, which brought him little fame and less money. In 1588 he removed to Seville, where he acted as agent of a royal commissioner of the American fleet, and afterward as collector of public and private debts. During the latter part of 1597 he was imprisoned for about three months at Seville, for a small sum due to the government. From 1598, when he seems to have left Seville, to the beginning of 1603, when we find him established at Valladolid, we lose all trace of him. He is said to have spent the interval in La Mancha, and to have been sent there to collect rents due to a monastery; but the debtors, instead of making payment, persecuted him and threw him into prison. Here he is said to have begun "Don Quixote," laying the scene of the knight's earlier adventures in La Mancha, and making him a native of the village that treated him so ill. But no direct proof exists in support of this statement, although it is certain that he spent some time in La Mancha. We now come to the great literary performance of Cervantes. The death of Philip II. took place in 1598, and the relief which the end of his despotic rule brought to Spain was felt also in the world of letters. Cervantes could now give free vent to his opinions. In his youth at Rome he had observed in Cardinal Acquaviva's house the character of high life, and there, and subsequently in Spain, he was constantly brought in contact with persons eminent in church, state, and literature. With the camp and Moorish life he was thoroughly familiar, from his service in the navy and his captivity in Algiers. The mysteries of the stage, the characteristics of actors, were known to him from his career as dramatist. His frequent journeys had brought him into close contact with persons of all classes. His occupation at Seville and La Mancha had given him new opportunities of observation. With such a world of experience, with an inexhaustible stock of humor in his disposition, and with a love of the ideal and the heroic in his heart, he produced, in the full maturity of his genius, after having passed the 50th year of his age, his imperishable "Don Quixote." The first part was published at Madrid in 1605. In this work Cervantes hit the vulnerable point of his age. The common sense of the world had long rebelled against the mummeries of knight-errantry, and the foolish books that still spoke of chivalry of which not a vestige remained. People who had smiled when the absurdity presented itself to their minds, burst out in laughter when Cervantes gave it the finishing stroke. One day Philip III. observed from his balcony a student on the opposite banks of the Manzanares convulsed with laughter over a book. "He must either be crazy," said the king, "or he must be reading Don Quixote." This happened in 1606, after the court had removed from Valladolid to Madrid. Cervantes wrote the first part of the book probably during his residence at Valladolid,

where, after his return from Seville and La Mancha, he had taken up his residence. Although he received frequent visits from persons connected with the court and with the literary world, he was living with his wife, his two sisters, his niece, and a single female domestic, on the fourth floor of a mean house, and his pecuniary embarrassments were great. After his arrival at Madrid, while the publication of the first part of "Don Quixote" and its unprecedented success drew upon him the hostilities of those who resented the satire of his novel, he quietly occupied himself with the publication of his *Novelas ejemplares*, most of which had been written many years before, and of which he had already given a specimen in the story of the "Curious Impertinent," introduced in "Don Quixote." In 1614 he published the *Viage al Parnaso*, a satirical work, which gives a picture of the state of Spanish literature in his time, in which he describes himself as the oldest and poorest of Spanish poets. During the same year, while he was preparing for the press the second part of "Don Quixote," a continuation of the same story was attempted by a bungling plagiarist of Tarragona, whose real or assumed name was Avellaneda. This work contained invectives against Cervantes, and was probably published at the instigation of his enemies. The second part of "Don Quixote" made its appearance in the beginning of 1615, with a dedication to the count of Lemos, expressive of gratitude for kindnesses extended to him by the count. It was received with the same universal demonstrations of enthusiasm which had greeted the first part. Cervantes had at last gained the object of his ambition. He had the admiration of Europe, while even in Spain, as Lope de Vega was dead, there was no one to divide with him the literary empire. The sale of "Don Quixote" also relieved his pecuniary wants. But his health began to fail, and he had a presentiment of the close of his earthly career, indicated in the preface of his *Persiles y Sigismunda*, a serious romance modelled after the "Theagenes and Chariclea" of Heliodorus, which he prepared for the press at the beginning of 1616, though it was not published until after his death in 1617 by his widow. On April 19 he dictated to his wife the following words addressed to his friend Lemos, to whom he dedicated the work: "I have my feet already in the stirrup. I may use this expression since I feel that with one foot I stand in the grave. Yesterday I received extreme unction; to-day I resume my pen. The time is short, my sufferings grow more and more painful; my hopes grow fainter and fainter; yet I should be happy to see you before I die." Four days afterward he died, on the same day with Shakespeare.—Cervantes was of unusually fair complexion; his eyes were bright blue, his hair auburn. His countenance, handsome in youth, was spirited throughout his life. His manners were cheerful. He was beloved and

respected in every relation of life. He possessed himself the magnanimous disposition which he ascribes to his Don Quixote; but while in the knight the sentiment degenerates into folly, it bloomed in Cervantes into a genial, witty, humorous philosophy, which made him forbearing toward his enemies and amiable to his friends. *La Gitanilla* is the most interesting of his *Novelas ejemplares*. Of his dramatic compositions, his tragedy *La Numancia*, founded on the siege of that city, contains eloquent passages. His comedy *El Trato de Argel* gives a picture of Algerine life and manners, and is not destitute of interest. His miscellaneous literary productions, whatever their merit, are almost forgotten in the triumph achieved by "Don Quixote." Yet this great man was buried without any kind of distinction in the convent of the nuns of Trinity; the spot was identified in 1870 by the marquis of Molino. A common tombstone marks the place to which his ashes were removed at a subsequent period. No monument was raised to his memory till 1835, when a bronze statue of him, of heroic size, was placed in the plaza del Estamento at Madrid; and a small bust was placed in 1834 over the door of the house in the calle de los Francos where he died.—The most splendid editions of "Don Quixote" are those which appeared in 1780 at Madrid, in 4 vols., and at Paris in 1827 (Didot, 18mo). One of the best is the Madrid academy's fourth edition (5 vols., 1819), with a biographical sketch by Navarrete. The author's complete works, excepting his comedies, appeared at Madrid in 16 vols., 1803-'5, and also another edition in 1811, which however does not include his *Viage al Parnaso*. Arrieta, of Paris, published in 1826-'32 a selection of his works in 10 vols. Baudry's edition (Paris, 1840-'41) gives his complete works. A folio edition in 2 vols., profusely illustrated by Doré, was published in Paris in 1863, and in translation in London, with the plates, in 1864. Roscoe's "Life and Writings of Cervantes" appeared in London in 1839. The most eminent German translators of "Don Quixote" are Tieck (new edition, illustrated by Doré, Berlin, 1867-'8), Bertuch, and Soltan. The best English version is that of Motteux, with notes and additions by Lockhart. Among the Spanish biographers of Cervantes are Mayons y Ciscar and Pellicier; among the French biographers is Chasles (2d ed., 1866).

CERVIA, a town of Italy, on the Adriatic, in the province and 12 m. S. S. E. of Ravenna; pop. about 6,000. It is situated in the vicinity of marshes which contain the most important salt works in the country, and is the seat of a bishopric.

CERVIN, Mont. See MATTERHOEN.

CERVOLLE, or Cervole, Arnaud de, a French freebooter, born in Périgord about 1300, died in 1366. He was called *l'archiprêtre* because he held a benefice of that grade at Verona, though not in orders. He was wounded and taken

prisoner at the battle of Poitiers (1356); but having been ransomed he returned to France the next year, and raised a large band who pillaged the south of France in the name of the king, then a captive in England. He marched upon Avignon, at that time the residence of the pope, and compelled Innocent VI. to pay a large sum to save the property of the church from pillage. In 1359-'60 he was in the service of the dauphin; but resuming his career of freebooter, he forced the count of Nevers to enter into a treaty with him, and reentered the service of the dauphin, who had become king as Charles V., by whom he was appointed chamberlain. In 1365 he offered to lead his companies on a crusade against the Turks. He directed his march toward Hungary, but after traversing Champagne and Lorraine was stopped by the Germans at Metz, where he attempted to cross the Rhine. He then ravaged Alsace, but the peasants took up arms, and he was defeated in several encounters. He went back to France, and according to some accounts was killed by one of his followers; but according to others he died a natural death in Lorraine.

CESARE, Giuseppe, cavaliere di, an Italian historian, born in Naples in 1783, died there, April 15, 1856. He was at the head of the custom house of his native city till 1827, when he was dismissed. When the constitutional party came into power in 1848, he was appointed governor of the province of Terra di Bari, but tendered his resignation as soon as absolutism was again triumphant. He subsequently wrote *Arrigo di Abbate* and *Lettere romane*, historical novels. But his most important production is his *Storia di Manfredi, re di Sicilia e di Puglia* (1837), which clears Manfred's memory from the imputations of previous writers. For several years he edited a periodical entitled *Il Progresso*, and he is the author of a history of the Lombard league.

CESARI, Antonio, an Italian author, born in Verona about 1760, died in Ravenna, Oct. 1, 1828. He took holy orders, and early joined the order of Oratorians. His principal works include new editions of the *Vocabolario della Crusca* (6 vols., 1806-'9), *Bellezze della Commedia del Dante* (1824-'6), and translations of Horace, Terence, and Cicero. Four separate biographies of Cesari have been published in Florence, Verona, Padua, and Ravenna (1829-'42).

CESARI, Giuseppe, or Giuseppino, better known as cavaliere d'ARPINO, an Italian painter, supposed to have been born in a Neapolitan castle of the latter name about 1560, died in Rome about 1640. The son of a poor artist, he went as a boy to Rome, and was employed in a menial capacity by artists engaged in executing paintings for Gregory XIII., when his talent was brought to the pope's notice and procured for him a superior education and the patronage of this and succeeding popes, and he was created knight of St. John of Lateran. His frescoes and

oil paintings were exceedingly successful, and he was regarded as among the most brilliant mannerists of his day; hence he served as a target for the attacks of the *naturalisti* school of the Carracci and others. Many of Cesari's works are in Rome, including his most famous production, which is a series of frescoes from early Roman history, in a compartment of the Capitol bearing his name.

CESAROTTI, Melchior, an Italian poet, born in Padua, May 15, 1730, died Nov. 3, 1808. He was professor of rhetoric in the university of Padua, and gained a high literary reputation by his translation of Ossian into Italian blank verse (1762). He also produced a translation of Plutarch (1763), a free version of the *Iliad* (1795), a great number of academical essays, poems, and letters (included in his *Opere scelte*, Milan, 1820), and a remarkable philological work, *Saggio sulla filosofia delle lingue*. In 1807, at Milan, Napoleon made him a knight of the iron crown and bestowed a pension on him. A complete edition of his works appeared at Pisa in 1805-'13, in 42 vols. 8vo.

CESENA, a city of Italy, in the province and 12 m. S. E. of Forlì, on the Æmilian way, and on the right bank of the river Savio; pop. in 1872, 35,870. It is the seat of a bishop, has a cathedral, a seminary, a large town hall, a fountain, and a colossal statue of Pope Pius VI., who was born here. There is also the Capuchin church, containing a fine painting by Guercino, a library founded by the duke Malatesta in 1452, rich in MSS., and at a short distance the Benedictine monastery, long the residence of Pius VII., also a native of this place. A few miles S. of Cesena are extensive sulphur mines, which supply the works at Bologna and Rimini. It has a considerable trade in wine and hemp.

CESNOLA, Luigi Palma di, count, an American soldier and archæological explorer, born in Turin, Italy, July 29, 1832. In 1848, at the age of 15, he left the royal military academy at Turin, and enlisted as a volunteer in the war against Austria. He then returned to the military academy, and graduated, receiving his commission in 1850, which he resigned in 1854. Upon the breaking out of the Crimean war he reëntered the army, and served upon the staff of Gen. Ansaldi. The close of the war precluded all prospect of advancement in the Italian military service, and after a while he embarked for America, landing at New York in 1860. Here for many months he supported himself by giving instruction on the flute and lessons in French and Italian. In the spring of 1861 he married one of his pupils, a daughter of Commodore Reid of the United States navy. Soon after the outbreak of the civil war he established classes for military instruction, and not long after became colonel of the 4th regiment of New York cavalry. He was present with his regiment in 18 engagements up to the fight at Aldie, June 17, 1863, where he was wounded, taken prisoner, and

confined in the Libby prison, Richmond. In April, 1864, he was exchanged for Col. Brown, brother of the governor of Georgia, and afterward took part in the subsequent operations in Virginia. At the close of the war he was breveted brigadier general, became an American citizen, and was appointed consul at Cyprus, his place of residence being Larnaka, the principal seaport, which stands on the necropolis of the ancient Chittim of the Phœnicians, the Citium of the Romans. There in 1845 had been discovered a bass relief in black basalt, bearing a cuneiform inscription denoting that it was a present from Sargon, king of Assyria (721-704 B. C.), to his vassal, the king of Chittim. At Larnaka Cesnola heard of a massive stone vase, 7 ft. high and 11 ft. in diameter, weighing 30,000 lbs., and supposed to belong to the 9th or 10th century B. C., which the emperor Napoleon had just presented to the museum of the Louvre. His attention was soon attracted by some ancient coins and fragments of terra cotta in possession of the inhabitants of Larnaka, and he began to open some of the tombs, in which he found many objects of antique art. In 1866, while residing at Dali, 20 m. N. W. of Larnaka, a curious stone was shown to him lying several feet below the surface of the ground. He perceived that it was a part of a tomb, and making excavations he discovered that Dali occupied the site of the necropolis of the ancient Idalium, a city which ceased to exist almost 2,000 years ago, where once stood a great temple of the Venus of Cyprus. Procuring a firman from the sultan, he commenced excavations. These were continued, here and elsewhere, for three years, employing some hundreds of men, during which more than 8,000 tombs had been opened, when at last the jealousy of the Turks was aroused, and an edict from the sultan prohibited all further excavations in Cyprus. But in the mean time Cesnola had accumulated a magnificent collection of antiquities, which in 1872 was purchased for the metropolitan museum of New York; a collection which for extent and historical and artistic value is unequalled by any other of the kind in the world. The number of articles is not yet fully ascertained, but in August, 1870, when it was examined by the representative of the Russian imperial museum, there were about 13,000 articles, among which were many statues and statuettes, 1,800 lamps, 5,000 vases, 2,000 coins, 1,700 pieces of glass ware, 600 gold ornaments, 300 bronzes, and 100 inscriptions. In July, 1870, the emperor Napoleon made a large offer for the collection, then in Cyprus, for the imperial museum of the Louvre, the cost to be paid from his own private purse; but when Cesnola's acceptance of the offer reached Paris, the emperor was a prisoner. In 1872 Cesnola sent the entire collection to London for sale, where it was thoroughly examined by experts connected with the British museum, and others, and its value was fully recognized; but for

some unexplained reason the attention of the trustees of the museum was not called to it, and when Cesnola came to London he found that the knowledge of the existence of his collection was confined to a few persons connected with the museum, and no one in Europe seemed inclined to purchase. At this juncture an American gentleman made a liberal offer for it, which was at once accepted, and Cesnola's cherished desire that his collection should go to his adopted country was realized. When this became known in England, great indignation was expressed that the British museum should have lost the chance of becoming the possessor of this unique collection.—Cyprus being situated midway between Phœnicia and Greece, and having been long under Egyptian domination, its art bore the characteristics of all these countries. Perhaps the most notable single object is the colossal statue found at Golgos, 10 miles from Larnaka, in the

The Colossus of Golgos.

buried ruins of whose temple were discovered the mutilated remains of more than 1,000 statues. The colossus is 28 ft. in height. Upon the head is the helmet-shaped Assyrian cap; the long beard is in four curled plaits. It is supposed to represent a high priest, and to date from the 18th century B. C. No European museum possesses so old a statue. The oldest heretofore known were some Assyrian and Egyptian statues dating between the 8th and 14th centuries B. C. In the Cesnola collection are several other statues probably nearly as old as this colossus. The Egyptian type is well represented, one of the best preserved statues being that of a female figure holding the lotus. Among the works of the Greek type are sepulchral bass reliefs, with inscriptions; Venus with her attendants; Urania; a life-size draped statue of a priest of Venus of the Macedonian period, the head wreathed with laurel, an olive branch in the right hand, and a symbol in the

left; colossal heads with the shelly hair of early Greek art; fine statues of children and youths; and antique heads of the noblest Hellenic type. Among the marble and alabaster statuettes are Venus holding a dove, Pan playing the pipes, and women performing on the tambourine and harp. There are heads without number, Greek, Roman, and Egyptian, heads of animals, and implements of all kinds. The objects in terra cotta are numerous, some plain, others colored red or black. Venus with her attendants is a favorite subject. There are chariots and horsemen, dancing girls, grotesque masked figures, a donkey, a lioness with whelps, bulls, goats, and birds. There is a toy horse on four wheels, with a hole, doubtless for a string. This was taken from the tomb of a child, whose plaything it was perhaps long before the first Olympiad. In bronze there are statuettes of Osiris, Minerva, and Pomona; bracelets, anklets, rings, and amulets; brooches, buckles, tweezers, and mirror cases; battle axes, javelins, and arrow heads. Vases of every material, size, and shape are numerous; there are more than 1,000 different designs. Some of them are 3 ft. high and $4\frac{1}{2}$ in diameter, and, though probably 3,000 years old, are as fresh as when they came from the maker's hand. In the collection of jewelry are rings of various sorts, some with precious stones, as sapphires, carbuncles, and carnelians; clasps, beads, and spoons; mortuary plates of pure gold, which were tied upon the forehead of the dead, bearing designs in low relief of acanthus leaves, lines, scrolls, and sometimes female figures. There are gems and stones engraved with mythological and other designs, Minerva in carnelian, Mercury in jasper, Mars in garnet; heads in onyx and agate; and some fine paste cameos. The collection is specially rich in glass ware, of every shape, form, and purpose; cups ribbed and iridized, blue and ribbed, white opaque; a bowl of dark blue with iridized tints of green and purple; bottles with raised spiral lines in blue and amber, or with serpents in relief trailing over the surface. One wine cup, with a yellow ground, has feather ornaments in blue and yellow, with serpentine handles of opaque glass. The collection of coins was of great value and interest, but it was lost by the shipwreck of the vessel in which it was sent from Beyrout to England. In it were coins belonging to the best Greek period, the age of Phidias. There were coins of the Greek imperial class, among which were those of Alexander, the Seleucidæ, and a series of those of the kings of Cyprus. There was one beautiful gold coin, weighing 22 dollars, struck by Ptolemy Philadelphus. There were also Indian, Greek, Ptolemaic, Cypriote, Roman, Byzantine, Lusignanian, and Venetian coins, in gold, silver, and bronze. The inscriptions promise to be of great historical value. So recently as 1863, the duke de Luynes stated that there were only three known inscriptions in the Cypriote language, and these had not been

deciphered. In the temple at Golgos alone Cesnola found 34 inscriptions, and his whole collection contains about 100. In some respects the preservation and discovery of these Cypriote remains is more remarkable than in the case of those of Assyria. The latter were buried in the destruction of the palaces where they were found, the sites of which have been uninhabited almost ever since. But in Cyprus the sites of the tombs have been for many centuries covered over by inhabited towns, and scores of generations have lived and died on the spot, never dreaming of the treasures which lay buried a few feet below. The discovery of the buried temple of Venus at Golgos was in every way remarkable. It was known very nearly where it must have stood. Between 1817 and 1864 French archæologists expended several hundred thousand francs in excavating for it; but they dug a few miles away, and only found the site of the ancient city, now occupied by a small village. In 1866 Cesnola excavated in the same place, and of course unsuccessfully. In the winter of 1869-'70 he thought he had found the site of the necropolis, but on digging down came upon the famous temple itself, with its rich collection of antiquities. After that he purchased the ground of the village of Kuklia, 60 m. S. W. of Larnaka, which he had satisfied himself was the site of the ancient Paphos, close by the spot where Venus is said to have risen from the sea, and where was the chief seat of her worship. Here he hoped, not without reason, that he should come upon some of the famous works of Praxiteles and Lysippus, when his hopes were blasted by the edict from the sultan forbidding all further excavations in Cyprus. But the value of what he had already accomplished is beyond all price. Only a single collection of the kind at all approaches his, and that is the famous Kertch collection of Greek antiques, formed, it is said, by the royal collector Mithridates the Great, which has found a resting place in the imperial museum of the Hermitage at St. Petersburg.

CESPEDES, Carlos Manuel de, president of the revolutionary republic of Cuba, born in Bayamo, April 18, 1819. His education commenced in the Dominican convent of his native city, and was completed at the university of Havana, in which city he was admitted to the bar. Before entering upon the practice of his profession he travelled in Europe, and a previously acquired knowledge of several languages enabled him to study advantageously the customs and institutions of other countries. During his stay in Spain some remarks offensive to his country and countrymen, by a Spanish military officer, led to a duel in which his opponent was killed. When in Madrid, Céspedes was implicated with Gen. Prim in a conspiracy for the overthrow of the government, in consequence of which he was forced to leave the country. On his return to his native city in 1844 his talents and popularity soon gained for

him a large legal practice, and his influence and his outspoken censure of the Spanish colonial system at once rendered him a subject of suspicion to Spanish officials. The revolutionary expeditions of Lopez, and the uprisings of Agüero and others in Camaguey, were warmly sympathized in by Céspedes, in consequence of which he was put in prison, then forced to leave Bayamo, and reside in Manzanillo and subsequently in Baracoa. When the revolutionary movement broke out in 1868, he was chosen its supreme chief. One of his first acts was to liberate the numerous slaves upon his valuable sugar estate Demajagua; and on Oct. 10, 1868, at the head of a few poorly armed followers, he proclaimed the independence of Cuba on the field of Yara, a place rendered historic 300 years before by the execution of the Cuban cacique Hatuey by the Spaniards. On the formal organization of the republic of Cuba at Guimaro, in the Central department of the island, on April 10, 1869, Céspedes was elected president under the constitution then adopted.

CESPEDES, Pablo de, a Spanish artist and author, born in Cordova in 1538, died there in 1608. He studied the works of Michel Angelo and the great Italian colorists, and during the pontificate of Gregory XIII. acquired distinction as a painter. About the year 1577 he returned to Cordova, and became prebendary of the cathedral. He spent his vacations at Seville, where he established a museum of ancient art. Céspedes was one of the best colorists in Spain, and a successful imitator of Correggio. He was an accomplished scholar, left a poem on painting and some essays on art, and had a considerable reputation as a sculptor and architect.

CESTUS (Gr. *κεστός*, embroidered), with the ancients, a band or tie of any kind, particularly applied to the embroidered zone or girdle of Venus, famed for its power of awakening love. By this (*κεστός ἰυάς*), according to Homer, Venus captivated Mars, and Juno borrowed it in order to win the affections of Jupiter. The Romans applied the term also to the thongs or bands of leather tied around the hands of a class of boxers, from them called *cestuarii*. The Greeks used different kinds of cestus under different names. The cestus of the Roman boxers was often loaded with lead or iron, and the word in this sense is supposed by some to be a modified form of *castus*, and derived from *cadere*, to kill.

CETIGNE. See CETTIGNE.

CETTE, a fortified seaport of France, in the department of Hérault, 17 m. S. W. of Montpellier; pop. in 1866, 24,177. It is built on the slope and at the foot of a hill (anc. *Mons Setius*), on a tongue of land between the lake of Thau and the Mediterranean, which are united by a canal that traverses the town and terminates in the harbor. Next to Marseilles, Cette is the most important commercial port in S. France. It is an outlet of the southern wine

districts; the canal du Midi connects it with Bordeaux, and the canals des Étangs and de Beaucaire and the Rhône connect it with Lyons; and it is the termination of the Paris, Lyons, and Mediterranean network of railways. The great northern railway connects Cete with Bordeaux and Toulouse, and the Lyons-Mediterranean railway with Montpellier, Nîmes, and Tarascon. There are steamers to Algiers, Marseilles, Cannes, and Nice. The town, founded by Louis XIV., owes its rise to the mole, which was commenced in 1666, and which shelters the harbor on the south. At its end, on the left of the entrance to the harbor, is Fort St. Louis, which is surmounted by a lighthouse. A breakwater in front of the harbor prevents the accumulation of mud, and the other side of the harbor is formed by a pier, on the extremity of which rises Fort St. Pierre, completing, with a citadel on the opposite cliff, the defences of the port. The harbor has a depth of from 16 to 19 feet, and is safe in any weather. Cete is the centre of an extensive coasting and foreign trade. The entrances in 1870 were 2,613 vessels, of which 692 were steamers; the clearances, 2,624, of which 692 were steamers. The exports amounted to \$5,414,725, of which wine formed \$3,462,063; the imports were \$13,177,199, of which timber, staves, grain and flour, brimstone, and codfish were the leading articles. There is a large manufacture of so-called Madeira wines, produced by the mixture of French and Spanish wines and brandy. The salt works in the neighborhood are the most important in France. The fisheries of sardines, cod, and oysters employ some hundreds of vessels. There are also glass works, extensive ship-building yards, and establishments for the production of sulphates of soda, magnesia, and potash by evaporation from sea water. Casks, corks, soaps, sirups, grape sugar, and perfumes are made there. Cete possesses a tribunal of commerce, various courts of justice, an imperial hydrographic school, a communal college, a public library, and a theatre, and is a favorite resort for sea bathing. It was laid out in 1666 after Colbert's designs, at a great cost, and the works of the harbor were executed by M. Riquet, the engineer of the canal du Midi. In 1710 a small British force, designing to effect a junction with the insurgents of the Cévennes, took possession of Cete, but was driven back after a few days.

CETTIGNE, or **Cetigne** (Slavic, *Tzetinie*; Ger. *Zettinje*), the capital of the principality of Montenegro, situated on a hill about 10 m. E. of the Adriatic, and 37 m. N. W. of Scutari; pop. about 700. It is fortified, has a convent and a school, and on a plain below the village is the government house of the principality. It carries on some trade with Dalmatia, the nearest port being that of Cattaro, and has a powder mill.

CETUS (the whale), a large constellation of the southern hemisphere, containing 97 stars,

and said to represent the monster which was going to devour Andromeda. Its brightest star, named Menkar, comes on the meridian at 8 o'clock in the beginning of January.

CEUTA (anc. *Septa*; Moorish, *Sebta*), a town and fortress on the N. coast of Fez, Morocco, belonging to Spain, and included in the province of Cadiz; pop. about 7,000. It is situated at the E. entrance of the strait of Gibraltar, where a small peninsula juts out in a N. N. E. direction exactly opposite Gibraltar, being joined to the mainland of Africa by a narrow but well fortified isthmus, on which the town is built. The N. E. of the town is almost entirely occupied by the Monte del Hacho (the anc. *Abyla*), which is a spur of the range of mountains called Jebel Zatout (anc. *Septem Fratres*). On the highest part of the mountain stands the citadel of Ceuta, with a garrison of 5,000 men. The town is well built, gives title to a bishop who is suffragan of the archbishop of Seville, and is the seat of a military governor and of a royal court of justice, and the chief of the Spanish *presidios* or convict establishments on the African coast. The other *presidios*, comprising in all an area of 32 sq. m. and a convict population of about 11,000, are under the charge of the governor of Ceuta. The town is clean and paved in a mosaic pattern, has a cathedral, several convents, and a house of mercy founded in 1498. The harbor is unsafe, and there is little trade.—Ceuta was a town of Mauritania Tingitana under the Romans. In 1415 John I. of Portugal wrested it from the Moors, who in their invasions of Spain first set out from Ceuta. In 1580 it passed with Portugal to Philip II. of Spain by conquest, and was formally ceded by Portugal to Spain by the treaty of Lisbon of 1668. Afterward it was several times unsuccessfully besieged by troops from Morocco. At the beginning of this century it was held for a short time by the English.

CÉVENNES, a mountain range of France, which separates the valleys of the Garonne and the Loire from those of the Saône and the Rhône. In its widest sense it extends over more than 300 m., and is divided into the S. and N. Cévennes. The former, which contain extinct volcanoes, assume successively the names of Black, Espinouse, Garrigues, and Lozère mountains, and form the group of Gévaudan, several branches of which diverge in various directions; the most important, running N., connects with the cluster of mountains of volcanic origin known as the mountains of Auvergne. The highest points of the Cévennes are Mont Mezin, 5,790 ft., and Mont Lozère, 4,870 ft. The northern are of less importance, and are scarcely more than hills, under the names of Vivarais, Lyonnais, Forez, and Charolais mountains. They connect with the Vosges through the hills of Côte d'Or, the plateau of Langres, and the Faucilles mountains. Several rivers rise in this chain, the most important of which flow N. W. or W. to

the Atlantic, such as the Loire, the Allier, the Lot, &c. The Hérault and the Gard, which run in an opposite direction to the Mediterranean and the Rhône respectively, are but short streams.—Cévennes was also formerly the name of a French province, which formed the N. E. part of Languedoc, and was divided into Gévaudan, Velay, Vivarais, and Cévennes proper, the respective chief towns of which were Mende, Le Puy, Viviers, and Alais. It is now included in the departments of Haute-Loire, Lozère, Ardèche, Aveyron, and Gard.

CEYLON, an island in the Indian ocean, belonging to Great Britain, between 50 and 60 m. from the S. extremity of Hindostan. It is separated from the mainland by the gulf of Manaar and Palk strait. Its limits extend between lat. $5^{\circ} 55'$ and $9^{\circ} 51'$ N., and lon. $79^{\circ} 52'$ and $81^{\circ} 55'$ E. It is oval, nearly pear-shaped, extending in length N. and S.; is 266 m. long; greatest breadth $140\frac{1}{2}$ m., average breadth about 100 m.; area, 24,705 sq. m.; pop. in 1871, 2,405,287. On the N. W. its shores are low and sandy, and a succession of bold rocks, stretching across the gulf of Manaar, together with the holy island of Ramisseram, nearly connect it with the mainland. From its position and geological character, Ceylon appears to have been once part of the mainland. The straits which separate the island from it are navigable only for small vessels. The main western channel has been widened and deepened by the British government, and is now traversed by vessels of 300 tons, thus much facilitating the coasting trade, and materially shortening the voyages between the Malabar and Coromandel coasts. The W. and S. coasts are low, much indented, and lined with cocoanut and other palms. Numerous small harbors are found along this shore. The E. coast, from Matura to Trincomalee, is an arid but bold and precipitous shore. On these sides the line of coast is of varying depth, from 30 to 80 m., surrounding the mountain ranges which form the centre of the island. The N. shore is a vast arid and sandy plain, teeming with swamps and jungle. The pearl oyster banks are on the W. coast, and when the fisheries are opened, vast but temporary towns are suddenly formed and as suddenly abandoned, by pearl fishers and speculators in pearls. The island possesses two excellent harbors, Trincomalee on the N. E. and Point de Galle on the S. coast. Colombo, the capital, on the W. coast, has but an open roadstead; and Point de Galle is the principal port of the island. There are several smaller harbors, suitable for coasting vessels. The roads of Colombo afford safe but stormy anchorage; but at particular seasons, especially June and October, communication with the shore is difficult and hazardous. Other harbors are Batticaloa, Matura, and Caltura on the E. and S., and Negumbo, Chilario, Calpentyn, Manaar, and Point Pedro on the W. and N. W. coasts. There are numerous small islets along the coasts, and two considerable peninsulas, Jaffnapatam on the N. W. and Calpentyn on

the W.—The mountain ranges of Ceylon rise in the centre of the southern or broader part of the island. The general direction of the chief ranges is from N. to S.; but several ranges branch off in various directions. Several peaks or summits rise to a great height. Pedrotalagalla, an abrupt peak, the highest on the island, is 8,280 ft. high, and Adam's peak, 7,420. The greater part of the fertile and highly cultivated hillside country ranges between 2,000 and 4,000 ft. high. The plain of Newera Ellia, the sanatorium of the island, is at an elevation of 6,210 ft. Candy, the capital of the central province, and former capital of the independent kingdom, is 1,678 ft. above the sea. Adam's peak is the most remarkable summit on the island. It is resorted to by Mohammedan and Buddhist pilgrims, being one of their holy places. (See ADAM'S PEAK.)—The island has numerous small rivers and brooks, but no considerable streams. Few are navigable for

Adam's Peak.

more than a few miles from their mouths. The chief is the Mahavelli Gunga, which rises in the southern highlands, flows N., and empties into the bay of Trincomalee; it is nearly 200 m. long. The next, the Kalani Gunga, has its source at the foot of Adam's peak, and falls into the sea near Colombo. There are no lakes of importance in the interior, but several extensive lagoons on the E. coast. Some of these are connected by canals and natural streams, and are used for purposes of commerce. Artificial lakes, the relics of native undertakings of former days, are found. One is still in good condition, and serves to irrigate a large district between Candy and Trincomalee. It is 20 m. in circumference, and its waters are imprisoned in the valley which contains them by a vast embankment 60 ft. wide at top. Another, now in ruins, appears to have been kept in bounds by a wall of masonry 12 m. long and 160 ft. thick. These collections of water were

formed by damming the natural outlets of the mountain streams at the mouths of extensive valleys. They were of great service to the country when more densely populated and thoroughly cultivated than now.—A belt of gray and black sandstone and coral formations nearly encompasses the island. The rocks of the interior are mostly primitive, consisting of granite, gneiss, large veins of quartz, &c. Limestone occurs only in Jaffnapatam and the northern districts. The surface soil is mostly sandy. The soil of the cinnamon plantations near Colombo is perfectly white, and consists of pure quartz. Ores of iron, lead, tin, and manganese are found in the interior. Plumbago of excellent quality occurs. Quicksilver mines exist, and were formerly worked by the Dutch. The most valuable gems are the ruby, sapphire, amethyst, cat's-eye, and carbuncle. Cinnamon stones and garnets exist in great plenty. Iron ore is worked up by the Cingalese in a rude way, but with considerable success, the iron being equal in temper to the best Swedish. Salt, which is found in beds, is a monopoly of the government and affords a considerable revenue.—The climate of Ceylon differs little from that of the neighboring part of India; but the island is much healthier than any portion of southern India. The N. E. and S. W. monsoons mark the changes of the seasons, which occur on the seacoasts in May or June and October or November, bringing with them heavy thunder storms. The highest temperature at Colombo is about 87°; on the coffee estates it is stated at between 56° and 80°; and in the high valley of Newera Ellia, during January and February, the mercury falls as low as 31°. The prevailing diseases of the country are cholera, dysentery, and fevers. Elephantiasis is a disease peculiar to the natives. The beriberi (*hydrops asthmaticus*) is another disease nearly peculiar to the island.—The zoölogy of Ceylon bears a general resemblance to that of the adjoining mainland. The elephants are of a less tractable species than those of India and Africa. They exist in great numbers in the interior, and commit frequent ravages upon the native fields. They are often trapped in vast kraals, into which they are driven by a great assemblage of natives. Of late years English huntsmen have killed very many of them for sport. According to Sir J. E. Tennent, not one elephant in a hundred is found with tusks in Ceylon. Oxen of small size and buffaloes are used as draught animals. There are four species of deer and a great variety of monkeys, as well as the jackal, squirrel, porcupine, wild boar, bear, and one species of ant-eater. Leopards are met with, but they are not numerous and seldom attack man. Of birds there are all the varieties common to the tropics. There are several species of serpents, including the venomous tic polonga, the cobra de capello, and gigantic pythons, as well as ten species of tree snakes. Crocodiles are found in the rivers, scorpions and huge spiders

in the houses, and lizards in the woods. Fish are of many varieties, and in great abundance, some of excellent quality for eating.—The vegetable products are numerous and valuable. There are 416 known varieties of valuable woods, of which 33 are used for house, furniture, and ship building. Among these are satinwood and ebony. The coconut palm is altogether the most useful tree to the natives. It grows readily without cultivation, is not limited to one soil, and every part of it is made use of by the Cingalese. The fruit, when green, supplies food and drink; when dry, oil; the sap is made into toddy and arrack; the fibrous husk furnishes ropes, nets, and matting; the nutshells form household utensils; the plaited leaves serve the same purpose, and also for thatch; the dried flower stalks serve as torches, and the large leaves as fences. The trees bear from 50 to 100 nuts per annum, and often grow so near the water's edge that the waves wash their roots. There are several other varieties of palms, one of which furnishes in its wide-spreading leaves the umbrella which is a notable article of Cingalese use. The fruit of the betelnut palm is exported. Besides native fruits, which are not numerous, various European and Indian fruits have been introduced latterly under the auspices of English planters, who have formed an agricultural society. Cinnamon, which grows wild in the forests, is cultivated to a large extent, arrives at a high state of perfection, and has long been an important article of export. Its cultivation was formerly a government monopoly, but was thrown open to the public in 1833. When growing wild, the cinnamon plant attains a height of 20 to 30 ft.; cultivated, it is not allowed to grow so thriftily, the young shoots giving the finest bark. Coffee flourishes, and has latterly been the chief article exported to Great Britain. Rice, cotton, tobacco, and pepper are also cultivated. Breadfruit grows abundantly. The sugar cane does not succeed. There are two rice harvests annually, January to March, and August to October.—The population (exclusive of Europeans) consists of four classes: the native Cingalese; Moors, who are Mohammedans of Arab descent; Veddahs, a savage, perhaps aboriginal race, inhabiting the mountain fastnesses; and the Malabars and other Hindoos, who immigrated from the neighboring continent. The religion of Buddha is the dominant native creed. There are four great political castes, and 24 minor ones. The Cingalese are singularly mild and inoffensive in their manners, and make very poor soldiers. Their genius seems to be for agriculture and for peace. Christianity was introduced in the 6th century, but subsequently died out, and was revived by the preaching of St. Francis Xavier in the 16th century. The mission was very successful; a Jesuit college was established, and the province of Jaffna became almost wholly Christian. The Dutch banished the Catholic priests and nuns, and gave employment to no unbaptized

native; thus the population connected with the Dutch Reformed church rose to 425,000; but after the cession of Ceylon to Great Britain the Dutch church soon died out. The Roman

Cingalese.

Catholic church has at present two vicariates apostolic, Colombo and Jaffnapatam, with a membership of about 140,000, and about 260 churches. Protestant missions have been established by the church of England, which has a bishop at Colombo, by the English Wesleyans and Baptists, and by the American Congregationalists. The aggregate membership of these churches is about 3,000. The missionary efforts of the Catholics and Protestants induced the Buddhists to form in 1860 a society to propagate the doctrines of Gautama by itinerant preaching, the press, and colportage. Education is making great progress. There were in 1870 about 900 schools in the colony, attended by 30,000 pupils, of whom about 1,500 were girls. The schools are partly free public schools supported by the government, and partly church schools established by the missionary societies, and aided by money grants from the governments. The most important government institutions are the Colombo academy, consisting of an upper and lower school, and a normal training school in the same city.—Ceylon is what is known as a crown colony, the English sovereign possessing, through the governor, direct control of the colonial legislation. It is divided into six provinces, which, with their population in 1871, are as follows: Western province, 776,930; Central, 494,626; Southern, 399,452; Northern, 340,169; North-western, 276,033; Eastern, 118,077. The government is administered by a governor (in 1873 William Henry Gregory, appointed in December, 1871), with an executive council of 5 and a legislative council of 15 members. All

questions relating to the revenue of the island must receive the sanction of the governor before they can be debated in the legislative council. In 1871 the revenue was £1,121,679; expenditure, £1,064,184. The public debt was £700,000.—The pearl fishery was long a source of annual income to inhabitants and government. After lying untouched from 1837 to 1855, the banks, which are situated off the western parts of the coast, have again yielded profitable returns. Rice is the staple grain. The cultivation of coffee dates only from 1834; the average production is from 6 to 9 cwt. per acre. In 1870 there were exported 921,506 cwt. of plantation, and 132,524 cwt. of native coffee. The yield of cinnamon varies, according to the mode of cultivation, from 50 to 500 lbs. per acre; in 1870 there were exported 20,716 bales, of 100 lbs. each. The planting of the cocoanut palm, for the sake of the oil, has within a few years been successfully carried on by Europeans; in 1870, 13,566 cwt. of oil were exported. From Great Britain are imported cotton manufactures, hardware, glassware, metals, tools, beer, wine, &c.; from India, especially grain. The arrivals of vessels in the ports of Ceylon in 1868 were 3,257, of 614,947 tons; clearances, 3,182 vessels, of 631,647 tons. The value of exports in 1871 was £3,804,000 (to the United Kingdom, £2,633,000), and of imports £4,634,000 (from the United Kingdom, £1,462,000). Both imports and exports have enormously increased since 1850, in which year the imports were only £1,488,000, and the exports £1,246,000. The increase of imports has been most considerable in grain; that of exports, in coffee. The banking business is conducted by branches of the Oriental bank of London and the Mercantile bank of Bombay, the former establishment possessing the privilege of issuing notes of 10s. and upward. The foreign trade of Ceylon is carried on mainly by European firms, the native houses confining their transactions to British India, and the small native dealers, called chitters, to their connections with Madras and Bombay merchants. Great exertions are made for improving the public roads; in 1868 more than £230,000 were expended on them. Colombo and Candy have been since October, 1867, connected by railway, and nearly all the important places of the island by telegraph.—Ceylon was known to the Greeks and Romans under the name of Taprobane. Pliny relates that Onesicritus, a captain of Alexander the Great, first circumnavigated it, and thus discovered it to be an island. Before this it was supposed to stretch indefinitely south. Serendib was a former name of the island. *Zeylan*, of which Ceylon is a corruption, is said to be from *zibal*, Hindostanee for lions. The Cingalese annals profess to contain a historical record of events for 24 centuries back. These, and the extensive ruins of ancient cities (see POLLANARRUA), show that it was thickly settled by a people of energy and civilization,

even at that remote period. An Indian conqueror is said to have introduced caste about 550 B. C. The island was visited by traders at an early period, by Marco Polo in the 13th and by Sir John Mandeville in the 14th century. Dom Lorenzo Almeida, a Portuguese, visited it in 1505, and was hired by an annual payment of cinnamon to defend its shores against Arabian pirates. He found it divided into seven separate kingdoms. Through Almeida the Portuguese obtained footing upon the island, and held it for 150 years. Capt. Knox, an Englishman, fell into the hands of the Candians in the 17th century, and in 1681 published an interesting account of his 20 years' captivity. In 1656 the Dutch expelled the Portuguese. In 1795-'6 the British expelled the Dutch. The island at first belonged to the East India company, and was a part of the Madras presidency, but in 1802 reverted to the British crown. In 1815 the Candians, whose territory occupied the entire interior of the island, and who were independent of foreign rule, called upon the British to depose their tyrannous prince, thus offering a convenient opportunity for the annexation of this valuable territory. In 1817 an extensive rebellion was successfully put down. In 1843 and 1848 there were minor attempts at rebellion.—See Sir Samuel W. Baker's "Rifle and Hound in Ceylon" (London, 1853), and "Eight Years' Wanderings in Ceylon" (1855); Sir James Emerson Tennent's "Ceylon, an Account of the Island, Physical, Historical, and Topographical" (6th ed., 1864), and "Natural History of Ceylon" (1861); and Ransonnet, "Ceylon" (1868). (See CINGALESE LANGUAGE.)

CEZIMBRA, a seaport of Portugal, province of Estremadura, on the Atlantic, 20 m. S. of Lisbon; pop. about 5,000. There are considerable fisheries here. Under its walls Alfonso Henriquez in 1165 defeated the Moorish king of Badajos. About 8 m. W. of Cezimbra is the pilgrimage chapel of Nostra Senhora do Cobo, on the crest of Cape Espichel, the Promontorium Barbaricum of the Romans, from which there is a fine view northward of the rock of Lisbon, and southward of the whole of the Arrabida promontory between the mouths of the Tagus and the Sado, and of almost the whole W. coast of Alemtejo.

CHABAS, François Joseph, a French archæologist, born at Briançon in 1817. He early devoted himself to scientific studies, and acquired eminence as one of the highest recent authorities on Egyptology. His first publication appeared in 1856, and his principal works are: *Le papyrus magique Harris* (1861); *Voyage d'un Égyptien en Syrie* (1866); *Les pasteurs en Égypte* (1868); and *Études sur l'antiquité historique* (1872). The last named work embodies his researches undertaken in consequence of the accidental discovery in 1865 of several flint knives in the bed of the Saône, and his subsequent extensive excavations in the same locality. Differing in opinion from most other archæologists, he assigns a historical ex-

istence to many incidents hitherto reputed prehistoric, and avers that science has not yet demonstrated a very high antiquity for man antecedent to the historic period. His work comprises Egyptological speculation up to the present day, and his researches derived from original sources are presented in a series of disquisitions on the chronology, metals, implements, and arms, and on the knowledge of the horse and the camel of the ancient Egyptians. The most suggestive chapter treats of the nations known to the Egyptians, and the book closes with a consideration of so-called prehistoric localities, and with a description of the author's discoveries in the valley of the Saône.

CHABERT, Joseph Bernard, marquis de, a French navigator and astronomer, born in Toulon, Feb. 28, 1723, died in Paris, Dec. 1, 1805. He entered the naval service in 1741, became a member of the French academy in 1758, and in 1781 was made commander of a squadron. He lost his sight through over study in 1800, and in 1804 was appointed a member of the board of longitudes. He was an accurate observer and industrious hydrographer. He planned and executed maps of the shores of North America, the Mediterranean, and especially of Greece. One of his principal works is *Voyages sur les côtes de l'Amérique Septentrionale* (Paris, 1753).

CHABLAI, a former administrative division of the province of Annecy, Savoy, now forming the arrondissement of Thonon, in the department of Haute-Savoie, France; area, 356 sq. m.; pop. in 1866, 60,193. The Romans raised great numbers of horses in its fine mountain pastures, whence its name Caballica Provincia or Caballicus Ager, corrupted to Chablasium and Chablais. It formed part of the kingdom of Burgundy, and in the 11th century was given by the emperor Conrad to Humbert, first count of Savoy, one of whose descendants became count of Chablais in the 14th century. Under the first French empire it formed part of the department of Leman; in 1814 it was restored to Sardinia, and in 1860 was ceded with the rest of Savoy to France.

CHABLIS. See FRANCE, WINES OF.

CHABOT, François, a French revolutionist, born at Saint Geniez in 1759, died in Paris, April 5, 1794. He was the son of a cook, became a Capuchin friar, was appointed grand vicar of the bishop of Blois, and in 1791 was sent to the legislative assembly. He became conspicuous by his democratic zeal, and declared that "the citizen Jesus Christ was the first *sans-culotte*." Chabot was the first to apply to well dressed young men the name of *muscadins*; in his person and dress he affected great neglect. He was a member of the convention in 1792, and edited the *Journal populaire*. At length, however, he lent himself to the machinations of the enemies of the revolution. An Austrian banker, Junius Frey, one of their most active agents, gained him

over by giving him his sister Leopoldine in marriage, with a dowry of \$40,000. Chabot became implicated in various suspicious operations, and was guillotined.

CHABOT, Philippe de, a French general, born toward the end of the 15th century, died June 1, 1543. Descended from an ancient family of Poitou, he was brought up with Francis I. He bravely defended Marseilles in 1524, and was made prisoner at Pavia in 1525. Appointed admiral immediately after his release, he was sent to Italy in 1529 to negotiate the ratification of the treaty of Cambrai by Charles V. Made commander-in-chief of the forces in Savoy in 1535, he effected the conquest of part of that country and of Piedmont, but was censured for not following up his victory. On his return to France charges of frauds upon the national treasury were brought against him by the constable de Montmorency. Found guilty and imprisoned, he was soon afterward pardoned by the king at the solicitation of the duchess d'Étampes, and reinstated in his position after the disgrace of Montmorency. He is said to have been the first to suggest the project of colonizing Canada. A collection of his letters written in 1525 is in the national library of Paris. A monument, dedicated to him by his son Léonor, is now in the Louvre.

CHABRIAS, an Athenian general, killed in the harbor of Chios in 357 B. C. In 392 he succeeded Iphicrates in the command of the Athenian forces before Corinth, was afterward sent to chastise the Æginetans for depredations on the coast of Attica, and assisted Evagoras in Cyprus, and Acoris in Egypt, against the Persians. In 378 he commanded the army which the Athenians sent to the aid of Thebes against the Lacedæmonians, under Agesilaus, on which occasion he saved his troops from impending defeat by commanding them to await the attack of the enemy with pointed spear and shield, resting on one knee. A statue of him in this position was erected to his honor in Athens. In 376 he won an important victory over the Lacedæmonian fleet off Naxos. A few years later he went on his own account to Egypt, where he commanded the naval forces of Tachos, then in rebellion against the Persians, whose cause, however, after the desertion of the Spartans, he gave up as hopeless. After his return to Athens, he took part in the expedition against Thrace at the outbreak of the social war. At the siege of Chios his vessel was the first to enter the harbor, but becoming isolated and disabled was soon abandoned; he alone refused to save his life, and fell fighting. He was the last of the great Athenian generals. Demosthenes said of him that he conquered 17 cities, took 70 vessels, made 3,000 prisoners, and enriched the treasury of Athens with 110 talents. One of his apophthegms was that an army of stags led by a lion is superior to an army of lions led by a stag. His life was written by Cornelius Nepos.

VOL. IV.—15

CHABRILLAN, Céleste Vénard, countess de, a French author, born in Paris, Dec. 27, 1824. Driven from her home by the brutality of her stepfather and the ill treatment of her mother, she became an actress and a circus rider, and was disreputably noted under the name of Mogador. In 1854 she published *Adieux au monde, mémoires de Céleste Mogador* (5 vols.), which was suppressed, as well as the second edition (4 vols., 1858). She married in 1853 the count Lionel de Chabrilan, who became consul at Melbourne. After his death (Dec. 29, 1858) she returned to Paris, and was an actress and manager of the Folies Marigny theatre (1862-'4), where some of her plays were performed. She has written several novels, including *Mémoires d'une honnête fille* (1865).

CHABROL DE CROUZOL, André Jean, count, a French statesman, born at Riom, Nov. 16, 1771, died at Chabannes, Aug. 7, 1836. He took orders, and during the French revolution was imprisoned for refusing to preach in favor of the secularization of the clergy. He was set free in 1795, entered political life, and after holding several minor offices was made in 1812 intendant general in the Illyrian provinces. Returning to Paris in 1814, he was appointed councillor of state by Louis XVIII., and in November made prefect of the department of the Rhône, taking up his residence at Lyons. In 1816 he was led into measures of arbitrary severity by the supposed discovery of a conspiracy in the city; and he was recalled by the government, but soon after received the office of under secretary in the ministry of the interior. In 1820 he was elected a deputy from Puy-de-Dôme, and in January, 1821, he was made director of registry and public lands. In 1824 he became a peer of France and was made minister of marine, distinguishing his administration of the office by many useful reforms. He was minister of finance in the cabinet of Polignac in 1829, and retired from political life in May, 1830.

CHACHAPOYAS (sometimes called SAN JUAN DE LA FRONTERA), an inland town of Peru, capital of a province of the same name and of the department of Amazonas, 410 m. N. of Lima; lat. 6° 18' S., lon. 77° 25' W.; pop. about 6,000. It is situated on the banks of a river of the same name, a tributary of the Marañon, which waters the province. The surrounding districts produce tobacco and cotton, fruits, the European cereals, vegetables, &c., in abundance; cattle are raised in great numbers; and the people are chiefly occupied in agriculture, and the manufacture of leather, trunks, chairs, cigar cases, &c.

CHACO, El Gran (the Great Chaco), a vast and for the most part unexplored region of South America, extending along the centre of the continent from the left bank of the Rio Salado N. to about lat. 20° S., where it is lost in the Chiquito plains in Bolivia; and from the banks of the Paraguay W. to the E. limits of the mountain region of the Argentine Republic.

It thus forms the continuation of the great pampæan plains which begin far south in Patagonia, and reach N. to the Salado. Owing to the nature of its climate and soil, the Chaco is naturally divided into two distinct portions, northern and southern. The northern, watered by plenteous rains and traversed by a river of considerable magnitude, the Pilcomayo, presents the usual features of intertropical countries; it is densely wooded, and clothed in immense tracts with a luxuriant growth of grass, with here and there wide-spreading marshes, which rarely become entirely dry between the periodical floods. Here almost all kinds of spontaneous tropical vegetation are represented. The southern division may be considered as one vast desert, generally unfavorable to vegetable growth, and presenting here and there some rare specimens of dwarfish spiny plants; but the aridity of the soil is due to the lack of moisture so common in all South America below lat. 24° S. and W. of the Plata and Paraguay. This may be overcome by artificial irrigation, and several prosperous colonies have of late years been formed in that region. The whole of the northern portion, which belongs to Bolivia, is, with the exception of a settlement established in 1872 in the N. W. corner of the territory by the Bolivian government, the undisputed home of uncivilized Indians; while the southern, besides the colonies of whites already mentioned, is divided between nomadic and semi-civilized Indians, the latter having abandoned their predatory habits and established themselves by families in determined localities in imitation of the whites. The animal life in the Chaco differs in few respects from that of the neighboring portions of the Argentine and Bolivian republics. Capybaras or carpinchos, and the various other larger mammals, abound on the banks of the rivers; there are numerous species of serpents and hideous venomous spiders of immense size; and myriads of small birds of endlessly varying plumage enliven the forests.

CHÆRONEA, a town of Bœotia, on the Thermodon, a small tributary of the Cephissus, near the frontier of Phocis, renowned for the battle in which Philip of Macedon defeated the Athenians, Corinthians, and Thebans in 338 B. C. This victory was largely due to Alexander, then a youth of 18, who commanded the left wing of his father's army, and broke the sacred band of the Thebans by the weight of the Macedonian phalanx. It made Philip master of Greece. The Athenians lost 1,000 killed and several thousand prisoners. Another battle was fought here in 86 B. C., and won by Sulla over the army of Mithridates, king of Pontus, under Archelaus. Some remnants of the ancient town are still visible at the village of Capurna, such as a theatre on the mound of the slaughtered Thebans, an aqueduct, and a broken marble lion, undoubtedly that mentioned by the historian Pausanias as having been placed above the grave of the Theban dead.—Chæronea

was the birthplace of Plutarch, and the last years of his life were spent there.

CHÆTODON, a genus of spiny-rayed fishes, with compressed and scaly body, so named from their closely set rows of bristle-like teeth. The family to which they belong was formerly called *squammipectnes* from the scaly character of the dorsal and anal fins; the mouth is small. They abound in tropical waters, on rocky shores, and are of brilliant colors, black, blue, green, and yellow being the

Chætodon rostratus.

prevailing hues; their flesh is good eating. In this genus, of a family containing nearly 20 genera and 150 species, the *C. rostratus* (Bl.), of Java, is remarkable for its faculty of ejecting drops of water from its elongated snout, so as to hit insects on the plants growing in the water and thus secure them as food; this it does with great precision. It is of a silvery hue, with five brownish bands.

CHAFFINCH (*Fringilla œolebs*, Linn.), one of the most common and most beautiful of the passerine family of birds, a native of Europe. The color of the bill varies according to the season from a blue to a pale reddish brown; the eyes are hazel; the forehead black; upper part of the head and hind neck grayish blue; back reddish brown; fore neck and breast purplish red or dull pink; rump yellowish green; the larger wing coverts black, the secondary tipped with white, the smaller black and grayish with white spots; the quill feathers white at the base and along the inner margin; the tail brownish black, the exterior feather obliquely marked with white, including the middle of the outer web and the terminal third of the inner, the next slightly margined with white internally, and tipped with the same on the inner web; the middle feathers brownish gray, blackish along the shafts. The female has the upper part of the head and the back light grayish brown; the rump yellowish gray. Young like the female,

with the tail paler. The variations from these colors are slight, though the tips of the feathers become considerably worn, giving a brighter appearance to the plumage of the head, back,

Chaffinch (*Fringilla œlebs*).

and breast. Length of the male $6\frac{1}{2}$ inches; extent of wings $11\frac{1}{2}$ inches; bill $\frac{1}{2}$ inch; tarsus $\frac{3}{4}$ inch; the female is a trifle smaller. It is a permanent resident in Great Britain, though in corresponding latitudes on the continent it migrates southward. Its notes are monotonous, generally *twink, twink*, repeated three or four times; hence its provincial name of *twink*; it is almost constantly heard in the lanes and gardens from May 1 to the middle of June. In summer they live chiefly on insects, with which they feed their young; in winter they become gregarious and frequent the fields, farm yards, and roads in search of seeds and grain, to aid the digestion of which they swallow smooth particles of gravel. Their flight is rapid, with frequent undulations; on the ground they move with short leaps. The nest is neatly constructed of moss, lichens, wool, feathers, and hair, and is generally of such a gray color as to be seen with difficulty in the cleft of the lichen-covered trees. The eggs are four or five in number, about three fourths of an inch long, of a purplish white or pale reddish gray color, with a few spots and lines of reddish brown. The chaffinch is one of the most familiar birds, and, with the sparrows and buntings, in the winter will come in flocks around the doors of the farm houses. They prepare to breed in April, and hatch their first brood by the middle of May, and a second by the end of July. They are much esteemed in Germany as song birds, and are occasionally seen as parlor ornaments elsewhere.

CHAGRES, a river of the United States of Colombia, rising in the mountains about 40 m. N. E. of Panama. It flows first W., then curves abruptly to the N. W., and falls into the Caribbean sea at the town of the same name, which it intersects. Its whole course is about 120 m., through a country of remarkable fertility; its principal tributary is the Trinidad, and there are one or two others of inconsiderable magnitude; and its depth from the junction of the Trinidad gradually

increases from 16 to 30 ft., until it reaches the town of Chagres, a distance of less than 10 m. The swiftness of its current and a number of rapids impede navigation.

CHAGRES, a seaport town of the United States of Colombia, in the state and on the isthmus of Panama, and at the mouth of the above described river, on the Caribbean sea, 12 m. S. W. of Aspinwall; lat. $9^{\circ} 18' 30''$ N., lon. $79^{\circ} 60'$ W. This place has rapidly fallen into decay since the opening of the Panama railway, the northern terminus of which is at Aspinwall. It is divided by the river into two parts. That on the left bank consists of a number of wooden houses irregularly huddled together, and, having formerly been almost exclusively inhabited by citizens of the United States, is generally denominated the American town; that on the right bank is an agglomeration of miserable huts, in the centre of which is a dilapidated church. The port is very safe and commodious, and defended by a stone fort upon a rock; but it has not more than about two fathoms of water, and the entrance is so narrow that it cannot be successfully approached without a fair wind.

CHAIN SNAKE (*Coronella getula*, Linn.; genus *Ophibolus*, Bd. and Gd.), an American species, first described by Catesby under this name; it is also called thunder snake, and king snake. It has been arranged under different genera, but the above is the name given to it by Dr. Holbrook. The head is small, short, and rounded at the snout; the nostrils are large, and open laterally; the eyes small, and the iris dusky; the neck is very little contracted, and is covered above with small smooth scales; the body is elongated, stout, with large, smooth, six-sided scales above, and large plates below; the tail is quite short, thick, and soon tapers to a horny point. The colors of this handsome snake are singularly arranged; the groundwork of the whole upper surface is a rich shining black, all the plates about the head being marked with one or more white spots;

Chain Snake.

the chin and throat are white, most of the plates being margined with black; on the body are about 22 transverse narrow white bars, embracing two or parts of three scales,

bifurcating on the sides, one branch going to the ring in front, the other to the ring behind, causing a nearly continuous waving white line on the sides from the neck to the vent; alternating with the dorsal bars there are irregular white blotches reaching to the abdomen, which is shining violet black; the tail has four or five transverse rings. The abdominal plates are about 215 in number, and the bifid subcaudal scales from 40 to 50. In a specimen 42 inches long, the head measures a little over an inch, the body 36 inches, and the tail 5 inches; they attain the length of more than 4 feet. Though fond of moist and shady places, it does not take to the water or to trees; it feeds on moles, mice, small birds, and reptiles, and even other snakes. It is found from New York to Florida; its western limit is not positively known.

CHAIX D'EST ANGE, Gustave Louis Adolphe Victor Charles, a French advocate, born in Rheims, April 11, 1800. An able defence of the political conspirators of 1820 and 1821 gained for him early popularity. He afterward distinguished himself in criminal trials, where he was considered as almost without a rival. Elected to the chamber of deputies by his native city in 1831, he took his seat among the moderate members of the opposition, and gave peculiar attention to the questions of copyright and individual liberty. One of the interesting trials in which he was engaged in 1832 was in reference to Victor Hugo's drama, *Le roi s'amuse*, when he was employed by the government to sustain the suppression of the drama, and in which he had the author himself and Odilon Barrot as adversaries. A member of the constituent assembly in 1848, he evinced great zeal in his opposition to the doctrines of the socialists, with a leaning to the Bonapartists. His sympathies were rewarded in 1857 by the place of attorney general to the imperial court of justice, in which capacity he appeared as prosecutor against the Italians implicated in the attempt of Jan. 14, 1858, upon Napoleon III. Soon afterward he was made councillor of state, and became a senator in 1862, and vice president of council Oct. 18, 1863.

CHALCEDON, an ancient town of Asia Minor, on the Bosphorus, opposite Constantinople, and near the modern town of Scutari. It was founded by a colony from Megara about 680 B. C., who were ridiculed as blind by the ancients because they settled here and overlooked the admirable site directly opposite, where Byzantium was founded about 20 years later. For this reason Chalcedon was often called the city of the blind. About 506, in the reign of Darius, it was taken by the Persians, then by the Athenians and Lacedæmonians, and after a period of independence fell under the dominion of the kings of Bithynia. The Romans got possession of it in 74 B. C. Its walls were destroyed by Valens, and it is now but a poor village called Kadi-kei.—In ecclesiastical history Chalcedon is celebrated as the seat of the

fourth œcumenical council, convoked in 451, at the request of the patriarch of Constantinople, Flavian, by the emperor Marcian, to condemn the heresy of Eutyches concerning the two natures of Christ, and to counteract the effect of the unauthorized assembly held at Ephesus in 449, and generally stigmatized as the robber synod. The council met on Oct. 8, and 630 bishops, chiefly from the East, were present. Pope Leo I. presided by his legates. The creeds of Nice and Constantinople were adopted as the rule of faith; and after a prolonged discussion the *latrocinium* of the Ephesian assembly, as well as the doctrines of Eutyches and Dioscorus, in favor of which that synod had pronounced, was condemned. The bishops professed their belief in the existence of two natures in Christ, and declared the Virgin Mary truly the mother of God, directing their decree against both Nestorian and Monophysite doctrines. Fifteen sessions were held, in which 30 disciplinary canons were promulgated, among which was the celebrated decree, opposed by the Roman legates, which made the see of Constantinople equal in privileges and jurisdiction, and next in rank, to that of Rome. It was also ordered that no bishop should take money for ordination, that no ecclesiastic should undertake the administration of the temporal matters of the church or of widows and orphans, forsake the church for any other office, go before a lay tribunal, or hold more than one benefice. Bishops were forbidden to divide their provinces, and were given control over the clergy in monasteries. Deaconesses were forbidden to be appointed under the age of 40. Differences were adjusted between the sees of Antioch and Jerusalem, Nicomedia and Nice; and Theodoret, deposed in consequence of a decree of the assembly of Ephesus, was restored to his bishopric. These decrees were confirmed by Leo, with the exception of the one relating to the see of Constantinople; and throughout the Latin church the council of Chalcedon has always been venerated.

CHALCEDONY (from the city of Chalcedon), one of the numerous varieties of the quartz family, which are distinguished from each other, not by difference of chemical composition, but by their external form, markings, and colors. The peculiarities of chalcedony consist principally in its mammillary, botryoidal, and stalactitic shapes, and its waxy or horny lustre and texture. It is found lining cavities in trap, and also in other rocks, being arranged in concentric layers, precisely as if its particles had been introduced in a gaseous or fluid form. The intermixture of coal with the purely silicious layers suggests that water was present during the production of the mineral incrustation. By the variety of its colors and the high lustre it acquires by polishing, chalcedony is much esteemed as an ornamental stone, though its great hardness renders it very difficult to work. In several of the countries of Asia it is common to find articles of this stone, as cups,

plates, &c., of the most exquisite workmanship, as delicate as the finest chinaware. Specimens of the finest texture and most delicate shades are selected for these, especially such as are more or less white, passing into transparent and brown. At Oberstein, in Germany, chalcidony is worked like agate. (See AGATE.) Some of the finest known specimens of chalcidony were found at the Tresavean copper mine in Cornwall. They occurred in a single pocket or cavity in the mine, and none others were found like them. One of them, described as resembling the anatomized wing of a large bat, displaying its bones and arteries, is preserved in the British museum. The mineral is frequently met with in the United States, and is particularly abundant where metallic veins are worked, but no specimens of extraordinary beauty are found. It also occurs in Nova Scotia and Iceland.

CHALCHIHUITL, the Indian name of a green-colored stone, held in high repute by the ancient Mexicans, and by the Indian tribes now inhabiting the northern and western portions of New Mexico. They possess the art of fashioning it into ornaments, as beads and other trinkets, and occasionally use it in trade, valuing it more highly than gold. It proves, according to the researches of Mr. W. P. Blake, to be turquoise. The locality, at which it has been obtained from remote periods, is in the mountains called Los Cerrillos, 20 m. S. E. from Santa Fé. A quarry of extraordinary extent has been excavated in a granular light-colored porphyry; and around it are a number of smaller excavations. Mr. Blake describes the great pit as appearing, from the top of the cliff, "200 feet in depth, and 300 or more in width." Pine trees more than 100 years old are growing upon the débris in the bottom and about the sides. These excavations were evidently made before the conquest of the country by the Spaniards, though the Indians still continue to visit the locality to search among the débris for more crystals. The earliest historians, as Bernal Diaz, who accompanied Cortes, and others, make mention of chalcihuitls among the presents made by Montezuma, intended especially for the Spanish sovereign. Mr. Blake proposes that the name be retained by mineralogists for this New Mexican variety of turquoise. The Indian pronunciation of it is *chal-che-we-te*. Prof. Pumpelly thinks the *feitsui* and *jade* of the Chinese is the same as the *chalcihuitl* of the ancient Mexicans.

CHALCIDIANs, a family of snake-like lizards, whose scales are rectangular as in ordinary reptiles, and arranged in regular transverse rows; they lead on the one hand to the skinks, and on the other to the long, serpentine lizards, like the glass snake, blindworm, and amphibæna. They have four legs, often very rudimentary, and always small and feeble, with one to four or five toes; the eyes are small, with lids, ears exposed, and tongue short and fleshy. They are found in the warmer parts

of South America, Africa, and the East Indies. By the older naturalists they were regarded as

Brazen Lizard (*Chalcis flavescens*).

snakes, to which they form a natural transition. Their food consists of small insects; they are perfectly harmless.

CHALCIDICE, the ancient name of the peninsula forming the S. E. portion of Macedonia, and terminating in the three smaller peninsulas of Acte, Sithonia, and Pallene, extending into the Ægean sea. Its eastern extremity is Mt. Athos. Generally hilly and rugged, Chalcidice was more celebrated for the ability and energy of its inhabitants than for its productions or natural features. Settled by colonists from Eubœa about the 7th century B. C., the country maintained its independence until after the Peloponnesian war, when it was subdued by the Spartans. Its subsequent history may be found in that of its chief town, Olynthus.

CHALCIDIUS, a Platonic philosopher, supposed to have flourished in the 5th or 6th century. He is described upon the manuscripts of his work as *vir clarissimus*, and these vague words are the only allusions which we have to his life. There remains from him a Latin translation of the first part of the "Timæus" of Plato, with a learned commentary. This work is dedicated to a certain Osius, who has been by some regarded, but without any evidence, as the archbishop Osius who took a leading part in the debates of the council of Nice in 325. Giraldi and Brucker have maintained that Chalcidius was a Christian, Goujet and Mosheim that he was a pagan. The last and best edition of his commentary is that of Fabricius, at the end of the second volume of the works of St. Hippolytus (Hamburg, 1718).

CHALCIS, *Evripo*, *Egripo*, or *Negropont*, the principal town of the island of Eubœa, in Greece, 34 m. N. by W. of Athens; pop. about 6,000. It is the seat of a Greek archbishop, and is said to be the only town of Greece in which any Mohammedan families remain. The city and fortress, which was one of the strongest and most important of ancient Greece, are situated at the narrowest part of the strait of Euripus (*Evripo*) separating the island from Bœotia. The strait here is narrowed by a projecting spur of the mountain of Karababa on the mainland, and the corresponding protrusion of a rocky promontory on the island

side. Over against Chalcis, at about 3 m. distance, is a steep craggy promontory on the mainland, considerably S. of the strait. This is undoubtedly the "rocky Aulis," on which was pitched the camp of Agamemnon when his fleet was wind-bound through the wrath of Diana. This promontory separates two rocky inlets; one is of small size and inconsiderable depth of water; the other is much larger, and is still called Vathy, the modern corruption for *Bathis λιμνη*, the deep harbor, in which lay moored the Grecian fleet. The strait is divided by a rocky islet, which is connected with the mainland by a stone bridge, 70 ft. long, and with Eubœa by a wooden bridge, with draws at each end for the passage of vessels. There are no vestiges of ancient Chalcis, except a few fragments of white marble in the walls of mosques and houses, and the bust of a statue in the wall of a house in the fortress. Many of the better houses are of Venetian construction, and there is a church with a high pointed roof, a square tower, and Gothic windows, which was probably built by the same people. Chalcis was a flourishing town in remote antiquity. It planted colonies in Italy, Sicily, and chiefly in the Macedonian peninsula between the Strymonic and Thermaic gulfs, which from its Eubœan settlements received the name of Chalcidice. On account of its situation it was important in the Grecian wars, and it largely figures in them. The Venetians took it from the Byzantine empire in 1205, and the Turks from them, under the conqueror of Constantinople. Aristotle died here.

CHALCONDYLES, or *Chalcocondyles*. **I. Laonicus** or *Nicolaus*, a Byzantine historian, born in Athens near the end of the 14th century, died about 1464. He was present at the siege of Constantinople, and wrote a history of the Turks and the fall of the Byzantine empire, which is quoted by Gibbon. The best Greek edition was published in 1650, and a French translation by Blaise de Vignères (1557-'84). **II. Demetrius**, a Greek scholar, a relative, some say a son, of the preceding, born in Athens about 1423, died in Milan about 1510. He taught Greek at Perugia, and was afterward appointed professor at Florence, where he remained till 1492, when he removed to Milan. He prepared the first printed editions of Homer (Florence, 1488), of Isocrates (Milan, 1493), and of Suidas (1499); and composed a Greek grammar, *Erotemata* (Milan, 1493).

CHALDEA, properly the name of the S. W. part of ancient Babylonia, bordering on the N. E. confines of Arabia. So it is mentioned by Ptolemy the geographer. Strabo also speaks of a Chaldean tribe living in that region. This district comprised the most fertile plains of Babylonia, made wonderfully productive by the numberless canals constructed by the rulers of that empire for defence, commerce, and irrigation. But commonly the name is applied to Babylonia in general, designating the whole of the province, sometimes even the empire of

that name. The Hebrew term, probably for all these meanings, is Chasdim, or land of the Chasdim (Chaldees). The latter first appear in the Scriptures as the owners of the region which was the abode of the ancestors of Abraham, then as a conquering tribe and nation, and besides as a caste of priests or astrologists. The Ur Chasdim (Ur of the Chaldees) of Abraham was considered by many modern critics to have been a place in Mesopotamia, and identical with the castle of the same name, mentioned by Ammianus as situated between Nisibis and the Tigris. This, as well as the circumstance that Chaldeans are mentioned by Herodotus as soldiers in the Assyrian army of Xerxes, and by Xenophon, in the history of the retreat of the ten thousand, as a free and warlike people in the Carduchian mountains, made it appear probable that the original home of this nation was among, or at least near, the mountains of Armenia, whence they made their incursions, it was supposed at different periods, into the neighboring southern countries, subduing Babylon, and afterward Syria. Gesenius supposed their name to have been originally Card, which was changed into Chasdim and Chald, and preserved in that of the modern Kurds, inhabiting the region of the ancient Carduchi. Their Semitic descent seemed to be proved by the language called after them; so Josephus represents them as descendants of Arphaxad, son of Shem, the latter part of that compound name supporting his opinion. But there remained considerable difficulties in critically establishing the early history of this nation. Nimrod, the mighty hunter, who is mentioned in the book of Genesis as the founder of the empire of Babylonia, which is afterward styled the land of the Chaldees, was a Hamite, and seems to have extended his conquest northward, at least according to an almost generally adopted explanation of the passage which speaks of him. The Greeks name Belus as the founder of the same empire. Nothing is said in the Bible about the nation to which belonged Amraphel, the king of Shinar, that is, Babylonia, who fought a battle in Palestine in the days of Abraham; and a chasm of about 13 centuries separates the first mention of the Chaldeans, in connection with the Ur of the ancestors of the patriarch, from their next re-appearance in the Scriptural history, in the time of Isaiah (except their being mentioned in the book of Job as capturing the camels of the patriarch of Uz); while Babylonia, which appears first at the same time in relation with the history of the Hebrews, is known from the testimony of the classical writers to have existed during this whole period as a highly developed state, by turns conquering and conquered, a product of its advanced industry being also mentioned in the history of Joshua. A natural consequence of these dates would therefore have been the conclusion that Babylonia, having been founded by Nimrod or Belus, be these names identical or not, had reached a

high degree of culture, might, and glory before it was conquered by the warlike tribe who made Babylon the centre of greater conquests, power, and civilization, "the beauty of the Chaldees' excellency," as it is called in Scripture, the *Chaldaicarum gentium caput*, as Pliny calls it. Thus the history of this nation, as masters of Babylonia, would be dated either from the year 747 B. C., the first of the so-called Chaldean era of Nabonassar in the astronomical canon of Ptolemy, who makes him the first of a series of 19 princes of this nation who ruled the great city after the fall of the first Assyrian empire; or from the reign of Nabopolassar, who in alliance with Cyaxares, king of the Medes, broke the yoke and conquered the capital of the Assyrian state, thus founding the independence of Babylonia, and its predominance in western Asia, which his son Nebuchadnezzar so vastly extended. But this conclusion is weakened by the circumstance that Babylon is known to have been already in the most remote periods of history the seat of a system of religious worship and science, which in antiquity was generally attributed to the genius and made the glory of the Chaldeans, whose name both in Biblical and classical antiquity designates not only the nation, but also the peculiar priest caste devoted to the sacred science of astrology; it being also mentioned that Callisthenes, who accompanied Alexander on his expedition to Persia, sent Aristotle a collection of astronomical observations made by the Chaldeans in the temple of Belus, their observatory, during a period of no less than 1,903 years. It is moreover shaken by the contents of the fragments of the Babylonian historian Berosus, which though full of extravagant legends, at least prove a very ancient belief that the Chaldeans were the earliest or among the earliest organizers of Babylonian society. Berosus speaks of an antediluvian dynasty of Chaldean kings, during the early time of which Oannes, an extraordinary being, half man, half fish, speaking with a human voice, came out of the waves of the Erythrean sea to teach the inhabitants of the shore religion and laws, science, art, and industry, retiring every evening into the sea and reappearing every morning. He and his successors became the civilizers of the people of Babylonia. Some critics have seen in this myth of Oannes a confirmation of a relation of Diodorus, according to which a colony from Egypt headed by Belus, the son of Poseidon and Libya, carried the science of their land over the sea to the inhabitants of the Babylonian plains, which served to vindicate the claims of the Egyptians for the priority of their astronomical knowledge over that of their great Asiatic rivals; while others regarded the Chaldeans as the fathers of astronomy, and their country as the focus of this science, whence it spread to India, Egypt, and the West. The third dynasty of the postdiluvian kings of Berosus is also Chaldean. The most plausible way of reconciling the discrepancies

in the testimony of the ancients seemed to the critics of the school of Gesenius, whose dissertation on the Chaldeans in the *Encyclopædie* of Ersch and Gruber was long regarded as the best solution, to be to sum up the history of the Chaldeans as follows: Their first home is either in the mountains of Armenia, or somewhat further N. in those of the Caucasus, or further S. in those of Kurdistan; their Scriptural ancestor being either Arphaxad, son of Shem, or Chesed, son of Nahor, likewise a Shemite. They spread over Mesopotamia and made incursions into Babylonia. A colony of them, soon after the foundation of Babylon, establishes the influence of their priest caste in that state. Like the Brahmans of India, they rule the public worship, and through it the laws and manners of the Babylonians. They develop art, industry, and commerce, but above all the science of astronomy and astrology. They occupy the highest rank in the state, and its governors or viceroys in the period of subjection to Assyria are chosen from their body, of which is also Nabonassar, who heads the series of Ptolemy's 19 Chaldean princes, probably vassals of the Assyrian empire. One of these princes is Merodach-baldan (mentioned also under this name by Berosus, and under that of Mardokempad by Ptolemy), who in the time of Sennacherib sends ambassadors to Hezekiah, king of Judah, probably with the object of forming an alliance against the common oppressor. His successor, Belibus, is carried away as captive by Sennacherib, who makes his own son Esarhaddon (the Asardon of Berosus) viceroy of Babylonia. In the mean time the stock of the Chaldean nation remains in their native mountains, warlike, fierce, and predatory. They appear as plundering invaders in the book of Job, and at a later period as Persian soldiers in the history of Herodotus, and as a warlike mountain tribe in Xenophon's *Anabasis*. Strengthened by new immigrations of this warlike people, Nabopolassar, the Chaldean viceroy of Babylonia, shakes off the yoke of New Assyria, destroys Nineveh with Cyaxares, and thus becomes the founder of the Chaldean empire, now properly so called. Its limits, power, and glory are vastly extended by his son Nebuchadnezzar, who leads his fierce armies and the hosts of his vassals as far as Egypt, or, according to the legend, as far as the pillars of Hercules, peoples his provinces with nations carried into captivity, and adorns his enlarged capital with the treasures of destroyed cities and sanctuaries, with palaces, temples, and magnificent gardens. The Chaldeans are now the nation of Babylonia, though their priests appear also under this name as a caste, or at least as a numerous college, similar to that of the magi of the Medes, devoted to the science of the stars and to the religious practices connected with it. Through Nebuchadnezzar's conquests Babylon is made "the mistress of kingdoms," who says in her heart, "I am, and there is nothing else beside

me." But half a century later "the golden city," enervated by luxury and extravagance, becomes an easy prey to the warlike Medes, "who do not regard silver, nor delight in gold." The "bitter and hasty" nation of the Chaldeans disappears as such, and its name is preserved for some time only in scattered tribes, and its glory in the science of its priests. The determination of the lunar periods, that of the equinoctial and solstitial points, a more precise definition of the solar year, the division of the ecliptic into 12 equal parts, that of the day into hours, the signs, names, and figures of the zodiac, the invention of the dial, are some of the improvements in astronomy attributed to the knowledge of the Chaldeans. With the decline of Babylon their science sinks, and the Chaldeans are afterward known among Greeks and Romans only as astrologers, magicians, and soothsayers, and as such despised, and finally persecuted by some of the emperors.—This scheme of Chaldean history, as far as it relates to the northern origin of the people, is invalidated, though not overthrown, by the results of the archæological researches based on the recent discoveries among the ruins of Babylonia and Assyria. (See CUNEIFORM INSCRIPTIONS.) The main points of these results may be briefly summed up as follows: About the year 2234 B. C. the Cushite inhabitants of southern Babylonia, probably a people identical with the Kaldi mentioned in Assyrian inscriptions of much later date, and of a cognate race with the primitive settlers both of Arabia and of Ethiopia, are supposed to have first risen into importance. Delivered from the yoke of the Medes, whose reign is mentioned by Berosus as that of the first postdiluvian dynasty, they established a native dynasty, founding an empire, whose earliest capitals (the southern or lower tetrapolis) were Hur or Huruk, supposed to be the Scriptural Ur, now Mugheir; Erech, now Warka, or Urka, the great necropolis of Babylonia; Larsa, the Scriptural Ellasar, now Senkereh; and Nipur (perhaps identical with the Scriptural Calneh), the city of Belus, now Niffer. Another tetrapolis, in the northwest, is supposed to have been formed by Babel, Borsippa, Cusha, and Sippara. The city which the oldest inscriptions seem to mark as the Cushite capital is Hur, the southernmost of all, a little below 31° N. lat., near the W. bank of the Euphrates. Its site is presumed to have been originally on the shore of the Persian gulf, which subsequently receded. These Cushites introduced the worship of the heavenly bodies in place of the elemental religion of the magian Medes. In connection with this planetary adoration, whereof the earliest traces appear in the temples of the moon at Mugheir, of the sun at Senkereh, and of Bel and Beltis (or Jupiter and Venus) at Niffer and Warka, the movements of the stars were observed and registered, astronomical tables formed, and a chronological system founded thereupon, such as continued uninterrupted to the days of Cal-

listhenes and Berosus. To this primitive Cushite dynasty, which is probably represented in the Bible by Nimrod, the son of Cush, the two earliest of the monumental kings, Uruk or Urkham and his son Igi, may be assigned. The former, whose seal cylinder is preserved, is described on the monuments as king of Hur and Kingi-Akkad (the Scriptural Accad). The next names on the monuments, in point of antiquity, are Sintishil-Hak and his son Kudur-mabuk or Kudur-mapula. This latter king is designated as the "ravager of the west," and may easily be identified with the Scriptural Chedorlaomer, king of Elam, or Susiana, a country inhabited by a Cushite race; and it is presumed that at this period the Elymæans stood at the head of a confederacy of Cushites, Semites, Aryans, and Turanians, of whom Chedorlaomer, Amraphel, king of Shinar or Babylonia proper, Arioch, king of Ellasar, and Tidal, king of various Turanian "nations," were the respective national chiefs. This combination of races probably gave rise to the name Kiprath-arbat (four tongues), given to the Babylonian people in the inscriptions. Under the Elymæan dynasty, which corresponds to the second postdiluvian Chaldean of Berosus (1976–1518 B. C.), the seat of power was removed northward to the upper tetrapolis, while on the Tigris were laid the foundations of the Semitic realm of Assyria. Several names of the Elymæan dynasty have been recovered from the monuments, among them that of Khammarubi, the builder of temples and constructor of the old royal canal, who gathered the people of "Sumir and Akkad," supposed to have been the chief races of Babylonia, into cities. The following dynasty is designated in Berosus as the Arabian (1518–1273 B. C.). It indicates the overthrow of the Cushite ("Chaldean") ascendancy by a new Semitic conquest or revolution, the origin and character of which are still matters of speculation. The end of this Arab dynasty is followed by the rise of the Assyrian power, with which Babylon long contended for independence and supremacy, until she recovered both under the properly Chaldean dynasty of Nabopolassar. This dynasty is believed to have reestablished the predominance of the southern tribes of Babylonia, while the Semitic languages of Babylonia and Assyria remained the prevailing languages of the empire. (See ASSYRIA, BABYLON, BABYLONIA, CUNEIFORM INSCRIPTIONS, and the authorities referred to under those heads.)

CHALDEE LANGUAGE, the eastern dialect of the Aramaic, of which the Syriac is the western, and which forms the northern branch of the Semitic tongues, the Hebrew, the Arabic, and some other minor dialects forming the southern branch. As the language or one of the languages of Babylonia in the time of its national greatness, whence it was brought by the Jews after their captivity to Palestine, it is also called Babylonian. The Chaldee is known to us only through the writings of Jews, every

other trace of national literature in this language, if there was any such, having disappeared, while of the kindred Assyrian tongue only scanty inscriptions have been preserved. The history of the Babylonian priest Berosus, of which fragments have been saved, was originally written in Greek. Besides a few words in Genesis (xxxi. 47) and Jeremiah (x. 11), we have in the Hebrew canon several chapters of Daniel (from ii. 4 to vii. 28) and Ezra (from iv. 8 to vi. 18, and vii. from 12 to 26) written in this language; and of works of later Jewish writers, the different Chaldaic translations and paraphrases (*Targumim*) of various parts of the Bible, the two Talmuds, and some more modern productions. The apocryphal books of Tobit, Judith, and Maccabees, as well as the history of the Jewish war by Josephus, are also supposed to have been originally written in Chaldaic, this idiom having become by degrees the common language of the Jews after the Babylonish captivity, and particularly from the times of the Maccabees. Of the Targums, that attributed to Onkelos, a strict translation of the Pentateuch, is distinguished by the purity of its idiom, surpassing that of the Biblical fragments; that of Jonathan ben Uziel, a paraphrase of the historic and prophetic books, and the Pseudo-Jonathan and Hierosolymitan paraphrases of the Pentateuch, are less pure and valuable. (See TARGUMS.) Of the Talmuds only the Gemaras or the commentaries are composed in a Chaldaic idiom, which is greatly corrupt, chiefly in that of Jerusalem, and requires a particular study; while the shorter and older Mishnah, or the text, is Hebrew, though with Aramaic features. After the conquest of Babylonia by the Arabs in the year 640, the use of the Chaldee language gradually ceased; and it is now spoken only in a few mostly Christian communities in the mountains of Kurdistan. As a dialect it is distinguished from the Syriac by its avoiding diphthongs and the vowel *o*, for which it generally has *ā*, by the use of *dagesh forte*, as well as by generally accenting the last syllable, and a less defective writing; from the Hebrew, with which it has a common alphabet, by broadness, by substituting labial for hissing sounds, *x* for *ח* and *צ*, *ב* for *ב*, and by comparative poverty in vowels. In forms it is poorer than both the Hebrew and Syriac. To the best grammars of this language belong those of Buxtorf, Michaelis, Harris ("Elements of the Chaldaic Language," London, 1822), Fürst (Leipsic, 1835), Petermann (1841), Winer (Leipsic, 1842), and Bertheau (Göttingen, 1843). The great dictionary of Nathan ben Jehiel of Rome (of the 11th century), entitled *Arukh*, and enriched with additions by Mussaphiah, has been published in a more modern form by Landau (5 vols., Prague, 1819 *et seq.*). Buxtorf's *Lexicon Chaldaicum, Talmudicum et Rabbinicum* (Basel, 1640), is founded upon it. Luzzatto's *Oheb-Ger*, Geiger's *Lehr- und Lesebuch zur Sprache der Mischna* (Breslau, 1845), and J. Levy's *Chal-*

däisches Wörterbuch über die Targumim (Leipsic, 1866-'8) are valuable contributions.

CHALEURS, Bay of (so called from the great heat of the weather when it was first visited by Jacques Cartier, the discoverer of Canada), a wide inlet of the gulf of St. Lawrence, which separates the province of Quebec from that of New Brunswick. It receives the waters of the Restigouche river, which have their source in the mountainous regions of Gaspé, of the Caraquet, the Bass, the Jaquette, the Benjamin, Tête à Gauche, Branche Sud, and Charlot. Here mackerel fishers are attracted in autumn, when that fish arrives in the course of its migrations. It has been a matter of dispute whether this is a bay in the sense of the term intended by the convention of 1818 between England and the United States, and whether the fishermen of the latter country, prior to the treaty of Washington, could be excluded from it. The doubt arose from its extent, 12 to 20 m. in width and 90 in length. Though there are some shallows at the entrance of one or two harbors, the bay affords safe navigation and secure anchorage. In 1760 a French fleet was defeated here by the British.

CHALICE (Lat. *calix*, a cup), the vessel containing the consecrated wine in the sacrament of the eucharist. In honor of its sacred purpose, it has usually been made of as costly a substance as the circumstances of a church permitted, and often embellished with sculptures and precious stones. St. Ambrose relates that in periods of distress the early Christians sold their chalices to aid the poor.

CHALK, an earthy mineral, consisting of carbonate of lime of friable texture, easily rubbed to a white powder. It constitutes rock formations of vast extent, being seen along the shores of the North sea and the English channel, in England and France, towering up in cliffs sometimes 1,000 ft. high, that dazzle the eye with their brilliant whiteness. The rock formation of which chalk is the principal member, and which is called the cretaceous or chalk formation, is the upper group of the secondary series. It is traced across the continent of Europe from the north of Ireland toward the southeast to the Crimea, and from the south of Sweden to beyond Bordeaux, occurring in patches over the greater part of the included area. It gives to the topography an interesting variety of abrupt cliffs upon the coasts and rivers, and of bold hills in the interior, intersected in every direction with valleys of smooth and flowing outline; but the soil it produces is in general too calcareous to be very productive. A remarkable feature in the chalk formation in some localities is the occurrence of layers of flint nodules in the rock, horizontally arranged, and not in contact with each other, and of all shapes and sizes, varying from an inch to a yard in circumference. The flints frequently appear to be concretions of silicious matter around organic substances, as parts of

shells, sponges, &c., into the most minute pores of which the silica has penetrated, beautifully preserving their peculiar forms. The chalk itself is in great part composed of finely comminuted shells and corals, and it is now generally understood to have been derived from the same sources as the fine white calcareous mud which fills the bottoms of coral lagoons, and the interstices of its structures. This proves to be entirely of animal origin, in part finely ground shells and corals, and partly the excrement of shell fish, and of certain gregarious fishes, which in the coral regions of the Pacific were seen by Darwin through the clear waters, browsing quietly in great numbers upon living corals, like grazing herds of graminivorous quadrupeds. In the coral reefs of the south seas Prof. Dana found portions of these as compact and solid as any secondary limestone, and parts of the still growing structures not to be distinguished from portions of the chalk rocks of the cretaceous formation. The fossils of this geological group are all of oceanic families, but of extinct species. Several species found in New Jersey are identical with those of the same formation in Europe; but the chalk is absent, though the other strata of limestone and greensand are recognized as those which elsewhere accompany it.—Chalk is employed for a variety of purposes. It is easily converted into lime, in which state it forms a valuable fertilizer as well as cement. It is used as a marking material, and also for polishing metals and glass. When finely ground, and purified by washing and separating its harder particles, it is sold by the name of whiting, or Spanish white. The flints found in the formation were once much used in England in the manufacture of glass.—In medicine, chalk, when thoroughly purified, is used, under the name of prepared chalk, as an absorbent in diarrhoea; it is also an antacid, and is used to furnish carbonic acid gas; it is also a dentifrice. Chalk mixture is the form in which prepared chalk is commonly administered medicinally. When diarrhoea depends upon irritation or inflammation of the mucous membrane of the bowels, it should not be employed, for it is then more likely to increase than allay the disturbance. It may often be advantageously combined with opium or astringents, or both.—French chalk is a pure variety of steatite or talc, used by tailors for marking cloth, and also mixed with cosmetics to give them body. Black chalk is a variety of bituminous shale, made use of by artists for drawing. Red chalk, or redde, is an argillaceous red oxide of iron.

CHALKLEY, Thomas, a preacher of the society of Friends or Quakers, born in London, March 3, 1675, died in the island of Tortola, West Indies, Sept. 4, 1741. At the age of 20 he was pressed on board a man-of-war, but after a day's detention was discharged on account of his scruples about bearing arms. He engaged in trade for a while, and having made a little money became

an itinerant preacher. He went to America in 1698, landing in Maryland and travelling for a year in Virginia and New England, after which he returned home and married. He then decided to remove permanently to America, made his home in Philadelphia, and spent the rest of his life mainly in travelling and preaching in the English colonies. In 1707 he visited Europe, and after travelling through the British islands made an excursion to Holland and Germany. He went several times to the West Indies, and was engaged in the work of his itinerant ministry at Tortola when he died of fever after a few days' illness. He left an interesting journal of his "Life, Labors, Travels," &c., which was published with a collection of his writings at Philadelphia in 1747, and was reprinted in one volume in New York in 1808. By a bequest in his will he founded the library of the four monthly meetings of Friends at Philadelphia.

CHALLENGE. This word, which is now, except in a legal sense, used chiefly to imply a provocatory summons to mortal combat, seems originally to have conveyed within itself the idea of an appeal, of an exception taken, or a claim asserted, and a disinclination to submit to some decision or arbitration, rendered or about to be rendered, and removal of the subject matter of dispute to some other court or tribunal. Thus, in ancient times, the duello was never the mode of settlement of an angry personal dispute; but it was the trial of a solemn cause before the actual court and in the presence of God. The challenger took exception to the truth of the allegation made against him by his adversary or opponent, and removed the adjudication of the cause, by appeal of challenge, from the human court of law, before which it was pending, to the divine court of equity, which was believed directly to interfere in the event of wagers by battle, and to give the strong arm and the sharp sword to the righteous party. In the same sense, when a jury is challenged, whether by the array or by the poll, exception is taken to the fairness of the impanelling of the whole jury, or to the partiality of the individual juror; and, having taken exception, the person accused by his challenge removes the adjudication of his cause from that entire jury, or from that individual as part of it, to some other, by whom he believes he can have a fair trial, which he denies that he can as it is at present constituted. Challenges to jurors are either to the array, which is to the whole panel, and founded upon some error or partiality on the part of the officer summoning them, or to the polls or individual jurors separately. The latter may be either peremptory or for cause. A certain number of peremptory challenges is allowed in criminal cases, for which no reason need be assigned; but for others legal cause must be given, the sufficiency of which will be determined by the court, or may be referred to triers, if depending upon

disputed matters of fact. The want of statutory qualification, defect of age or mental capacity, bias or partiality for or against a party, a definite opinion formed or expressed upon the case, and relationship by blood or affinity to a party, are causes of challenge; and in capital cases conscientious scruples against the death penalty.—A challenge as a preliminary to a duel is forbidden by the laws of most of the United States, and in the American army by the articles of war. Any officer or soldier sending a challenge to another officer or soldier, or accepting a challenge if sent, incurs the penalty, if a commissioned officer, of being cashiered; if a non-commissioned officer or soldier, of suffering corporal punishment. Any officer who knowingly or willingly suffers any person whatsoever to go forth to fight a duel, is punishable as a challenger, and seconds are not distinguished from principals. The punishment is at the discretion of the court martial, of which if any member is challenged by a prisoner, that member withdraws, and the court is closed to determine upon the relevancy or validity of the challenge. If the challenge is disallowed, the member resumes his seat.—Challenge is also a hunting term, used of hounds or beagles, when, at first finding the scent of their game, they presently open cry; the huntsmen then say they challenge.—Challenges are also used at the polls to prevent illegal voting. Any bystander can challenge a vote and demand that the person offering it be put upon oath. But this duty is usually assigned to persons selected by each party to attend the polls and watch the voters.

CHALLONER, Richard, an English bishop and historian, born in the diocese of Chichester, Sept. 29, 1691, died in London, Jan. 12, 1781. Having become in his youth a Roman Catholic, he was sent by Dr. Gother to the English college at Douai in 1704, of which institution he was vice president from 1720 to 1730. He then returned to England, and served as a missionary priest till Jan. 29, 1741, when he was consecrated bishop of Debra and coadjutor to Bishop Petre, whom he succeeded as vicar apostolic of the London district in 1758. The penal laws made his ministry one of danger, for he was actually indicted under them; but he discharged his duties with unwavering zeal, and organized educational establishments for both sexes. His pen was never idle; his works covered a wide range, and they contributed more than those of any other writer to form the language of religious thought among English-speaking Catholics. His edition of the Bible (5 vols. 12mo, 1750) superseded the old Douai edition, and, though constantly modified, is the Bible still in use among Roman Catholics. It was strictly reprinted for the first time at New York in 1870, only typographical errors being corrected. His "Think Well On't," "Grounds of the Catholic Doctrine," "History of the Protestant Religion," "Catholic Christian Instructed" (in the preface to which he

answered Conyers Middleton's "Letter from Rome"), "Meditations," "Lives of the Fathers of the Desert," "Garden of the Soul, a Manual of Prayers," and his translations of "The Following of Christ" and "The Introduction to a Devout Life," have been reprinted frequently in England, Ireland, and America. His "Memoirs of the Missionary Priests and other Persons of both sexes who suffered Death in England on account of their Religion" has been several times reprinted. Among his other works were "Britannia Sancta" (2 vols., 4to), "Unerring Authority of the Catholic Church," "British Martyrology," and a "Caveat against the Methodists." There is a life of him by Barnard (London, 1784), and a short one by Bishop Milner.

CHALMERS, Alexander, a British author, born at Aberdeen, Scotland, March 29, 1759, died in London, Dec. 10, 1834. He was the son of a printer, received a classical education, and after his arrival in London, about 1777, he wrote for the press and edited many works and several periodical publications. His fame rests on the "General Biographical Dictionary" (32 vols., 1812-'17). He also prepared annotated editions of the British essayists, of Shakespeare, and of the English poets from Chaucer to Cowper. In 1820 he published an abridgment of Johnson's English dictionary by Todd; the 9th edition of Boswell's Johnson in 1822; and a new edition of Shakespeare and one of Johnson's works in 1823. Among his other editions were the complete writings of Fielding, Bolingbroke, and Gibbon, besides a vast number of individual biographies. At different periods he was editor of the London "Morning Herald," associate editor of the "Morning Chronicle," and a frequent contributor, under the signature of "Senex," to the "St. James's Chronicle," as well as to the critical reviews.

CHALMERS, George, a British historian, born at Fochabers, Scotland, in 1742, died in London in 1825. He studied law at Aberdeen, accompanied an uncle to the North American colonies, and settled at Baltimore. At the commencement of the revolution he returned to England. He wrote "An Estimate of the Comparative Strength of Great Britain" (1782; new and enlarged ed., 2 vols., 1810), and "Political Annals of the United Colonies" (1780; new and enlarged ed., 2 vols., Boston, 1845); the lives of Defoe, Thomas Paine, and others; and "Life of Sir David Lyndsay, and a Glossary of his Poetical Works" (3 vols., 1806). A second edition of his valuable "Life of Mary Queen of Scots, from State Papers," was published in 3 vols. in 1822. His principal work is "Caledonia," a comprehensive historical account of Scotland from the earliest periods (3 vols., 1807-'24). This was to have extended to six volumes, and the fourth volume was left in MS.

CHALMERS, Thomas, D. D., a Scottish clergyman and author, born at Anstruther, Fifeshire, March 17, 1780, died at Morningside, near

Edinburgh, May 31, 1847. His father was a shipowner and general merchant. Destined for the church, he was sent at the age of 12 to the university of St. Andrews, where his favorite studies were mathematics, ethics, and political economy. In his 19th year he received a preacher's license in the Scottish church, but declined to assume a pastorate, and spent the two subsequent winters in Edinburgh, where he was employed in teaching while pursuing a wide range of study under Dugald Stewart, Robison, Playfair, and other professors. From assistant minister in a small parish he became in 1803 minister at Kilmany, Fifeshire, at the same time lecturing upon mathematics and chemistry at St. Andrews and gaining reputation as a savant. In 1804 and 1805 he applied unsuccessfully for professorships of natural philosophy at St. Andrews and of mathematics at Edinburgh. His first effort in authorship was a pamphlet to prove that the vigorous prosecution of science was not incompatible with ministerial duties and habits. On Napoleon's menace of invading England, Chalmers joined a corps of volunteers both as chaplain and lieutenant. In 1808, upon the alarm created by Napoleon's decrees against British commerce, he published his "Inquiry into the Extent and Stability of National Resources," to show that the apprehensions were groundless. He had already become a contributor to the "Edinburgh Encyclopædia," and the article on Christianity was assigned to him. While preparing this article, amid many domestic bereavements and a long and severe illness in 1809, which brought him near to the grave, he experienced a great spiritual change, and upon his recovery displayed a fervor in the pulpit and in his household visitations which was new to his parishioners. Cherishing scientific and literary studies with the same ardor as before, and contributing to the "Christian Instructor" and the "Eclectic Review," yet all his thoughts were tempered by a deep sense of religion. Having before belonged to the "moderate" party in the Scottish church, he now ranked with the "evangelical" party, which was in the minority, and his pulpit eloquence attracted listeners from great distances, and made him famous through the south of Scotland. In 1812 he married, and his wife, who survived him, bore him six children. In 1813 his article on Christianity appeared in the "Encyclopædia," and was immediately republished in a separate volume, with additions, under the title of "Evidences of Christianity." During the next two years he was busily engaged in organizing Bible and missionary societies, with a view to providing for the spiritual and general improvement of all his parishioners. He wrote about this time for the periodical press on missions and on Cuvier's theory of the earth. In 1815 he became minister of Tron parish, Glasgow, and during the eight years of his residence in that city he enjoyed unrivalled renown as a pulpit orator. The "Astronomical

Discourses," a series of weekly lectures on the connection between the discoveries of astronomy and the Christian revelations, were published in 1817, and within a year nearly 20,000 copies of them were sold. His fame had meantime extended from Scotland to London, where he preached first in this year. In a time of high political excitement all parties thronged to hear him. Canning and Wilberforce went together. The latter wrote in his diary: "Canning was at first disappointed by the preacher's peculiar manners, but at the end of the sermon he said to Wilberforce, 'The tartan beats us; we have no preaching like that in England.'" The article on "Pauperism" contributed to the "Edinburgh Review" immediately after his return to Scotland, and the tracts on the "Christian and Civic Economy of Large Towns," which soon followed, indicate what was then the direction of his efforts. It was his aim by a thorough organization to revive the old parochial system of Scotland, and, by dividing the community into small manageable masses, to bring every member of it directly under educational and ecclesiastical influences. To apply his scheme, he exchanged the Tron parish for the neighboring one of St. John's (1819), in which out of 2,000 families there were more than 800 unconnected with any Christian church, and a countless number of untaught children. The entire management of the poor in that parish was committed into his hands as an experiment, and by strict parochial oversight the entire pauper expenditure was reduced in four years from £1,400 to £280 per annum. Every street and lane was visited periodically by his agents and teachers. In this great labor Edward Irving, then in the beginning of his career, was his assistant. Dr. Chalmers had never ceased to aspire to a professorship in one of the Scottish universities, and in January, 1823, he accepted a call to the chair of moral philosophy in the university of St. Andrews. In this office he remained five years, and its literary results were his "Lectures on Moral Philosophy," and his work on "Political Economy in connection with the Moral Aspects of Society." He had given a new intellectual impulse to the studies in his department, when in 1828 he was transferred from St. Andrews to the chair of divinity in the university of Edinburgh, where he remained during the next 15 years. In 1830 he was appointed royal chaplain. He carried his eloquence and enthusiasm into the class room, which was filled not with students alone, but with clergymen of various denominations and eminent literary and scientific men. In 1833 he published his Bridgewater treatise on the "Adaptation of External Nature to the Moral and Intellectual Constitution of Man;" in 1838 he delivered a course of lectures in London in defence of church establishments; and after a short visit to France he travelled through Scotland, to lecture and collect funds in behalf of the move-

ment which he had initiated of so increasing the number of churches in the country, that no locality should be without the discipline of religion. In 1834 he was elected fellow of the royal society of Edinburgh, and in 1835 the degree of D. C. L. was conferred upon him by the university of Oxford. He had become the acknowledged leader of the evangelical party in the church of Scotland, and in 1832, when that party attained the majority, he had received the highest honor which that church can bestow, by being appointed moderator of the general assembly. It was mainly by his influence that this assembly passed in 1834 the famous veto act, which, being declared illegal, led to violent controversies and disturbances, which culminated in 1843 in a considerable secession from the established church, and in the foundation of the Free Church of Scotland, with Dr. Chalmers as the first moderator. (See FREE CHURCH OF SCOTLAND.) He immediately resigned his chair in the university, and devoted the remaining four years of his life with his characteristic skill and energy to the organization and consolidation of the new church. At the same time he was the principal and professor of divinity in the newly established college connected with the Free Church, and wrote for the "North British Review," which periodical was founded under his auspices. On his return from a journey to London which he had undertaken to enlist the sympathies of leading statesmen in behalf of his views on national education, he retired to rest in his usual health, but was found next morning dead in bed, without a single trace of suffering on his countenance.—The following are his collected writings in the order of their publication (25 vols. 12mo, Edinburgh): vols. i., ii., "Natural Theology;" iii., iv., "Christian Evidences;" v., "Moral Philosophy;" vi., "Commercial Discourses;" vii., "Astronomical Discourses;" viii., ix., x., "Congregational Sermons;" xi., "Sermons on Public Occasions;" xii., "Tracts and Essays;" xiii., "Introductory Essays to Select Authors;" xiv., xv., xvi., "Polity of Nations;" xvii., "Church Establishments;" xviii., "Church Extension;" xix., xx., "Political Economy;" xxi., "Parochial System;" xxii.—xv., "Lectures on the Romans." His posthumous works, edited by the Rev. Dr. Hanna (9 vols. 12mo, Edinburgh and New York, 1847-'9), are: "Daily Scripture Readings" (3 vols.); "Sabbath Scripture Readings" (2 vols.); "Sermons," illustrative of different stages in his ministry (1 vol.); "Institutes of Theology," a reproduction of his theological lectures (2 vols.); "Preelections on Butler's Analogy" (1 vol.). His "Christian Evidences" have passed through many editions, and have been twice translated into German (1834 and 1841), and into French (1819 and 1836). A German translation of his "Civil and Christian Economy of Large Towns," by O. von Gerlach, appeared in Berlin in 1847; and a French selection of his sermons by E.

Diodati (1825) was followed by *Révélation en harmonie avec l'astronomie moderne*, a version of his "Astronomical Discourses" (1826). His writings on political economy were also highly appreciated in France and Germany, and led the French institute to elect him in 1834 as corresponding member. The principles pervading his "Political Economy in connection with the Moral State and Prospects of Society" (Glasgow, 1832), being chiefly those of Malthus, have incurred the censure of McCulloch, who likewise disapproved of Chalmers's opposition to poor laws and other compulsory provisions for the destitute. His literary and scientific activity, prodigious as it was, is yet regarded as on the whole subordinate in importance to his social and ecclesiastical reforms and to the influence of his personal magnetism and genius. Yet his appearance and manner were far from prepossessing; his face when in repose was singularly unanimated; his gestures were rather awkward; his voice was neither strong nor musical; his style was often inflated, and disfigured by a somewhat eccentric phraseology. But his earnest piety and fervid imagination, which imparted a poetic charm to his discourses and writings, more than redeemed all his oddities. His broad Scotch accent, his unaffected manner, and his strong sympathies with the habits and feelings of the Scotch masses made him as popular with the people as his genius made him famous among scholars.—See "Memoirs of the Life and Writings of Dr. Chalmers," by his son-in-law, the Rev. William Hanna, LL. D. (4 vols. 8vo, Edinburgh and New York, 1849-'52); "Correspondence," edited by the same (1853); "Memorials of his Time," by Henry Cockburn (London, 1856), especially interesting as an authority on Dr. Chalmers's peculiarities of manner; "Memoir of the Christian Labors, Pastoral and Philanthropic, of Thomas Chalmers," by Francis Wayland (Boston, 1864); "Thomas Chalmers, D. D., a Biographical Sketch," by Dean Ramsay (1867); and "Thomas Chalmers, a Biographical Study," by J. Dodds (New York, 1870). In 1869 preliminary steps were taken for the erection at Edinburgh of a monument to Chalmers.

CHÂLON-SUR-SAÔNE (anc. *Cabillonum* or *Ca-ballinum*), a walled city of France, in the department of Saône-et-Loire, 33 m. N. of Mâcon, and 185 m. S. E. of Paris; pop. in 1866, 19,982. It is situated on the Saône, in one of the most fertile regions of Burgundy. It has four suburbs, fine promenades, a splendid quay, and a stone bridge of five arches over the Saône. The principal church is that of St. Vincent, formerly a cathedral. The canal du Centre here unites the Saône with the Loire; and this, with the railway from Paris to Lyons, gives to the town an important transit business. There is also an active trade in wine, vinegar, mustard, grain, and various local manufactures.—It was an important city of ancient Gaul and of the Roman empire, and figures in Cæsar's Commentaries. Converted to Christianity by St. Marcel

and St. Valerius in the 2d century, Châlon early became the seat of a bishop, who afterward assumed the title of count of Châlon and baron of Salle. The see was united with that of Autun in 1801. Many important ecclesiastical councils were held here from the 5th to the 12th century. Attila destroyed the town. Having passed from the Burgundians to the Franks, it became in the 6th century the capital of the first Frankish kings of Burgundy. In the 10th century it formed with its territory the Burgundian county of Chalonnais, which reverted to the duchy of Burgundy in 1237, and under Louis XI. was united with the latter to the French crown. Abélard died in the abbey of St. Marcel near this town, the only vestige remaining of which is the church.

CHÂLONS-SUR-MARNE (anc. *Catalauni*), a walled town of Champagne, France, capital of the department of Marne, 90 m. E. of Paris; pop. in 1866, 17,692. It is situated on the right bank of the Marne, on the canal uniting that river with the Rhine. The streets are narrow, but well built, and the promenade du Jard is planted with 2,000 elm trees. The cathedral has been often restored, before and after the fire of 1668. The finest church, that of Notre Dame, suffered greatly during the revolution. The former palace of the count of Artois, containing valuable archives, is used as the prefecture. There are a fine town hall, a public library of 30,000 volumes, a departmental college, a school for art and industry, a cabinet of natural history, a botanical garden, and agricultural, scientific, and artistic societies. Leather, woollen, and cotton goods, hosiery, and other articles are manufactured, and there is an active trade in grain, flour, hemp, wool, and other commodities; but the chief trade consists in champagne wine, of which the average annual export is about 1,000,000 bottles. The Jacqueson cellars, in the suburb of that name, can hold over 3,000,000 bottles; the galleries, excavated in the chalk rock, being 6 m. long. The beautiful Gothic miniature cathedral of Notre Dame de l'Épine, on the Vesle, 6 m. from Châlons, has been restored since 1860.—The city belonged to the territory of the Catalauni, in Gallia Belgica. Tetricus was defeated here by Aurelian in A. D. 274; the Alemanni by Jovinus in 366; and the great battle between the combined armies of Aëtius and Theodoric and the Huns under Attila was fought in 451 near this city, on the Campi Catalaunici, which lie on the branch railway from Châlons to Rheims. (See *AËRRUS*.) Attila, who was defeated, is said to have been induced by the eloquent pleading of the bishop St. Alpinus to spare the city. The bishops of Châlons formerly wielded great power. The city was captured by Count Herbert of Vermandois in the 7th, and by Rudolph of Burgundy and Robert of Vermandois in the 10th century. An ecclesiastical council was held here in 1129, when the bishop of Verdun was deposed by St. Ber-

nard, who afterward preached a crusade here. Henry IV. removed the parliament from Paris to Châlons in 1589, and in 1591-'2 citizens burnt the bulls by which Gregory XIV. and

The Church of Notre Dame.

Clement VIII. excommunicated that king. Châlons was occupied by the Prussians in 1814, and taken by the Russians in July, 1815. In 1856 Napoleon III. established the military camp of Châlons, about 11 m. N. E. of the town, on the railway to Rheims and Verdun. Periodical exercises were held here from 1857 to 1870; and on the outbreak of the Franco-German war, Canrobert was stationed here as commander of the 6th army corps. The imperial headquarters, comprising 25 buildings, were about half a mile from the camp. After the first defeats of the French and the transfer of Canrobert's troops to Metz, the débris of the armies of MacMahon and De Failly were reorganized here by the former, and reinforced. They evacuated the camp and partly destroyed it in the night of Aug. 21-22; and on the following day the city of Châlons was occupied by the Germans, who used the place as a rallying point between their army before Paris and their forces in the interior of France.

CHALOTAIS, La, Louis René de Caradec de, a French statesman and author, born at Rennes, March 6, 1701, died there, July 12, 1785. He was procureur général of the parliament of Brittany, and became known by his reports to that body against the Jesuits, the authorship of which was ascribed to D'Alembert. A new edition of these *Comptes rendus des constitutions des Jésuites* (2 vols., Paris, 1761-'2) was published in 1826. According to Grimm, his reports led to the abolition of the society of Jesus in France; and he as well as Voltaire also awarded the highest praise to La Chalotais's *Essai d'éducation nationale* (1763; new

eds., Paris, 1825 and 1826). Having become engaged in a dispute with the duke d'Aiguillon, governor of Brittany, that functionary accused him of seditious proceedings, and had him arrested (Nov. 11, 1765), with four of his colleagues and his son Caradec de la Chalotais, who was also a procureur général in the Rennes parliament. He was detained in the castle of St. Malo, and wrote there, Jan. 15, 1766, with his toothpick in the absence of pens, his first memoir in vindication of his course. Voltaire averred that this toothpick had achieved immortality. He wrote several similar memoirs, and the proceedings against him, being regarded as an infringement of the rights of parliament, gave rise to protracted controversies. The parliament eventually instituted proceedings against the duke d'Aiguillon, who was proved to have procured evidence against La Chalotais by false witnesses, and whose papers were seized and publicly burned by order of the parliament, though he brought countercharges against his adversaries, and the crown seemed to take up his case as against parliament. After much agitation the matter came before the parliament of Paris in 1770. Louis XV. at first presided, but soon withdrew on the pretext that his royal authority was impaired by the pretensions of the parliament. This body, however, insisted on its prerogatives, and continued its investigations; but La Chalotais did not recover his liberty till 1775, after the king's death, when he resumed his previous position at the parliament of Rennes. *Le procès de M. de la Chalotais* was published in 1767 (3 vols. 4to).

CHALYBÄUS, Heinrich Moritz, a German philosopher, born at Pfaffroda, Saxony, July 3, 1796, died in Dresden, Sept. 22, 1862. He studied philology and philosophy, received the degree of D. D. from the Leipzig university in 1820, became teacher and professor in various places, and was from 1839 to 1862 professor of philosophy at the university of Kiel, with the exception of a brief period subsequent to the Schleswig-Holstein war. This appointment was mainly due to the reputation of his *Historische Entwicklung der speculativen Philosophie von Kant bis Hegel* (Dresden, 1836; 5th ed., 1860; English translation by Tulk, London, 1854). He wrote several other works, the most important of which was *System der speculativen Ethik* (2 vols., Leipzig, 1850), in which he defines ethics as the complete embodiment of absolute truth. His *Philosophie und Christenthum* (Kiel, 1853) and *Fundamental-Philosophie* (1861) were his latest publications.

CHALYBEATE (from *Chalybes*, a Scythian people, S. and S. E. of the Black sea, who worked in iron, whence Gr. *χάλυψ*, steel), a name now applied to waters and medicines which contain iron. It generally exists in them in the state of the carbonate of the protoxide, which is soluble so long as an excess of carbonic acid gas is present; as this is given off, the protoxide absorbs oxygen, and is converted

into an insoluble hydrated sesquioxide, which falls down as a yellow ochreous powder. Chalybeate waters possess a styptic taste, and give the characteristic reactions indicative of the presence of iron by the addition of nutgalls and of ferrocyanuret of potassium. In this country springs that might claim this name are very common. The most important of them are those of Bedford and Brandywine in Pennsylvania. Arsenic and copper are found in Europe in the sediment of chalybeate springs. They appear to do no harm, on account of the antidotal properties of the oxide of iron.

CHAM, the assumed name of AMÉDÉE NOÉ, a French caricaturist, born in Paris, Jan. 26, 1819. He is a son of the count de Noé, studied painting, and acquired celebrity by his caricatures in the *Charivari* and other illustrated papers, many of which have been collected in separate publications. He is also the joint or sole author of librettos and vaudevilles. His cartoons, many of which have a political aspect, are notable for their sharp point and free, spirited execution.

CHAMA (Gr. *χάω*, to gape), a genus of lamellibranchiate bivalves of the family *chamidae*, which includes also the genera *monopleura* and *dicerias*, all distinguished by inequivalve shells, one of which has two teeth and the other one; the foot is small, as also the corresponding pedal orifice. More than 50 species are described, inhabiting tropical seas, especially among coral reefs, as deep as 50 fathoms; nearly as many fossil species have been found, from the greensand forward, both in America and Europe. Having two abductor muscles, they belong to the dimyary group, and, like the kindred families of this group, have short siphons and are marked by a simple pallial line. By Linnæus, Cuvier, and De Blainville, the genus was made of great importance, including many shells now transferred to other families. The giant clam, *tridacna gigas*, was one of these. (See CLAM.)

CHAMBERLAIN (Fr. *chambellan*; Lat. *camerarius*), an officer attached to royal courts, and to establishments of the great. The word means simply a person having care of apartments, and in its early acceptance was so employed. At present the duties of the office are nominal, or limited to such easy service as attending on the person of princes. Formerly the office had so many perquisites that it was sought by individuals of noble families, and finally became one of the grand offices of the crown. The title of grand or great was added to distinguish the chamberlains of sovereigns from those of lesser dignitaries. The earliest officer of this rank in France was appointed by Louis VII.; 39 chamberlains followed in succession till the time of Louis XIV., when the dignity was suffered to lapse. Napoleon I. revived the office. In Anglo-Saxon times the chamberlain was called the *camerarius*, and had charge of the king's treasure. Under the Norman kings the office of lord great chamber-

lain was hereditary, and by the statute of precedence, 31 Henry VIII., his place was next that of the lord privy seal, where it also is under the most recent statute on that subject. The duties which devolve upon the office now are the dressing and attending on the sovereign at coronation; the care of the ancient palace at Westminster; the furnishing of the houses of parliament and Westminster hall for great occasions; and during the sitting of parliament he has charge of the house of lords. In consequence of descent to females, the office is now held jointly by the families of Cholmondeley and Willoughby d'Eresby, whose representatives discharge the duties alternately in each succeeding reign.—The office of lord chamberlain in Great Britain is distinct from this, is filled by appointment, and changes with the administration. He is the head of the royal household, and has control over all the officers and servants except those of the bedchamber, and the royal chaplains, physicians, surgeons, &c.; the royal tradesmen are also appointed by him. Theatres in towns in which a royal palace is situated are licensed by him, and he is also the licenser of plays, and has the regulation of the companies of actors at the royal theatres. He also issues the royal invitations to balls, parties, &c.; and applications for presentations at court must be made to him. A vice chamberlain performs his duties in his absence. There was also a chamberlain and vice chamberlain in the exchequer court of the county palatine of Chester; and many of the municipal corporations of England have an officer by this title, whose duties in general are to take charge of the property and finances of the corporation. The chamberlain of the city of New York is charged with similar functions. The chamberlain of London has also duties of a judicial nature, pertaining to masters and apprentices.

CHAMBERLAYNE. **I. Edward**, an English author, born at Odington, Gloucestershire, in 1616, died at Chelsea in 1703. Educated at Oxford, he travelled abroad during the civil wars. In 1679 he was appointed tutor to Henry, duke of Grafton, a natural son of Charles II., and afterward to Prince George of Denmark, the husband of Queen Anne. He is best known by his "*Angliæ Notitia*, or the Present State of England" (London, 1667), to which Macaulay frequently refers, and which passed through many editions. An inscription on his grave in Chelsea states that six of his works were buried along with him. **II. John**, son of the preceding, died in 1723. He continued his father's work under the title of "*Magnæ Britannicæ Notitia*, &c.", publishing several new editions. With all its defects, this was the only statistical authority of his day. He was a graduate of Oxford, wrote several original works, and translated the "Religious Philosopher" from the Dutch of Nieuwentyt (3 vols., 1718).

CHAMBERS. **I.** An E. county of Alabama, bordering on Georgia; former area, 775 sq. m.,

which has been diminished by taking a portion to form Lee county; pop. in 1870, 17,562, of whom 8,588 were colored. It is partly bounded on the E. by the Chattahoochee river, and intersected by the Tallapoosa. The surface is hilly, and most of the land productive. The Montgomery and West Point railroad passes through the S. E. part. The chief productions in 1870 were 39,532 bushels of wheat, 205,099 of Indian corn, 35,921 of oats, 24,734 of sweet potatoes, and 7,868 bales of cotton. There were 1,382 horses, 1,457 mules and asses, 2,895 milch cows, 4,814 other cattle, 3,861 sheep, and 9,725 swine. Capital, Lafayette. **II.** A S. E. county of Texas, bounded S. by the gulf of Mexico, having Cedar bayou for a part of its W. boundary, and indented on the W. and S. W. by East and Galveston bays; area, 900 sq. m.; pop. in 1870, 1,503, of whom 452 were colored. It is intersected by Trinity river, the banks of which are timbered, but the greater portion of the county consists of prairie lands. The chief productions in 1870 were 23,759 bushels of Indian corn, 15,200 of sweet potatoes, and 105 bales of cotton. There were 1,444 horses, 1,205 milch cows, 24,572 other cattle, 1,700 sheep, and 2,352 swine. Capital, Wallisville.

CHAMBERS, Ephraim, an English cyclopædist, born at Kendal, Westmoreland, in the latter half of the 17th century, died in London, May 15, 1740. He was the son of a Presbyterian freeholder, and while apprentice to the mechanic Senex, who encouraged his scholarly tastes, he began to prepare a cyclopædia, which after many years of arduous labors, in his chambers at Gray's Inn, was published by subscription (2 vols., 1728; 2d enlarged ed., 1738; 5th ed., 1746). Subsequently this work was enlarged by Mr. Scott and Dr. Hill, and eventually served as a basis for Rees's Cyclopædia (4 vols., 1781-'6; new and enlarged, ed., 45 vols., 1803-'19). Chambers contributed to the "Literary Magazine," and prepared with John Martyn an abridged translation of the philosophical history and memoirs of the French academy of sciences (5 vols., 1742). He was elected fellow of the royal society, and was buried in Westminster abbey.

CHAMBERS, George, an English artist, born at Whitby, Yorkshire, late in the 18th century, died in London, Oct. 28, 1840. The son of a poor seaman, he became cabin boy on a sailing vessel; but his sketches of shipping induced his master to cancel his indentures. After various struggles, during which he perfected his knowledge of art, he was employed by Thomas Horner for seven years in preparing the panorama of London for the Colosseum. Admiral Lord Mark Kerr became his patron, and he painted the "Opening of New London Bridge" for William IV., and a view of "Greenwich Hospital" for Queen Adelaide. His appointment as marine painter to their majesties had opened to him a way to fame and fortune, when his health broke down. His best works

are his pictures of naval battles, three of which are in Greenwich hospital.

CHAMBERS, Sir William, an English architect, of Scottish descent, born in Stockholm about 1726, died in London, March 8, 1796. He was educated at Ripon, Yorkshire, went as supercargo to the East Indies, spent some time in China, and brought back many drawings of Chinese buildings and costume, which were published in 1757. He then devoted himself to architecture, and on returning from France and Italy he settled in London in 1744, and was appointed drawing master to the prince of Wales, afterward George III. He laid out the royal gardens at Kew in the Chinese style, and built the villa of the earl of Besborough at Roehampton, and other fine mansions, in the Italian style. His masterpiece was Somerset house in London, which he rebuilt in 1775. He published in 1759 a "Treatise on Civil Architecture," which has been several times reprinted; and in 1772 a "Dissertation on Oriental Gardening."

CHAMBERS, William and Robert, Scottish authors and publishers, born at Peebles, William in 1800, and Robert in 1802; the latter died March 17, 1871. Thrown in boyhood, after receiving the education which the schools of Peebles afforded, upon his own resources, William was apprenticed to a printer in Edinburgh, whither the family had moved, and afterward opened a book stall; while Robert, failing to obtain the collegiate education which he desired with a view to the university, at the age of 16 also opened a book stall. Until 1832 the brothers conducted separate establishments. William eked out the profits of his small trade by working at case and press, and in 1830 published his "Book of Scotland," an elaborate and comprehensive account of the usages and institutions, the schools, social system, and civil and religious organization of that country. Meantime Robert, sharing in the enthusiasm which was then introducing the national element so largely into Scottish literature, had published in 1823 "Illustrations of the Author of Waverley," a pleasant anecdotal volume, which at once attracted for the young author the notice of the leading literary men of Edinburgh. In 1824 appeared his "Traditions of Edinburgh," an authentic, detailed, and amusing account of the old memories and associations in which the various localities of that capital are so rich. It was dedicated to Sir Walter Scott, who had communicated to him valuable materials for it. This was rapidly followed by his "Popular Rhymes of Scotland" (1826), "Picture of Scotland" (1827), "History of the Rebellion of 1745-'6," "Life of James I.," and three volumes of "Scottish Songs and Ballads" (1829). In 1829 the brothers united their efforts in preparing the "Gazetteer of Scotland," which was completed and published in 1832, having been written for the most part by them in the intervals of business. In February, 1832, appeared the first

number of the "Edinburgh Journal," designed "to supply intellectual food of the best kind, and in such a form and at such a price as must suit the convenience of every man in the British dominions." It immediately attained a circulation of 50,000, whereupon the brothers united their places of business into one establishment. This journal has remained till the present time one of the most widely circulated of British periodicals. In 1834 they began the publication of a series of scientific and historical treatises, written in a popular style, under the title of "Information for the People," the average sale of the numbers of which was above 100,000 copies. They were followed by the "Biographical Dictionary of Eminent Scotchmen" (1835); "Cyclopædia of English Literature" (1844), at once historical and biographical, with well chosen extracts from the works of the principal British authors of every age; the "People's Edition of Standard English Works," "Papers for the People," "Miscellany," "Repository of Instructive and Entertaining Tracts," and other collections, all of which were in a cheap form and widely read. "Chambers's Educational Course," which has been completed by degrees, includes works in almost every branch of knowledge, and covers the entire ground from first lessons to accomplished scholarship. Robert Chambers devoted much time and attention to literary and scientific pursuits, while William was the business man of the firm. Among Robert's later productions are "Ancient Sea Margins" (1848); the "Life and Works of Burns" (4 vols., 1851-'2), the profits of which he generously gave to the poet's surviving sister; "Essays from the Journal" (4 vols.); "The Domestic Annals of Scotland" (1858); "The Book of Days" (1864); "Essays" (1866); and with his brother "Chambers's Encyclopædia" (10 vols. 8vo, 1860-'68; new ed., 1871-'2). He was also, without doubt, the author of the "Vestiges of the Natural History of Creation," a work remarkable for the force with which it advocates the so-called development theory. Satisfactory evidence of Robert Chambers having written this work is contained in letters to his life-long friend and correspondent William Wilson of Poughkeepsie, N. Y. He received the degree of LL. D. from the university of St. Andrews, whither he retired from active business, and spent the last three years of his life. William Chambers has contributed numerous essays to the "Journal," has given his impressions of the United States in works entitled "Things as they are in America," and "Slavery and Color in America" (1854); and is the author of "Peoples and its Neighborhood," "About Railways," "Wintering at Mentone," "Youth's Companion and Counsellor," and "Improved Dwelling Houses for the Humble and other Classes in Cities," suggested by his experience in improving the dwellings of his tenantry on his estate of Glenomiester near Peebles, the cultivation and improvement of which forms a

pleasant relaxation for his well earned leisure. He has presented to his native town, at a cost of £30,000, a substantial building and an excellent library known as the "Chambers Institution," and has served two terms as lord provost of Edinburgh. In 1872 he published "Memoirs of Robert Chambers, with Autobiographical Reminiscences."—The publishing house of W. and R. Chambers is the largest in Scotland, employing more than 300 persons. The style of the firm remains unchanged, Robert Chambers's place being occupied by his eldest son Robert. They have also a publishing establishment in London, which was conducted until his death by David, a younger brother of William and Robert, who was admitted into the firm.

CHAMBERSBURG, a borough and the capital of Franklin co., Pennsylvania, situated on Conecocheague creek, and on the Cumberland Valley railroad, 45 m. S. W. of Harrisburg and 135 m. W. of Philadelphia; pop. in 1870, 6,308. Turnpike roads connect it with Baltimore, Pittsburgh, and Philadelphia. The surrounding country, which forms part of the great limestone valley at the S. E. base of the Blue mountains, is populous and highly cultivated. There are manufactories of cotton, wool, flour, paper, and iron. The houses are mostly of brick or stone. The borough has a fine court house, a national bank with a capital of \$260,000, and 10 churches. It is the seat of Wilson college, an institution for the education of young ladies, under the control of the Presbyterians, which in 1871 had 9 instructors and 81 students. Three weekly newspapers and two monthly periodicals are published here. Chambersburg was set on fire by the confederates under the command of Gen. Early, during a raid into Pennsylvania, July 30, 1864, and two thirds of the town was destroyed.

CHAMBERTIN, a famous vineyard of France, in the department of Côte d'Or, 6 m. S. S. W.

of Dijon. It is about 60 acres in extent, divided among several proprietors. The annual produce rarely exceeds 150 pipes of red wine, which ranks among the best of Burgundy.

CHAMBERY (Ital. *Ciamberi*), a town of France, capital of the department of Savoie, situated within a circle of high mountains, on the rivulets Leisse and Albane, affluents of Lake Bourget, 44 m. S. S. W. of Geneva; pop. in 1866, 18,297. It is a picturesque town, with fine pleasure grounds and a bustling appearance, and is steadily increasing in prosperity owing to its situation on the railways from France to Switzerland and Italy. It is the seat of an archbishop. The remains of the ancient castle of the counts and dukes of Savoy are situated on a lofty eminence, with charming gardens and sloping terraces; only three of the towers, the chapel, and part of the building have escaped the fires of 1745 and 1798. The chapel is built after the model of the Sainte Chapelle in Paris, with fine lancet windows of painted glass. The prefecture is in the castle yard, which also contains the apartments formerly reserved for the use of the royal family of Sardinia. The most conspicuous monument, consisting of a fountain with figures of elephants, was erected in honor of Gen. de Boigne, who amassed a large fortune in India, and who appropriated more than 3,000,000 francs to hospitals and other benefactions in this his native place. The church of Lémene, on a rock near the Leisse, is the oldest in the district, and contains in the crypt the tomb of an Irish bishop. Among the other principal churches are the Gothic cathedral and the church of Notre Dame, in the Doric style. There were formerly 20 monasteries, of which only three convents and four nunneries are left. The finest modern public buildings are the theatre, the palace of justice, the town hall, the barracks, and a covered market. The principal educational institutions are an academy, a lyceum,

Chambéry.

a theological and normal seminary, and a school for the deaf and dumb. There are a museum of art and science, a public library with about 20,000 volumes and many important manuscripts, and a number of learned associations and charitable institutions. The Chambéry silk gauzes have long been renowned, and laces, silk, and woollen hosiery, hats, watches, and many other articles are manufactured here. An active trade is carried on in cereals, cattle, wine, leather, copper, raw silk, and other commodities.—Chambéry was ruled by counts in the 11th and 12th centuries, and in the 13th it became the capital of Savoy. It was occupied by the French in 1535, from which time it was alternately in their possession and in that of the native rulers till 1713, when Louis XIV. finally restored it to the dukes of Savoy by the treaty of Utrecht. After the French revolution it was once more under French domination as the capital of the department of Mont Blanc till 1815, when it was restored to Sardinia. In 1860 it came finally into possession of France with the rest of Savoy.

CHAMBLY, a S. W. county of the province of Quebec, Canada, bordering on the right bank of the river St. Lawrence, opposite the

island of Montreal; area, 189½ sq. m.; pop. in 1871, 10,498, of whom 9,755 were French. It is watered by the Richelieu and Montreal rivers, one being a continuation of the other, and contains an expansion of the Richelieu called the basin of Chambly, 2 m. in diameter, of nearly circular form, and interspersed with islands. On the W. side of the basin stands Fort Chambly, built by the French in 1711. In the southern part of the county there is a mountainous elevation. Chambly, sometimes erroneously supposed to imply wheat field, is the name of the original grantee of the seignior. The Champlain and Montreal and the Grand Trunk railways and the Chambly canal traverse the county. Chief town, Chambly, on the Richelieu, 12 m. E. S. E. of Montreal.

CHAMBORD, a village of France, in the department of Loir-et-Cher, 9 m. E. of Blois; pop. in 1866, 332. It is noted for its château, surrounded by a beautiful park, 21 m. in circumference. The counts of Blois had here a hunting lodge and pleasure house, built in 1090. It was added to the possessions of the crown by Louis XII., and torn down by Francis I. to make way for the present magnificent structure, which was commenced after designs

Castle of Chambord.

by Primaticcio, and continued in subsequent reigns; but the original plans were never carried out. Diana of Poitiers resided here, and the letters H. and D. entwined with a crescent still fill the compartments of the vaulted ceilings. Charles IX., Louis XIII., and Louis XIV. occasionally held their court here; and Molière gave here the first representation of his *Bourgeois gentilhomme*. Chambord afterward became the residence for some years of Stanislas Leszczynski, ex-king of Poland. In 1745 Louis XV. bestowed it upon Marshal Saxe, who restored much of its former brilliancy. After his death, and that of his nephew the count de Frise, the château reverted to the crown; it was bestowed upon the Polignac

family by Louis XVI. in 1777, plundered by the mob in 1792, and sold as national property. In 1809 Napoleon gave it to Berthier, whose widow sold it in 1821 for nearly 1,800,000 francs to the legitimists, who presented it to the infant duke of Bordeaux, hence called count de Chambord.

CHAMBORD. I. Henri Charles Ferdinand Marie Diendonné, count de, duke of Bordeaux, the representative of the elder branch of the French Bourbon dynasty, called by his partisans Henry V. of France, born in Paris, Sept. 29, 1820, seven months after the assassination of his father, Prince Charles Ferdinand d'Artois, duke de Berry. (See BERRY, DUCHESS OF.) The title of duke of Bordeaux was given him in com-

pliment to the legitimist zeal of that city, and that of count de Chambord after the estate of that name, presented to him by his partisans. He had among his tutors the baron Damas and Gen. d'Hautpoul; and after the revolution of July, 1830, during which his grandfather Charles X. and his uncle the duke d'Angoulême in vain resigned their rights in his favor, he lived in exile successively in Scotland, Austria, and for a short time in Italy, till 1845, when he established himself in London, where the large fortune which had been bequeathed to him by the duke de Blacas enabled him to live in fine style. In 1851, after the death of the duchess d'Angoulême, he inherited the domain of Frohsdorf, near Vienna, where he has since generally resided, having sold his palace in Venice in 1866. In August, 1850, he attended a gathering of legitimists at Wiesbaden, and in February, 1872, at Antwerp. He clings to the traditional Bourbon theory of the divine right of kings and of devotion to the see of Rome, from time to time issues manifestoes in this sense to the French nation, and firmly rejects all overtures aiming at a reconciliation with the house of Orleans at the expense of his principles; but has always refrained from violent assertions of his claims to the throne. In August, 1870, he gave 10,000 francs and the use of his château for the relief of wounded French soldiers and sailors, and in the summer of 1871 for the first time returned to France, but voluntarily left the country after a short stay at Chambord. **II. Marie Thérèse Béatrice Gaétane**, countess de, archduchess of Austria, wife of the preceding, born July 14, 1817. She is the eldest daughter of Francis IV., duke of Modena, and of the princess Maria Beatrice of Sardinia, great-granddaughter of Maria Theresa, and grand-niece of Marie Antoinette. Her sister married Don Juan de Borbon, and became the mother of Don Carlos, duke of Madrid. On Nov. 16, 1846, she married at Bruck, Styria, the count de Chambord. She is a highly accomplished princess, and takes much interest in the improvement of the working classes; and during the German war she attended to the sick and wounded French soldiers in Belgium and Switzerland.

CHAMBRAY, Georges, marquis de, a French soldier and author, born in Paris in 1783, died about 1850. He belonged to an ancient Norman family, and received the highest military education. He served in the Napoleonic wars, and was captured by the Russians, who banished him to the Ukraine, where he remained till the fall of Napoleon. From 1823 to 1829 he filled various military positions. His writings include *Philosophie de la guerre* (1827; 2d ed., 1829; continuation, 1835), and *Histoire de l'expédition de Russie* (2 vols., 1833; new ed., 3 vols., 1835), which acquired a European reputation.

CHAMBRE ARDENTE, a name originally applied in France to courts hung with black, and lighted by torches, where criminals of the high-

est rank were tried. Subsequently any extraordinary court of law was called *chambre ardente*; as for instance the tribunal which in 1535 was established by Francis I. for the special purpose of trying heretics. Under Louis XIV. the *chambres* were opened in 1679 for the purpose of trying Mme. de Brinville, and other prisoners, and were then also called *cour des poisons*; but in 1680, after the execution of Mme. Voisin, the *chambres ardentes* were again closed. The extraordinary courts under the regency (1716), where the trial of the farmers of the public revenue took place, and those instituted for the registration of the shares of John Law, the financier, were also known as *chambres ardentes*.

CHAMBURE, Auguste Lepelletier de, a French soldier, born at Vitteaux, Burgundy, March 31, 1789, died of the cholera in Paris, July 12, 1832. By his audacity in the Napoleonic wars in Spain and Germany, and especially at Dantzic in 1813, he became known as *le diable*, and his *corps franc* of 100 men as the infernal regiment. After the capitulation of Dantzic he surrendered to the prince of Würtemberg, who sent him as a prisoner to Presburg. He was released in 1815 and restored to a military command in France; but in 1816 he was accused of a highway robbery upon two English officers, fled to Belgium, and in his absence was sentenced to hard labor for life. Pardoned in 1820, he prevailed upon Ary Scheffer and other eminent artists to prepare designs for his *Napoléon et ses contemporains*, which work achieved success owing to its magnificent illustrations. After the accession of Louis Philippe he became attached to the staff of Marshal Soult, minister of war.

CHAMELEON (*chamaleo*, Brongn.), a genus of saurian reptiles, inhabiting the warmest parts of Africa and India. The genus is characterized by teeth on the upper edge of the jaws, toes united into two groups, prehensile tail, and body compressed and covered with squarish scales, with or without a series of spiny processes along the back, belly, chest, and tail. The skin is chagreened with small scaly grains, the back is sharp, the tail round and slender. There are five toes on each foot, divided into two parcels, one of two and the other of three, each united by the skin as far as the claws. The tongue is fleshy, cylindrical, and capable of an elongation of six or seven inches; the teeth are trilobed; the eyes are large, almost covered by the skin, except a small hole opposite the pupil, and are capable of movements independent of each other. The back of the head is raised in a pyramidal form; there is no visible external ear; the first rib is united to the breast bone, the rest being continued to their fellows of the opposite side, enclosing the abdomen in an entire circle. The lungs are large, and admit of great inflation. The most common species is the *chamaleo vulgaris* (Lacép.), so well known to travellers in Egypt and northern Africa. Many other species are described

from the Seychelles islands, Isle of Réunion, Mauritius, and the Cape of Good Hope. The chameleon is well described by Aristotle in his "History of Animals." The name is derived from the Greek, and signifies little lion, or, as some maintain, camel lion. There is probably no animal about which more prejudices and errors have existed from the remotest antiquity than the chameleon. The two most remarkable faculties attributed to it are those of being able to live on air, and of changing color according to the objects to which it comes near; the first it certainly does not possess, and the latter but partially. Like all other reptiles, it can remain for months without eating, which, with its sudden changes of bulk, gave rise to the opinion that it lived on air. Chameleons eat flies and other insects, which they seize by means of their long sticky tongues, the only part of their bodies which they move with any vivacity. It is true that the chameleon changes its colors with great rapidity, but the changes are not determined by the colors of surrounding objects, nor by the greater or less amount of blood sent

Chameleon (*Chamaëlo vulgaris*).

to the skin. Other reptiles possess this power of changing color, as also do many fishes, as the *coryphæna* (vulgarly called dolphin), and many of the mollusks, as the argonaut and the squid. It has been ascertained by experiments that the varieties of color in the squid are due especially to changes in the surface of the skin from the voluntary contractions of the muscular fibres in the dermis, modifying the reflections from the pigment spots as well as from the colorless portions of the skin. It is probable, considering the scaly character of its skin, that similar surface reflections, from contraction of the muscular fibres of the dermis, are the causes of the changes of color in the chameleon; and that the inflation of the lungs and body, and the changes in the cutaneous circulation, are merely secondary agents. The natural color of the animal is a fine green, tinged in some parts with reddish brown and grayish white; from this the hues vary to deep bluish green, yellow, blackish, and various shades of gray; the colors are the brightest in the warmest and sunniest weather. They are often seen

of the same colors as surrounding objects, which they doubtless assume instinctively as a means of protection against their numerous enemies. The chameleon can also inflate its body even to its feet and tail, by slow and irregular motions; this in a moderate degree may aid the muscular contractions of the skin in the production of its brilliant surface changes. The chameleon moves very slowly; it will remain for days on the branch of a tree, to which it fixes itself very firmly by means of its peculiarly divided feet and prehensile tail. This slowness of motion, and the absence of all defensive and offensive weapons, render it an easy prey to its enemies. Whether upon a tree or on the ground, it is an awkward animal. The native Africans and Asiatics consider chameleons harmless creatures, and even pet them in their dwellings on account of their destruction of insect pests. When kindly treated they are very gentle, but they readily fight with each other, slowly opening and shutting their jaws, like the blades of scissors. The female lays about a dozen eggs, which she deposits in the sand, leaving them to be hatched by the heat of the sun. Were it not for their great fecundity the species would soon be destroyed.

CHAMFORT, or **Champfort**, **Sébastien Roch Nicolas**, a French author, born near Clermont, in Auvergne, in 1741, died in Paris, April 13, 1794. He received a superior education, became successively a lawyer's clerk, a tutor, and secretary of a gentleman of Liège, and a writer for the *Revue encyclopédique*. He had to contend with many difficulties till 1764, when the successful performance of his comedy *La jeune Indienne* improved his prospects. His play *Le marchand de Smyrne* (1770) is regarded as his masterpiece, though his tragedy *Mustapha et Zéangir* (1776) was more successful, chiefly owing to the partiality for it of Louis XVI., and particularly of Marie Antoinette; and a pension of 1,200 livres was granted him, besides a salary of 2,000 livres as secretary of the prince of Condé. He soon resigned the latter employment to join Mme. Helvétius at Auteuil, who had befriended him during his early struggles. After having won several academical prizes, and one for the best *éloge* on La Fontaine, instituted by Necker in the hope that La Harpe, who was among the competitors, would win it, Chamfort was admitted to the academy in 1781. He afterward became reader to Madame Élisabeth, for whom he prepared a commentary on La Fontaine's fables. Smarting to some extent under the patronizing manners of French princes and nobles toward men of letters in their employ, he sympathized with the revolution, and the title of the pamphlet of Sieyès on the *tiers état*, as well as the saying *Guerre aux châteaux, paix aux chaumières*, and other pithy utterances, have been ascribed to him. He prepared for Mirabeau his *Discours sur les académies*, and also assisted Talleyrand in some of his reports. But subsequently he was frightened by the excesses of

the terrorists, and defined the doctrine of equality as signifying *Sois mon frère ou je te tue*. Placed under arrest, he was released after a few days and resumed the directorship of the national library, to which he had been appointed. His arrest being again determined upon, he inflicted serious wounds upon himself while attempting to blow out his brains and to cut his throat with his razor, declaring that he would rather die by his own hand in the full enjoyment of his liberty than submit to the slavery of a dungeon. He was restored to health, but a relapse ended his life. Mirabeau called him *une tête électrique*, and Grimm, Chateaubriand, and Sainte-Beuve all refer to his influence. M. Auguis published the most complete edition of his works, with a notice of his life and writings (5 vols., Paris, 1824-'5). See also *Œuvres de Chamfort*, by Arsène Hous-saye (1852), and *Pensées, maximes, anecdotes, dialogues*, with a biography of Chamfort, by P. J. Stahl (new enlarged ed., with letters from Mirabeau to Chamfort, 1860).

CHAMISSO, Adalbert von, or Louis Charles Adelaïde de Chamisso de Boncourt, a German poet and naturalist, born at Boncourt, France, Jan. 27, 1781, died in Berlin, Aug. 21, 1838. He went in his boyhood to Berlin, where he became a page of the queen of Prussia, and studied at the French gymnasium. He was a lieutenant from 1798 to 1806, when he returned to France; but he went again to Berlin in 1811 to study natural history. He accompanied Otto von Kotzebue as naturalist in Count Rumiantzef's expedition around the world, 1815-'18, was subsequently employed in the botanical garden in Berlin, and was a member of the academy of sciences. He wrote the famous story of *Peter Schlemmühl* (1814; 9th ed., Hamburg, 1867; new illustrated ed., 1868), which has been translated into the principal foreign languages. Among his *Gedichte* (17th ed., Leipsic, 1861) are many poems which gave him a foremost rank among the lyrical poets of his country. They fill the 3d and 4th volumes of his *Gesammelte Werke* (6 vols., 1836-'9; 5th ed., 1864), the first two volumes containing his *Reise um die Welt*, and the 5th and 6th his biography and correspondence. His other publications include another work on his travels, one relating to botany, and one upon the Hawaiian language. With Varnhagen von Ense he edited for some time the *Musenalmanach*.

CHAMOIS, or Gems (*antelope rupicapra*, Pallas), the mountain or Alpine antelope of Europe, and the only animal of that geographical division which partakes in any degree of the character of the antelopes. It is found in the Pyrenees, the Alps, the Carpathian and Grecian mountains, the Caucasus and Taurus ranges, the heights of the Himalaya, and perhaps in other situations of similar character. The chamois is rather more than 3 ft. in length, and a little above 2 ft. in height. Its smooth black horns are about 6 in. long, rising nearly perpendicularly from the fore part of the brow,

abruptly hooked backward at their extremities, and nearly parallel through their entire extent. It is beardless, but the body is covered with a short thick fleece of fine wool, to protect the animal from cold, and also with long and silky hair of a deep brown color in winter, brown fawn color in summer, and slightly mixed with gray in spring. The head is silvery yellow, the inside of the thighs and ears white, and the tail black. A small black band winds from the corner of the mouth around each eye. The kids are of a deep yellow color. Impatient of heat, the chamois remains in the summer on the loftiest ridges, or in snowy valleys, clipping for its food the mountain herbs and the tender shoots of shrubs, and rarely drinking. It is remarkable for its agility, and for its keenness of sight and smell. It scents a man at a long distance, is at once thrown into great agitation, and flies at its utmost speed on his first appearance. It bounds from rock to rock with an admirable grace, and ascends and descends

Chamois (*Antelope rupicapra*).

cliffs which few other animals would attempt. It is more closely allied to the prong-horn (*antelope Americana*) than to any other species of antelope. The structure and form of their horns are nearly similar; and the pelage of each of the two animals is peculiar, though not identical. It is, in some respects, a connecting link between the true antelopes and the goats, although far more closely allied to the former. The chamois is easily tamed, and becomes very familiar and fond of the persons who feed it. The venison is but moderately good, bearing some resemblance to that of the roebuck, but inferior in flavor and quality. The skin is dressed into a fine light leather, in use for under garments, and for cleaning plate, glass, and the like; though but a small quantity of what is sold as chamois, or, as it is usually termed, shammy leather, is actually made from the hide of this animal.—Of all sports, the pursuit of the chamois is the most difficult and perilous.

It is also the least profitable, so rare is the beast becoming even in his most difficult and remotest haunts, so small are the chances of success, and so little the value of the game when taken.

CHAMOMILE (Gr. *χαμαί*, on the ground, and *μήλον*, apple; *anthemis nobilis*, Linn.), a plant of the family *compositæ*, indigenous in the south of England, and widely cultivated in gardens for medicinal use. Its leaves and daisy-like flowers emit a strong perfume when trodden upon. The flowers have long been famous as an aromatic bitter. A tepid infusion of them, known as chamomile tea, is often employed as an emetic. They are used externally as fomentations in colic and intestinal inflammation.

Chamomilla medicinalis.

Chamomile is naturalized in many parts of Europe, and in the state of Delaware. *Anthemis cotula*, wild chamomile, and *matricaria chamomilla*, German chamomile, a plant of the same family, have similar properties.

CHAMORRO, Fruto, a Central American statesman, born in Guatemala in 1806, died March 12, 1855. He belonged to an old and wealthy Spanish family, but joined the national cause and became a member of the legislature of Nicaragua and of the constituent assembly, and a senator (1838-'42); and when in 1843 an attempt was made for a partial confederation of San Salvador, Honduras, and Nicaragua, he was chosen supreme delegate with executive power. He retired in 1844, after having averted a war declared against Guatemala. Subsequently he became civil and military governor of S. Nicaragua, and in 1851 secretary of the treasury; and after the outbreak in August which drove Pineda from power, he succeeded him as general-in-chief.

He was chief magistrate, or supreme director, in 1853-'4, and was defeated by a body of insurgents, and besieged for nearly 300 days at Granada, the besiegers retiring Feb. 10, 1855.

CHAMOUNI, Chamouny, or Chamonix, a picturesque Alpine valley of France, between the Graian and Pennine Alps, in the department of Haute-Savoie, over 3,000 feet above the Mediterranean, and about 2,000 feet above the lake of Geneva, watered by the river Arve. It is more than 13 m. long and 2 m. broad, and is bounded N. by Mont Brévent and the Aiguilles Rouges, N. E. by the Col de Balme, S. W. by Monts Lacha and Vandagne, and S. by the chain of Mont Blanc, whence rise enormous glaciers. The largest of these, the Mer de Glace, is broken by many deep crevices disclosing the remarkable purity and deep blue coloring of the frozen mass. The winter, which lasts from October to May, is very severe; snow lies three feet deep in the lowest part, and the routes over the mountains are altogether impassable. The short summer, however, is warm. In July commences the dangerous labor of driving cattle across the Montanvert and the Mer de Glace, to pasture on the mountains beyond; and the occasion is made a holiday. One man is left on the other side of the glacier, to guard the cattle till autumn. The soil, though naturally barren, yields when carefully cultivated good crops of grain and fruit, and affords pasturage for cattle. The rearing of bees is one of the principal industries of the valley, and the white aromatic honey of Chamouni is renowned. Fancy articles of carved wood are manufactured, and the inhabitants are also engaged in spinning and weaving. Numerous excursions are made from Chamouni to the Montanvert, leading to the Mer de Glace; to the Pierre Pointue and glacier des Bossons, the Flégère, and the Brévent; to the Jardin, a flowery island in the midst of a sea of ice; to the

Chamouni, with Mont Blanc in the distance.

Grands Mulets, and to Mont Blanc. The finest views of the latter mountain chain, of Mont Maudit and Mont Blanc du Tacul, and other conspicuous scenery, are from the Bré-

vent, and from the Flégère, the peak of the former mountain. About 300 horses and mules and many skilled guides are at the disposal of tourists, under strict regulations of the authorities and of the Alpine clubs. The first recorded visit to this region is that of a bishop of Geneva in 1443. Philip of Savoy, count of Geneva, licensed fairs here in 1530; and the mountains have been explored occasionally by Swiss and Germans. But the glaciers inspired so much dread that the valley was believed to be covered with snow in order to punish the inhabitants for their sins; and they were styled *les montagnes maudites*, the accursed mountains. In 1606 St. Francis de Sales visited the valley, which was within his diocese of Geneva. In 1741 the attention of the English was attracted to the region by the reports of Wyndham and Poccoke; and an inscription on a block of granite, popularly known as the English stone, on the spot near the Mer de Glace, where these travellers were erroneously supposed to have passed the night, having been accidentally destroyed, has been restored on Mont Montanvert. De Saussure made his first visit to the valley in 1760, and Bourrit in 1775. In December, 1859, Tyndall explored the Mer de Glace, and crossed the channels of its avalanches in the deep snow, encountering perils which are great in winter, although in summer the passage is comparatively safe. There are several villages in the valley, with an aggregate population of about 2,000. The principal of these is Chamouni, on the right bank of the Arve, about 22 m. S. E. of Bonneville, at the foot of Mont Blanc. The distance to the nearest railway station, at Martigny, is about 22 m., which may be traversed on mules in nine hours by the passes of the Tête Noire or the Col de Balme. The village is also known as Le Prieuré, from a Benedictine priory established by a Genevese count, with the sanction of Pope Urban II., toward the close of the 11th century. An English chapel was opened in 1860. In August and September the place is overcrowded with visitors, and presents a bustling appearance. Flax and honey are exported, and there are a mine of anthracite, called Du Coupeau, and mineral warm baths. The origin of the name Chamouni is traced to *champs munis*, or fortified grounds, in allusion to the natural fortifications formed by the mountains.

CHAMPAGNE, an ancient province of France, bounded N. by Belgium, E. by Lorraine, S. E. by Franche-Comté, S. by Burgundy and Nivernais, and W. by Orléanais, Ile de France, and Picardy. Capital, Troyes. For a long time it was governed by local princes, and was united to the crown of France in the 14th century. At present it comprises the departments of Aube, Marne, Haute-Marne, Ardennes, and part of the departments of Seine-et-Marne, Aisne, Yonne, and Meuse. It is chiefly celebrated for its wines, containing about 125,000 acres of vine-growing land.

The present department of Marne, however, alone produces what is technically known in commerce as champagne wine. The department of Ardennes produces a common red wine, which is exclusively consumed by the inhabitants. The best of it is wanting in body, spirit, and color, and will not bear exportation or keeping. Of the product of the department of Haute-Marne, about one half is consumed at home, the remainder being sold in the vicinity. The quality of these wines is superior to those of Ardennes. The department of Aube produces a red wine, the larger portion of which is reserved for home consumption. The better classes of wine are strong-bodied and heady, requiring to be kept at least two years before they are fit for use. Some excellent white wines are produced here. The department of Marne has about 46,000 acres of vineyards, which produce red and white wines, one third of which, principally the former, is consumed within the department, the rest forming one of the great staples of the commerce of the district. The arrondissements of Rheims and Épernay contain the most celebrated vineyards. (See FRANCE, WINES OF.)

CHAMPAGNE, or *Champaigne*, **Philippe de**, a French painter, born in Brussels, May 26, 1602, died in Paris, Aug. 12, 1674. In 1621 he went to Paris, where he became a friend of Nicolas Poussin, superintendent of one of the royal galleries, and a successful portrait and landscape painter. His portraits, especially one of himself, are remarkable for the characteristic excellence of coloring of the Flemish school. Among the finest of his other works are those at the Carmelites, in Paris.

CHAMPAGNY. **I. Jean Baptiste Nompère**, count de, duke de Cadore, a French statesman, born at Roanne, Aug. 4, 1756, died in Paris, July 3, 1834. He belonged to a junior branch of an ancient family, studied under Laplace, distinguished himself in the naval service, and was severely wounded while serving under De Grasse, April 11, 1780. In 1789 he became a member of the states general, was arrested in 1793, but escaped, and entered the council of state in 1799. In 1801 he went as ambassador to Vienna, and in 1804 Napoleon made him minister of the interior. He was at the emperor's coronation in Milan in 1805, and received the portfolio of foreign affairs in 1807. In 1809 he was present at the battle of Wagram, and assisted in the treaty of peace which resulted in Napoleon's marriage with Maria Louisa. He urged the annexation of the Netherlands and of other territories to France. In 1811 he was dismissed from the ministry for having failed to comprehend Napoleon's designs against Russia. He adhered to Napoleon during the hundred days, although Louis XVIII. had made him a peer. In 1830 he supported Louis Philippe. His *Souvenirs* were published at Paris in 1846. **II. Louis Alix Nompère de**, duke de Cadore, eldest son of the preceding, born Jan. 12, 1796, died in

Boulogne in January, 1870. He entered the chamber of peers in 1835, but retired from politics on the fall of Louis Philippe. In 1861 he was French ambassador at Rome. He married a daughter of Count Lagrange.

III. François Joseph Marie Thérèse, count de, brother of the preceding, born in Vienna, Sept. 10, 1804. He coöperated with Montalembert and Beugnot in various publications, and in 1869 succeeded Berryer as a member of the French academy. His principal works are *L'Histoire des Césars* (4 vols., 1841-'3; 2d ed., 1853) and *Les Antonins* (3 vols., 1863; 2d ed., 1866). **IV. Napoléon Marie de Nompère**, count de, brother of the preceding, born in Paris, Oct. 29, 1806. Napoleon was his godfather. He became an advocate, but devoted himself to agriculture. He supported the second empire, and in 1851 was elected deputy for Morbihan, and reelected in 1863 and 1869. He has published *Traité de la police municipale*, &c. (4 vols., 1844-'61). **V. Jérôme Paul de Nompère**, brother of the preceding, became a member of the legislative body for the department of Côtes-du-Nord in 1853, and was reelected in 1863 and 1869.

CHAMPAIGN. I. A W. central county of Ohio, intersected by Mad river; area, about 390 sq. m.; pop. in 1870, 24,188. The surface is level or undulating, and the soil fertile. It is traversed by the Cincinnati, Sandusky, and Cleveland, the Pittsburgh, Cincinnati, and St. Louis, the Atlantic and Great Western, and the Springfield branch of the Cleveland, Columbus, Cincinnati, and Indianapolis railroads. The chief productions in 1870 were 724,360 bushels of wheat, 1,280,472 of Indian corn, 244,073 of oats, 74,277 of potatoes, 21,082 tons of hay, 344,401 lbs. of butter, and 169,060 of wool. There were 7,696 horses, 5,463 milch cows, 8,673 other cattle, 38,103 sheep, and 20,810 swine. There were 15 manufactories of carriages and wagons, 1 of agricultural implements, 5 of furniture, 2 of glue, 12 of saddlery and harness, 3 of sashes, doors, and blinds, 2 of woollen goods, 20 flour, 3 planing and 20 saw mills, 4 tanneries, and 2 currying establishments. Capital, Urbana. **II.** An E. central county of Illinois, comprising a part of the Grand Prairie, and watered by several streams; area, about 880 sq. m.; pop. in 1870, 32,737. The surface consists of an open plain of great fertility, interspersed with small clusters of trees. It is traversed by the Toledo, Wabash, and Western, the Chicago branch of the Illinois Central, the Indianapolis, Bloomington, and Western railroads, and a branch railroad from Urbana to Decatur. The chief productions in 1870 were 245,668 bushels of wheat, 45,752 of rye, 3,924,720 of Indian corn, 721,375 of oats, 266,918 of potatoes, 44,800 tons of hay, 35,273 lbs. of cheese, 716,430 of butter, 66,986 of wool, and 53,588 gallons of sorghum molasses. There were 16,529 horses, 8,565 milch cows, 18,516 other cattle, 17,313 sheep, and 36,384 swine. There were 15 manufactories of car-

riages and wagons, 2 of boots and shoes, 6 of bricks, 4 of furniture, 11 of saddlery and harness, 2 of sashes, doors, and blinds, 1 of woollen goods, 1 machine shop, 10 flour and 8 saw mills. Capital, Urbana.

CHAMP DE MARS. I. The name given to the annual meetings held by the Frankish tribes who took possession of Gaul during the 5th century. They were called in Latin *Plactia*, while the Frankish appellation was *Mäls*. These meetings were sometimes military reviews, or solemn national assemblies, where all the freemen among the Franks gathered to pay homage to the supreme chief of the nation; sometimes special assemblies of the lords and warriors, called by the king to consult upon some military expedition, or of the bishops, to take their advice upon some point of general policy, or adjust some interior difficulty. Under the first Carolingians the time of these meetings was changed from March to May, whence they were called *Champ de Mai*. **II.** The name of an immense oblong square, situated on the outskirts of Paris, between the *école militaire* and the Seine, and especially devoted to the drilling of troops and military pageants. It is 3,280 ft. long by 1,640 wide, is flanked by ditches faced with stone, has four rows of trees on each side, and is entered by five gates. The first great feast of the French revolution, the *fête de la fédération*, was celebrated here. On that occasion, the place not being ready, the population of Paris, of both sexes and all ranks, went to work by night and day, and completed it by the day, July 14, 1790. On July 17 of the following year the place was the scene of a great demonstration against the legislative assembly, which ended with a sanguinary dispersion of the crowd by Lafayette; in 1793, of the acceptance of the constitutional act voted by the convention; in 1794, of the feast of the Supreme Being, with Robespierre as its leading performer; in 1796, of the rejoicings on account of the taking of Milan by Bonaparte. On June 1, 1815, Napoleon held here the great assembly, known as the *Champ de Mai*, for the acceptance of the supplementary act to the imperial constitution. Here in 1827 the review was held in consequence of which the Paris national guards were disbanded by Charles X. The republican feast of agriculture and industry was celebrated here in 1848. Louis Napoleon distributed eagles here to the soldiers. May 10, 1852, and made a speech to them which was regarded as a prelude to the formal establishment of the second empire. Here was held the universal exposition of 1867.

CHAMPE, John, an American soldier, born in Loudon co., Va., in 1752, died in Kentucky near the close of the 18th century. He was selected from Gen. Lee's regiment, by request of Washington, to go to New York as a deserter and spy, and if possible to seize and bring off Arnold after the execution of Major André. Champe undertook the enterprise, passed the American lines with difficulty, was

hotly pursued by his comrades as a deserter, reached New York, underwent an examination before Sir Henry Clinton, and by him was consigned to Arnold, who gave him in the British army his former rank of sergeant major. He discovered Arnold's habit of walking in his garden at a late hour every night, and formed a plan with a comrade to seize and gag him there, and to take him between them as a drunken companion to a boat on the Hudson, whence arrangements were made for his speedy transportation to the American headquarters. On the appointed night Arnold failed to appear in the garden, and Champe, after waiting for him till near morning, returned with chagrin to his position in the British army. It proved that Arnold had the day before changed his quarters, preparatory to the embarkation of his troops for Virginia. Champe embraced the first opportunity to escape to the American army, and joined the troops under Gen. Greene. Gen. Washington discharged him from further service, lest, falling into the hands of the enemy, he should be hanged. When subsequently Washington sought for him to reward him for his faithful and dangerous service, he learned of his recent death in Kentucky.

CHAMPERTY (Lat. *campi partitio*), an agreement between a party to a suit and some third person that the latter shall carry on the suit at his own expense, and in consideration thereof shall receive a portion of what is recovered therein in case of a successful result. It differs from maintenance in that in the latter case the question of compensation does not necessarily enter into the account. At the common law, not only was the agreement void, but the entering into it was a misdemeanor, and statutes were passed to punish cases analogous in character and in supposed mischief. Of late, however, the tendency has been to relax the old rules, from a conviction that, whatever may have been the case formerly, the evils that might flow from such bargains are rather imaginary than real. By statute in some of the United States it is legal for a party to make such bargain with his attorney as he may consider for his interest; and judicial decisions have modified the old rules considerably where no such statutes exist. It was a very ancient rule of the common law that chases in action should not be assigned, the object of which rule was to prevent any champertious intermeddling with claims to be put in suit; but courts of equity long since recognized the right of the assignee, and no other effect of the rule remained except that it was required that a suit at law should be brought in the name of the assignor. But this has now been abrogated in a number of the states, and assignees may sue at law in their own names, subject, however, to all legal defences and offsets which existed against the claim in the hands of the assignor at the time of notice of the assignment.

CHAMFLEURY, the popular name of JULES FLEURY, a French author, born at Laon, Sept. 10, 1821. He is the son of a municipal officer, became clerk in a publishing house in Paris, described his literary and journalistic struggles in *Confessions de Sylvius* and *Les aventures de Mariette*, wrote *Contes d'hiver, de printemps, d'été et d'automne*, and acquired fame by his *Chien-Caillou* (1847), and by his pantomimes, which led in 1863 to his becoming director of the Funambules theatre. In 1848 he was one of the founders of the *Événement* newspaper, and in 1849 he wrote *Les oies du Noël* for Proudhon's *Voix du Peuple*. Prominent among his numerous works is *Les bourgeois de Molinchart* (1854), a satire on provincial life, which placed him at the head of the realistic school. A collection of his writings was published in 1857 under the title of *Œuvres complètes* (partly republished in his *Œuvres illustrées*), which has since been increased by many volumes, including his *Histoire de la caricature antique et de la caricature moderne* (2 vols., 1865; new ed., 1872).

CHAMPION, a term derived from chivalry, and signifying one who undertakes to defend his cause by force of arms. Custom allows a wider latitude of application to the word. In the ruder stages of society, when might constituted right, the right was frequently submitted to such an arbitrament. The two elements which then chiefly entered into the social system, namely, religion and love of military glory, both inclined toward a ceremony in which God should be called to indicate the righteousness of the cause by success in the trial by battle. Accordingly, we find from the earliest ages of feudalism the trial by private combat recognized as a legal mode of settling disputes. The trial came gradually to be hedged in by formalities, until it was only appealed to in cases of grave import. It is obvious that in many cases of personal encounter the disputants must be so unequally matched that they could not be pitted against each other with any chance of a fair result; the law therefore permitted the plaintiff or the defendant in cases of accusation to name a proxy or champion. Appeal to combat could be made in court martial, that is to say, in cases coming under the jurisdiction of the court of chivalry or honor, in appeals of felony, and in certain cases upon issue joined in a writ of right. Ladies and minors, being disqualified by reason of their physical incapacity, prosecuted their claims by a champion. The champion usually challenged his opponent by casting down his glove, which the latter accepted by taking it up. Combat was then joined, and carried on to the death, or till stopped by the judges. Verdict was given for the victorious party. It is from this custom that our modern phrase is derived, "to appeal to the God of battles." Judicial combat appears to be of Gothic origin. William the Norman introduced it into England, where it was practised as late as 1638.

In the 13th year of Queen Elizabeth a trial of battle was fought by champions in Tothillfields, Westminster, on a writ of right. The custom was suppressed in France by St. Louis in 1270, but remained unrepealed on the English statute book to the time of George III., when a highwayman escaped from justice by claiming an appeal to wager of battle. In the ceremonies until recently in use on the coronation of the kings of England, a champion figured conspicuously. The championship of England is hereditary in the family of Dymocke, whose eldest male representative heir, armed *cap-a-pie* in the style of the middle ages, should ride into the ring, and throwing down his gauntlet dare any one to dispute the right of the sovereign to the throne. This portion of the ceremonial last occurred in 1821, at the coronation of George IV. William IV. and Victoria dispensed with it.—The knight who during a tournament had charge that insult or injury be not offered or done to the ladies assembled was also called a champion.

CHAMPLAIN, a N. W. county of the province of Quebec, Canada, on the left bank of the St. Lawrence; area, 229 sq. m.; pop. in 1871, 8,167, of whom 8,015 were French. It is traversed by the rivers St. Maurice, Champlain, Batiscan, and Vermilion, and copiously watered by small streams and lakes. The surface rises gradually from the St. Lawrence; the soil is fertile and the timber of excellent quality. To the ordinary agricultural products, this county adds tobacco and a considerable quantity of maple sugar. Chief town, Batiscan.

CHAMPLAIN, a township forming the N. E. extremity of Clinton co., New York, on Lake Champlain, and a village 5 m. S. W. of Rouse's Point; pop. of the township in 1871, 5,080; of the village, 1,850. The village is situated on Chazy river, which supplies it with water power, and is connected by the Ogdensburg and Lake Champlain railroad with Rouse's Point and Ogdensburg. It is comprised in Champlain collection district, and has some trade, which is carried on by the Chazy river. The village contains several churches, an academy, and manufactories of iron.

CHAMPLAIN, Lake, lies between New York and Vermont, and extends from Whitehall in the former state to St. John's in Canada. It is 126 m. long, and varies in breadth from 40 rods to 15 m. Its greatest breadth unobstructed by islands is about 10 m., at a point near Burlington, Vt. Its outline is very irregular, the shores being indented by numerous bays. Its depth varies from 54 to 282 ft., and the largest vessels can navigate its whole extent. The principal islands are North Hero, 11 by 2 m., South Hero, 13 by 4 m., and La Motte, 6 by 2 m.; these three, with several smaller ones and the peninsula of Alburg, all in the N. part, form the county of Grand Isle in Vermont. There are about 50 smaller islands. The principal rivers entering the lake are Wood creek, at its head, the outlet of Lake George, the Au

Sable, Saranac, and Chazy, from New York; the Otter, Winooski, Lamoille, and Missisque, from Vermont. The outlet of Lake Champlain is the Sorel or Richelieu river, sometimes called the St. John's, which empties into the St. Lawrence, and with the Chambly canal affords a passage for vessels of large size to the ocean. On the south it communicates, by means of the Champlain canal, with the Hudson river. Navigation is usually closed by ice about the end of November, and opens early in April. The waters abound with bass, pickerel, salmon trout, and other varieties of fish. This lake, filling a valley enclosed by high mountains, is celebrated for its magnificent scenery, embracing the Green mountains of Vermont on the east and the Adirondack mountains of New York on the west. Several pleasant villages and watering places, with one or two important towns, are situated on its shores, which comprise the collection districts of Burlington and Champlain.—Lake Champlain was discovered in 1609 by Samuel Champlain, whose name it received. It was the scene of important events in the early wars of the continent, and in 1814 of a considerable naval battle. At that time an invasion of the northern portion of New York was contemplated by the British, and a force of from 10,000 to 15,000 troops was collected in the vicinity of Montreal for that purpose. In such an expedition the command of Lake Champlain became an object of great moment, as it flanked the march of the invading army for more than 100 m., thus offering facilities for the transportation of reinforcements and supplies. The efforts of both nations were therefore directed to the creation of naval forces on the lake in the shortest possible time. The Saratoga, the largest American vessel, was built at Vergennes, and was launched on the 40th day after the first tree used in her frame was taken from the forest. In August, 1814, the English army, about 12,000 strong, commanded by Sir George Prevost, advanced along the western shore to Plattsburgh, which was held by Gen. Macomb with about 1,500 men. The American naval force, under Capt. Macdonough, was anchored in Plattsburgh bay; it consisted of 14 vessels of all classes, carrying 86 guns and about 850 men; the largest vessel was the Saratoga, 26 guns and 212 men. The British squadron, under Capt. Downie, consisted of 16 vessels, carrying 95 guns and about 1,000 men; the largest vessel was the *Confiance*, 37 guns and 300 men. At sunrise on Sept. 11 the British squadron came in sight, and by 8 o'clock approached the American fleet. Fire was opened by the Americans, which was not returned by the enemy until the *Confiance* had anchored at about 300 yards from the American line. The first broadside from the *Confiance* killed or wounded 40 men on board the Saratoga, nearly a fifth of her entire complement, and more than a third of the American loss during the action. The engagement now became general.

In an hour the whole starboard battery of the *Saratoga* was disabled. She was then winded about by means of kedges which had been laid from the bows, and her fresh broadside was brought to bear upon the *Confiance*, which had also suffered severely. The British vessel attempted to perform the same evolution, but without success, and after fighting about $2\frac{1}{2}$ hours in all was forced to strike her flag. The fire of the *Saratoga* was then turned upon the brig *Linnet* of 16 guns, the second vessel of the enemy, which surrendered in a few minutes. The *Chubb* sloop of 11 guns had meanwhile struck to the *Ticonderoga* of 17 guns, and the *Finch* sloop of 11 guns had been crippled, and, drifting within reach of a single gun planted on a small island, also surrendered. These sloops had been captured from the Americans the year before. The 12 gunboats which made up the remainder of the British squadron also hauled down their flags, but presently made off and escaped, all the men on the American gunboats being required to keep the prizes afloat. The American loss in killed and wounded was 112; that of the British is estimated at from 173 to 204, exclusive of prisoners. Of the 95 guns which they brought into action, they lost all but 20. The American victory was mainly owing to the precaution of Macdonough in throwing out kedges from the bows of the *Saratoga*, so that when the guns in one broadside were disabled, she could be turned round and present a fresh broadside to the enemy. Her 26 guns were thus in this action practically equal to twice as many. In fact, with these, she actually outfought the *Confiance* and the *Linnet*, with 53 guns of fully equal calibre, having together twice as many men, but which could not, when one broadside was disabled, turn round and fight with the other. The British army under Prevost had in the mean time advanced upon Macomb's position at Plattsburgh. A feint was made in front, while a column was sent to ford the river above, and take it in the rear; but the column lost its way, and before the ford could be found the naval battle was over. The attack was at once abandoned, and under cover of night and a storm the British retreated in disorder, leaving behind their sick and wounded, and a part of their baggage and stores.

CHAMPLAIN, Samuel de, a French navigator, founder of Quebec and first governor of New France, born at Brouage, in Saintonge, in 1567, died Dec. 25, 1635. He was of a family long connected with the sea as fishers and mariners, his father being a ship captain. He evidently received a careful education as a navigator, but early in life entered the army and rose to the rank of quartermaster of cavalry in the army of Brittany against the league. His uncle was pilot general of the fleets of the Spanish king, and as such conducted back to Spain the troops who had served in France. Champlain went with him, and took command of the *St. Julien*, which sailed in January,

1599, for Mexico, as one of a Spanish fleet, returning to Spain in March, 1601. Of his voyage he drew up a faithful report, with views and charts. This *Bref discours* was printed for the first time at Quebec in 1870, although a translation had appeared in the publications of the Hakluyt society. On his return he received a pension from Henry IV., and was urged by the commander De Chaste, governor of Dieppe, to explore and prepare to found a colony in territories in North America which had been granted to him by the king. He accordingly sailed March 15, 1603, in the ship of Pontgravé, an experienced navigator of St. Malo. They anchored at Tadoussac, where the Saguenay enters the St. Lawrence, May 24. He then, with Pontgravé and a few men, ran up the river in a light boat till they were stopped by the sault St. Louis rapids above Montreal. He then returned to Tadoussac, carefully examining both shores of the river. While the Indian trade was going on, he explored the river St. Lawrence down to Gaspé, preparing a map, and collecting information as to mines said to exist in Acadia. He then returned to France, where in 1603 appeared his first volume, *Des sauvages*, giving an account of his exploration. His patron, the commander De Chaste, had died meanwhile, and his privileges had been transferred to Du Guay, sieur de Monts. Champlain was too important to be overlooked. De Monts made an engagement with him, and resolving to form a settlement in Acadia, they sailed together, and reached Sable island May 1, 1604. They then ran along the coast of Nova Scotia, and finally began a settlement on the island of St. Croix, in a river of the same name, between what is now Maine and New Brunswick. Finding it inconvenient, after wintering there they removed to Port Royal, near the present Annapolis. During the years 1604-16 Champlain explored the coast as far as Cape Cod, making careful surveys and maps. In 1607 he returned to France. Having suggested to De Monts the greater security of a post on the St. Lawrence, and its greater importance from its commanding the trade of a large inland territory he was sent out in 1608 with Pontgravé. After reaching Tadoussac he ran up the St. Lawrence, and arriving on July 3 at the place called Quebec, or the Narrows, by the Algonquins, he decided to make the settlement there. They had scarcely begun to clear the ground and build when a plot was formed by five wretches to assassinate Champlain and escape to a foreign ship at Tadoussac. This was happily thwarted, and the ringleader punished on the spot. In 1609 Champlain, who had gained the good will of the Montagnais on the St. Lawrence, joined them in an expedition against the Iroquois. A party of Algonquins and Hurons met them, and the combined force ascended the Sorel river to the Chambly rapids. Here Champlain sent back his boat and crew, and proceeding on in a canoe, entered and

named Lake Champlain. Meeting a large Iroquois force on the lake, both parties landed and threw up bulwarks of trees. They engaged next day, and Champlain, killing two Iroquois chiefs and mortally wounding another with his arquebuse, decided the day. The Iroquois fled, and were pursued by the allies, who killed and took many. By this step Canada became a party to the Iroquois war, which lasted with occasional intermissions till the end of the French rule. In September Champlain returned to France, leaving Pierre Chavin of Dieppe in command at Quebec. De Monts had lost some of his privileges, but not his zeal for exploring America. Champlain sailed back in March, 1610, with a number of mechanics. The Montagnais again called for his aid, which he gave, to obtain their cooperation in his explorations. An Iroquois force on the Sorel was attacked and their fort stormed, Champlain receiving a severe wound in the action. Hastening back to France again in 1611, he left Du Parc in his place, and married Helen Boullé, a girl of 12, who was then a Protestant, but who outlived him to die as an Ursuline nun. He made a short visit to Canada, but returned to France to labor for it there. De Monts had lost his influence, the merchants interested had grown tired of the expense, and the whole scheme of colonization was about to be abandoned. Champlain induced the count de Soissons to take the matter in hand, and that nobleman obtained a commission appointing him governor and lieutenant general of New France, Oct. 8, 1612. Champlain was appointed his lieutenant a week later, and received the same position under the prince de Condé, who shortly after succeeded to the rights of De Soissons. He sent over some vessels, but in 1613 sailed himself to explore the Ottawa, which one Vignau pretended to have ascended to a lake, and thence to the North sea, where he had seen the wreck of an English ship. He left St. Helen's island, near Montreal, so called in honor of his child wife, May 27, 1613; but on entering the Ottawa he soon discovered Vignau's fraud. Champlain however arranged better terms for the fur trade, and returning to France formed a trading company, and in 1615 brought over Père Denis Jamay and two other Recollect priests, with a lay brother, to attend to the spiritual concerns of the new colony. One of these, Père Caron, immediately set out for the country of the Hurons on Georgian bay. Champlain followed by the tedious Ottawa route, and taking command of a force entered the present New York territory to attack the palisaded town of the Entouohoron, members or allies of the Iroquois league. Owing to the insubordination of his Hurons he was repulsed in his assault, and received two wounds in the knee and leg. He was carried back to their town, and on his recovery visited the Tionontates and Ottawas, and in the spring returned to Quebec and France. For

some years Canada languished, and Champlain was actively engaged on both sides of the Atlantic to save it from utter extinction. When the duke de Montmorency succeeded Condé in 1620, Champlain grew more sanguine, and brought over his young wife, who remained till 1624, often experiencing great hardship. The De Caens, merchants, had now acquired the trade; Quebec was fortified and began actually to increase, when the duke de Ventadour in 1625 acquired the viceroyalty, and went energetically to work to build up Canada, and sent over the first Jesuit missionaries to aid the Recollects in winning the natives to Christianity. A new danger menaced the struggling colony. In July, 1628, an English fleet under David Kirk and his two brothers, born in France though of English origin, summoned Champlain to surrender Quebec. His answer was so bold that Kirk retired after committing some depredations. The Canada company, formed by Cardinal Richelieu, had just sent out settlers and provisions. On these Champlain depended, but Kirk intercepted and captured the fleet; and Champlain, after wintering at Quebec in great distress, surrendered to Louis and Thomas Kirk July 19, 1629. He was nearly recaptured on his way down the St. Lawrence by Emery de Caen, but was carried to England, and subjected to some harsh treatment. By the treaty of St. Germain-en-Laye, concluded in 1632, Canada was restored; and Champlain, reinstated as governor, sailed from Dieppe in 1633, with three vessels, well equipped. He was welcomed by the settlers and the Indians. The Jesuit missionaries resumed their labors among the Indians, while he did all in his power to develop the colony and strengthen it against future attack, establishing a post on Richelieu island, and founding Three Rivers. He did not long survive, dying two years after his arrival, and leaving Bras de Fer de Châteaufort to direct the colony till the arrival of a new governor.—Champlain, apart from his merits as a discoverer, was a noteworthy man. His zeal for the propagation of Christianity was great. A saying of his is preserved, that the salvation of one soul is of more importance than the founding of a new empire. While in Canada he devoted himself wholly to the duties of his position, and apparently with a single eye to benefit his patrons. Although traffic with the Indians was very lucrative, he never engaged in it. His views of justice were stern and upright, yet tempered with mercy. He has been accused of credulity in repeating the stories told him by the Indians, but he does not express his own belief in them. Besides the volume *Des sauvages*, in 1603, he published *Voyages* in 1613, with very valuable charts of the New England coast; *Voyages*, 1619 (reprinted 1627); and in 1632 a volume containing a very badly executed abridgment of the previous voyages, without their valuable maps, and a continuation from 1619. The volume contains

also a catechism in Huron, and prayers in Montagnais. Some copies bear date 1640. It was reprinted at Paris in 1830, without maps. As scholars required all the voyages to know what Champlain really wrote, two clergymen of Quebec, the abbés Laverdière and Casgrain, well known for their historical studies, in 1870 published the whole series, including his Mexican voyage, in 6 vols. 4to, with notes and facsimiles of all the maps and illustrations. There is also in the *Mercure Français*, vol. xix., his account, apparently, of the voyage of 1633.

CHAMPLIN, Charles Josuah, a French painter, born at Les Andelys, June 6, 1825. He studied under Drolling, produced his first work, a female portrait, in 1845, and subsequently succeeded in delineations of Auvergnese mountaineers, and in portraits and fancy pictures. His "First Roses," representing a semi-nude girl with fresh roses on her lap, attracted much attention in 1857, and was purchased for the Tuileries; and he was employed in 1860 in decorating that palace, and afterward the flower saloon and the bath room of the empress Eugénie in the Élysée. The excessive realism of his female figures led to the exclusion of his famous *Aurore* from the exhibition of 1859. Napoleon III. subsequently authorized the publication of an engraving of it.

CHAMPMESLÉ. I. Marie Desmares, a French actress, born in Rouen in 1644, died at Auteuil in 1698. Her father, the son of a president of the parliament of Normandy, being disinherited on account of his *mésalliance*, and obliged to engage in business, she took to the stage, married an actor, and in 1669 went with her husband to Paris, where the reputation they had acquired in Rouen was increased by their performances. In 1670 she personated Hermione at the hôtel de Bourgogne, and Racine, at first skeptical, became so delighted with her pathetic genius, that he gave her instruction in acting, caused her to play the principal characters of his tragedies, became her lover, and was said to have written *Phèdre* for her. She was as celebrated for her beauty and amiability as for her genius and amours. The wits and courtiers thronged her house, and one lover succeeded another. Boileau, while extolling her genius, satirizes her as Claudia; and when Racine was supplanted by the count de Clermont-Tonnerre, the wags said that her passion for the great dramatist had been *déracinée par le tonnerre*. She performed at the Comédie Française from the time of the foundation of the theatre in 1680 till a little while before her death. **II. Charles Chevillet**, popularly known as Champmeslé, husband of the preceding, a French playwright and comedian, born in Paris in 1645, died in 1701. He was the son of a tradesman, and after his marriage he acquired some fame as a comedian, especially in ridiculing the class of society from which he sprang. He was a friend of La Fontaine, and was believed to have coöperated

with him in writing plays. The most noted of his own productions was *Le Parisien*, a comedy performed in 1682, the success of which was mainly due to the performance by Madame Guérin, the widow of Molière, of one of the principal parts. Notwithstanding his wife's unfaithfulness, he retained his love for her, and died suddenly while he was having the anniversary of her death commemorated in the church.

CHAMPOLLION-FIGEAC, Jacques Joseph, a French archaeologist, born at Figeac in 1778, died in the palace of Fontainebleau, May 9, 1867. He was at first librarian of the public library and professor of Greek literature at Grenoble. In 1828 he removed to Paris, being appointed professor at the *école des chartes*, and keeper of the manuscripts in the royal library, which office he retained till 1848. In 1849 he was appointed librarian at the palace of Fontainebleau, and remained in that office till his death. He edited many valuable manuscripts connected with the history of France, most of them under the patronage of the government or the French historical society; aided Sylvestre de Sacy and Dacier in several important publications; and superintended the unfinished publications of his brother, especially the *Grammaire égyptienne*, the *Dictionnaire hiéroglyphique*, and the *Voyage en Égypte*. In 1864 he completed, in 76 folio plates, his *Monographie du palais de Fontainebleau*. His subsequent works include *Le palais de Fontainebleau*, &c. (2 vols., 1867), and *Documents paléographiques relatifs à l'histoire des beaux-arts et des belles-lettres pendant le moyen âge* (1868).—One of his sons, AIMÉ CHAMPOLLION, has published a series of biographies and historical works, including *Louis et Charles d'Orléans*, &c. (2 vols., 1844).

CHAMPOLLION LE JEUNE, Jean François, a French Egyptologist, brother of the preceding, born at Figeac, Dec. 23, 1791, died in Paris, March 4, 1832. He studied so diligently under the direction of his brother that he permanently injured his left eye. His introduction to a new geographical work on Egypt (1807) increased the reputation which previous scientific disquisitions had established for him among the eminent orientlists of Paris, under whose guidance he perfected his acquirements. He commenced his studies of hieroglyphics in 1808, discovered the 25 Egyptian letters mentioned by Plutarch, and used them so skilfully in transcribing Coptic writings, that a member of the academy published them as an Egyptian work of the Antoninian period. In 1809 he became professor at the newly established university of Grenoble, when he began to announce and partly to publish the results of his researches, which made him celebrated as the founder of Egyptology, and especially of the science of hieroglyphics. The political events of 1815 led him to retire from his chair till 1818, when he resumed for a time his lectures on history and geography. Soon afterward he

went to Paris, where he read before the academy his dissertation *Sur l'écriture hiéroglyphique et démotique*, and his *Analyse méthodique du texte démotique de Rosette*, which Sylvestre de Sacy praised as prodigious efforts of learning and genius. In 1822 he read before the academy of inscriptions his celebrated disquisition, afterward published under the title of *Lettre à M. Dacier*, which proved his discovery of the hieroglyphical alphabet, both Arago and De Sacy deciding in favor of Champollion's priority of discovery as against Thomas Young, whose English partisans have claimed this honor for him. His subsequent expositions of the figurative, idiographical, and alphabetical systems of hieroglyphics was published in 1824 by the French government, under the title of *Précis du système hiéroglyphique des anciens Égyptiens*. In the same year, after examining the collection of the French consul at Turin, subsequently acquired by the king of Sardinia, he announced the discovery of the celebrated royal or chronological papyrus. He next visited Rome and Leghorn, and his report, made at the instance of the duke de Blacas, on the Egyptological collection of Henry Salt, the English consul at the latter city, led to its acquisition by the museum of Paris. He returned to Rome, where he described the Turin collection in his *Lettres à Monsieur le duc de Blacas* (2 vols., Paris, 1824-'6); and successfully applying his system to the interpretation of the monuments at Naples and Florence, he prepared the catalogues of the royal collection. Pope Leo XII. requested him to prepare a new work relating to the obelisks of Rome, but of this only the designs were published, the Latin work on this subject brought out in 1842 being spurious. Soon after the establishment of the Egyptian museum at the Louvre (1826) he became its director and lecturer, and his classification was adopted in the other museums of the kind. He exposed the fallacies of Klaproth and other savants, and summed up in 1827 the result of previous investigations in his *Aperçu des résultats historiques de la découverte de l'alphabet hiéroglyphique*. Charles X. gave him the entry to his court by appointing him officer of the royal household, placed a frigate with seven draughtsmen and an architect at his disposal for the exploration of Egypt and Nubia (1827-'30), and in 1831, after the accession of Louis Philippe, the chair of Egyptian archaeology was created for him at the collège de France. He retired to a country seat to compose his *Grammaire égyptienne* (1836-'41), which became a standard work for that science, and his *Dictionnaire égyptien* (1842-'4). The letters to his brother during his Egyptian journey were published in 1835. He proposed to make his personal observations the basis of a comprehensive work, but lived only to publish the prospectus. After an attack of apoplexy at the close of 1831, he foresaw his speedy end, and employing January and February of 1832 in revising his Egyptian grammar, he handed the

work to his brother, saying that he hoped posterity would accept it as his visiting card. His death was mourned not only on account of his labors, which, as Chateaubriand said, "will be remembered as long as the immortal monuments which they revealed," but also on account of his great virtues. A monument was erected to him at Figeac, with inscriptions prepared by the institute. His bust was placed in the museum of Versailles, and copies of it were executed for the towns of Figeac and Grenoble; and his memory is perpetuated by an inscription in the royal museum of Turin. His MSS. were purchased by the French government, and edited under the supervision of his brother (1834-'48). After his death appeared *Monuments de l'Égypte et de la Nubie* (4 vols. 4to, 1835, with 400 folio plates); *Mémoires sur les signes employés par les anciens Égyptiens à la notation des divisions du temps* (1841); and fragments of *Notices descriptives* (1844).

CHANCEL, that portion of a church specially occupied by the clergy, and usually separated from the nave and aisles by screens made of carved stone or oak. The screen which separated the chancel from the nave was formerly called the rood screen, because a rood or large crucifix was usually placed on it, accompanied with two figures representing St. John and the Virgin Mary. In the chancel were situated the high altar, the *sedilia*, or seats for the officiating clergy, and the *piscina*, in which the water used for washing the hands of the celebrant was poured. It was usually surrounded with carved seats or stalls, which were occupied by the clergy not engaged in the services. These were also used when the office was sung in choir, a lecturn being placed in the centre of the chancel. The stalls were usually enriched with carvings, and had canopies of carved oak placed over them. The chancel in Gothic buildings occupies the place of the apsis in the ancient basilicas, and was called so from the *cancelli* or rails which were used in the early churches to separate the clergy from the laity.

CHANCELLOR, a law officer known to the polity of several countries. The derivation of the title is uncertain. It has been derived by Coke from the right of cancellation of patents and other royal grants, inherent in this officer, for misrepresentation of facts or on other grounds. But the word chancel would point to a more ancient derivation. The *cancellarius* of the Roman courts was simply a doorkeeper, or usher, to keep back the people who pressed rudely forward to the *cancelli*, or railings. The doorkeeper afterward became chief scribe, an official which the Roman church borrowed from the Roman empire, and still retains in the bishop's chancellor. The function of the chancellor of Great Britain is thus described by Blackstone: "When the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor, with different jurisdictions and dignities, according to the different constitutions.

But in all of them he seems to have had the supervision of all charters, letters, and such other public instruments of the crown as were authenticated in the most solemn manner, and therefore, when seals came into use, he had always the custody of the king's great seal; so that the office of chancellor, or lord keeper, whose authority by the statute of Elizabeth is declared to be exactly the same, is with us created by the mere delivery of the king's great seal into his custody, whereby he becomes, without writ or patent, an officer of the greatest weight and power of any now subsisting in the kingdom, and superior in point of precedence to every temporal lord. He is a privy councillor by his office, and prolocutor of the house of lords by prescription. To him belongs the appointment of all justices of the peace throughout the kingdom. Being formerly an ecclesiastic, for none else were then capable of an office so conversant in writing, and presiding over the king's chapel, he became keeper of the king's conscience, visitor in right of the king of all royal hospitals and colleges, and patron of all the king's livings under the value of 20 marks (or £20) per annum. He is the general guardian of all infants, idiots, and lunatics, and has the general superintendence of all charitable uses in the kingdom, and all this over and above the vast and extensive jurisdiction which he exercises in his judicial capacity in the court of chancery." The chancellor of England is a member of the cabinet, and as such retires on a change of ministry. This union of judicial and political functions was always an impediment to justice, and, as the public business takes precedence, gave rise to great inconvenience in the business of the court. By act of parliament passed in 1851, the chancellor was relieved of a considerable part of his judicial duties by the appointment of two lords justices, who together with the chancellor constituted a court of appeals for the review of cases brought from the vice chancellors and master of the rolls, all causes being heard in the first instance by the officers last named, or any two of them. The jurisdiction of the several courts of chancery is now transferred to and merged in that of the supreme court of England, created by act of Aug. 5, 1873. (See CHANCERY.) The chancellors of England have usually been distinguished for great legal attainments as well as political weight. Lords Eldon, Brougham, Cottenham, and St. Leonards have been the most distinguished of the present century. The last named chancellor (formerly known as Sir Edward Sugden) had an important part in the measures for the reform and improvement of the court of chancery. During a temporary vacancy in the office of chancellor, or when the chancellor is incapacitated from the performance of his duties, the great seal is put in commission; that is, intrusted to commissioners, who perform the duties of the office. The legal style of the chancellor is lord high

chancellor of Great Britain, and he takes precedence next to the archbishop of Canterbury, and above all dukes not of the blood royal. He has a salary of £10,000, with a retiring pension of £5,000. The office of chancellor of Scotland was abolished on the union of the two kingdoms. The lord high chancellor of Ireland has an authority within that kingdom corresponding in most respects to that of the lord high chancellor of Great Britain. His salary is £8,000, with a retiring pension of £3,692. The chancellor of the duchy of Lancaster has local equity jurisdiction.—The chancellor of the exchequer in Great Britain is under treasurer and the principal minister of finance. As such he is a member of the cabinet. Formerly he had judicial duties in connection with the court of exchequer, but these are now nominal. The chancellor of Oxford or Cambridge is the chief officer of those collegiate bodies. He is elected, and his office is honorary, the duties being discharged by the vice chancellor. The chancellor of a bishop sits in the consistorial court, and is theoretically the bishop's assessor and legal adviser. Various orders of knighthood have an officer called chancellor, and there is also the chancellor of a cathedral, who superintends the regularity of religious services.—In continental Europe there are various political as well as ecclesiastical officials styled chancellors. The chancellor of France was one of the highest officials of the old monarchy. The office was closely analogous to that of England. The chancellor was president of the great council and of the parliaments, drew up ordinances and letters patent, and held the royal seals. It is connected with the illustrious names of Duprat, De l'Hôpital, Birague, Maupeou, Malesherbes, and other distinguished jurists. Louis XV. held the seals himself for a time; and in 1757, the censorship having been associated with the other duties of the office, the virtuous Malesherbes, deeming executive and police duties incompatible with the purity of the judicial office, resigned. It was abolished in 1790, and revived for a short time by Napoleon, merely that his court might be graced with the title, for the functions were not restored. Revived under the restoration, it was finally abolished in 1838.—Only a few of the United States ever established the office of chancellor. In New York it existed until 1848, and was filled by able jurists, of whom James Kent is most celebrated. In some of the other states the office was also filled with marked ability, but it is retained now only in New Jersey and Delaware, though in Alabama, Mississippi, and Tennessee there are district chancellors, chosen by popular vote. The duties of the office where it exists in the United States are purely judicial.

CHANCELLORSVILLE, Battle of, fought in Spottsylvania county, E. Virginia, May 2-4, 1863, between the Union army of the Potomac under Gen. Hooker, and the confederate army

of North Virginia under Gen. Lee. Hooker replaced Burnside in command of the army of the Potomac, Jan. 26, 1863. He found it somewhat demoralized by the defeat at Fredericksburg and by dissensions among its principal officers, but by the middle of April he had brought it to a high state of efficiency. It numbered 132,000 men, of whom 13,000 were cavalry. It was divided into seven corps, under Reynolds, Couch, Sickles, Meade, Sedgwick, Howard, and Slocum, the cavalry being under Stoneman. It lay in camp on the left bank of the Rappahannock, opposite Fredericksburg. The confederate army was intrenched on the heights across the river. It was divided into the corps of Longstreet and Jackson, but Longstreet himself, with three of his five divisions, had been sent to North Carolina, so that there remained 62,000 men, of whom 3,000 were cavalry under Stuart. The position was thought to be unassailable in front, and Hooker undertook to turn its left flank, and so fall upon its rear. In the mean while he sent all his cavalry, with the exception of 1,000, upon an expedition to cut the communications of the enemy with Richmond. On the morning of April 27 a column 36,000 strong, which comprised the greater part of the corps of Meade, Howard, and Slocum, moved up the left bank of the Rappahannock 27 m. to Kelly's ford, beyond the extreme confederate left, where they crossed without opposition. Meade then moved down the opposite bank 10 m. toward the United States ford, brushed away three brigades which defended it, so that Couch, who was waiting on the other side with 12,000 men, crossed, and the four corps moved by different roads toward Chancellorsville, which had been designated as the place of rendezvous. They were in light marching order, encumbered with little artillery or baggage, the ammunition being carried by mules; and before the night of the 30th 48,000 men had reached Chancellorsville, and Sickles with 18,000 more was only a few hours' march behind. So successfully had the movement been conducted, that Hooker was justified by every military consideration in declaring that "the enemy must either ingloriously fly or come out from behind his intrenchments and give us battle on our own ground, where certain destruction awaits him." Chancellorsville was a solitary brick mansion, surrounded by a few outbuildings, standing in a clearing on the verge of a wild region known as the Wilderness. The tract, 10 or 15 m. in extent each way, had formerly been covered with a heavy forest. This had been cut down to supply fuel for the iron furnaces, and the soil being too poor to repay cultivation, a dense growth of dwarf pines, scrub oak, chinquapins, and brambles had sprung up. The surface was varied by low ridges, swampy intervals, and muddy brooks. Here and there was a solitary church, tavern, or farm house, each in a little clearing. Two main roads traverse the Wilderness from E. to W. These,

coming from Culpeper and Orange Court House, unite near Chancellorsville, and after two or three miles again diverge, both running toward Fredericksburg, 11 m. E. of Chancellorsville. The other roads are little more than wood paths. The battle of Chancellorsville was fought near the eastern border of this tract; that of the Wilderness, a year later, about 10 m. to the west. Sedgwick and Reynolds had crossed the Rappahannock below Fredericksburg, and were making a threatening demonstration on the confederate front, and it was not till the evening of the 30th that Lee was aware that his left flank had been turned, and that Hooker was in his rear, with a force fully equal to his own. Directing Early with 10,000 men to hold the heights of Fredericksburg, he at once called up Anderson from the left, and ordered Jackson to march from the extreme right. Jackson's main force was 20 m. distant. He began to move at midnight; at 8 o'clock the head of his column began to come up to Anderson, and by 11 on Friday morning, May 1, all had arrived, and were drawn up in line of battle in front of the Wilderness, out of which the enemy was now beginning to move. Hooker had done much, but he had omitted the one thing which would have insured success. An hour's march, the evening before or this morning, would have taken him unopposed out of the Wilderness and into the open country. But now, at noon, as his columns debouched by different roads, they found the enemy advancing in force; and, in opposition to the opinion of every one of his generals who had touched the enemy, he fell back again into the Wilderness. "The passageway," he says, "was narrow; I was satisfied that I could not throw troops through it fast enough to resist the advance of Gen. Lee, and was apprehensive of being whipped in detail. Accordingly, instructions were given for the troops in advance to return and establish themselves on the line they had just left, and to hold themselves in readiness to receive the enemy." The enemy, barely 50,000 strong, had come out of his intrenchments, and Hooker with more than 60,000 retreated before them from the ground which he himself had chosen, abandoned the offensive and assumed the defensive, while at the same time he had, 15 m. away, 56,000 more who were only hindered from falling upon what was now Lee's rear by the 10,000 left with Early. Hooker's defensive line was nearly in the shape of the letter **C**, the main front facing southward, the upper and lower curves looking west and east. The corps and divisions were somewhat broken up. Meade was on the left, nearest Fredericksburg, Slocum in the centre, Howard on the right. The corps of Couch and Sickles were mainly in reserve, but a division from each was thrust forward into the front line. Howard's position was weakly posted, being in military phrase "in the air;" but as the enemy were wholly on the left, hardly reaching to the centre, it was

thought safe. Skirmishers pushed into the woods informed Lee that the Union front was unassailable; but a cavalry reconnoissance disclosed the exposed situation of the Union right, and during the night Lee and Jackson resolved to attack there. To do this the confederate force must be divided. Jackson with 30,000 men was to move by a forest road around the Union position, while Lee with 20,000 kept up a show in front. Jackson moved at daybreak; a mile of dense forest shut him from the view of the enemy; only about 9 o'clock the road crossed a bare hill, over which the long column was plainly seen moving. It was clearly a movement in force, but its object was uncertain. The road just there ran southward, the direction which a retreat would probably take; but it might be for offence upon the right, and Howard was ordered to be on the alert, and especially to throw out pickets in his front. At 3 o'clock Jackson had accomplished his circuit of 15 m., which brought him within 6 m. of the point from which he had set out. He halted to form his men in an open space 2 m. to the west of Howard's position. Scouts creeping through the woods discovered the Union intrenchments unguarded; the arms were stacked, the men preparing their dinner. At 5 o'clock Jackson burst upon them down the road and through the woods on each side. The regiments on whom the shock first fell scattered without firing a shot, and the whole corps broke in disorder, and swarmed down the road to within half a mile of Chancellorsville. But the pursuers were checked from two quarters. All day Lee kept up a noisy demonstration on Hooker's front. Pleasonton, with two regiments of cavalry and a horse battery, had pushed a little into the woods, and finding nothing for cavalry to do was riding leisurely back. He came upon an open space, now filled with men, ambulances, and guns, the debris of a part of Howard's corps. The low underwood was swarming with the enemy. He ordered one regiment to charge into the woods to check the pursuit for a few minutes, while with the other he brought up his horse battery, got a score of other guns into position, and had all of them double-shotted with canister and pointed low. The check given by the cavalry to the confederates was but momentary; they dashed straight toward the guns, but their line was swept back by the artillery; again and again they pressed on, and were again repelled, and at last fell back into the cover of the forest. As the Union line had been placed, Hooker had at Chancellorsville only Berry's division of Sickles's corps and a brigade of Couch's. With Berry's division he vainly tried to check the fugitives, some of whom were shot down by his staff. Berry's division then pressed straight through the flying crowd, and poured a fire of artillery up the road and into the woods. This brought the pursuers to a stand. Jackson, with a small escort, had ridden out to reconnoitre. Turn-

ing back, he was fired upon by his own men, who mistook the company for enemies. He received several wounds, from which he died a week later. Hill, the next in rank, was also wounded soon after, and the command devolved upon Stuart. In this action Hooker had suffered nothing beyond the partial disorganization of Howard's corps, the weakest in the army; the ground lost was of no consequence; and moreover Reynolds's large corps arrived during the night from Fredericksburg. —On Sunday morning, May 3, Hooker still stood on the defensive; he indeed ordered a new line to be drawn up, to which he might fall back in case of need. Lee had in the mean time communicated with Stuart, and given orders that "those people should be pressed." Hooker now had at and about Chancellorsville fully 78,000 effective men; Lee proposed to press him in his intrenchments with barely 50,000. The Union force was all together; the confederates were separated by six miles of almost pathless forest, and it depended upon the chances of battle whether these could be reunited. Moreover, Sedgwick, who had with him 27,000, might fairly be expected to be able to drive off the 10,000 of Early, and appear on the field, as he was now ordered to do. Then, could both commanders concentrate their whole force, Hooker would have 95,000, Lee at most 60,000. Hooker's line now formed three sides of an irregular square. The left, facing eastward, was held by Hancock's division of Couch's corps; the centre by Slocum; the right, facing westward, by Sickles and French's division of Couch's corps. Reynolds was halted two miles in the rear of the extreme right; Meade was partly in reserve, and partly guarding the road leading to the river; Howard was on the extreme left, where no attack was anticipated. These last three corps took no part in the action of the day. Sickles's extreme left had been at Hazle Grove, apparently pushed beyond the general line, and exposed to attack. Hooker directed him to withdraw from that position, which was immediately seized by Stuart, who planted there a battery of 30 guns. This was the most important point on the field, for the artillery there commanded Chancellorsville and completely enfiladed the whole Union centre. As the morning fog lifted, Stuart moved to attack Sickles; the attack was hotly made and fiercely repelled. At length Sickles's ammunition fell short, and he asked for support. His demand came at an unpropitious moment. Hooker had been leaning against a pillar at Chancellorsville; a half-spent shot from Hazle Grove struck this, and Hooker fell insensible from the concussion. There was no one to send support to Sickles, though the two corps of Reynolds and Meade, together outnumbering Stuart's whole force, were wholly disengaged. Half of either of these would have been enough to insure victory; for, Stuart's attack repelled, the remainder of Hooker's

disengaged force sweeping around would have enveloped the broken corps. They could not have carried off a gun, or got away except by creeping in squads through the forest. This seems to have been Hooker's plan; but if so, no attempt was made to carry it out. Sickles, having exhausted his ammunition, sent his now useless artillery to the rear, and fell back a little to a line which he would hold by the bayonet. To his surprise he was not at once followed, and looking to his front, the enemy seemed to be broken up and defeated. Just at this moment French, with a single division, had struck Stuart's left and forced it back for a space. This was the only offensive movement made on that day by any part of Hooker's force. Stuart then rallied his whole force, and in turn repelled French. All this time Lee, with the divisions of Anderson and McLaws, had assailed the Union centre, which Slocum was holding under the enfilading fire from the 30 guns at Hazle Grove, but always edging to the right to unite with Stuart. This junction was effected at 10 o'clock, when the battle there still hung in even scale. Both sides had suffered severely. Stuart, out of the 29,000 which he had in the morning, had lost 6,000 killed and wounded, and 1,500 prisoners; Sickles and French had lost 5,000 out of 22,000. The united confederate force, about 42,000 strong after its losses, converged toward Chancellorsville. In their way stood Sickles, French, and Slocum, with 10,000 less, while not two miles distant on either hand were Reynolds, Meade, and Howard, with 42,000, not a regiment of which moved at this extreme moment toward the scene of conflict. The stress of the combined attack fell upon Sickles. Five times the assault was repelled; then all at once the whole Union line melted away, Sickles's corps first yielding the position. Couch had by this time assumed some sort of command, and in obedience to his orders the whole army fell back to the position which had been marked out during the previous night. As a defensive position to be held against a superior force, it was an excellent one. It formed a sharp curve, the apex nearly a mile back of Chancellorsville, and the sides stretching to the river and covering the fords. Each flank was protected by a small stream, with densely wooded banks. The front could be approached only by a few rough roads. Lee was on the point of ordering an attack, when he received tidings that Sedgwick had carried the heights at Fredericksburg, and Early was unable to hold the new position which he had taken up. Lee sent four brigades which had suffered least, and a series of sharp conflicts ensued, neither side gaining any important advantage. Night coming on, both armies slept upon the field.—No army ever stood in greater peril than did that of the confederates on Monday morning. All counted, it numbered less than 50,000 effective men. Stuart and Anderson at Chancellorsville, with 30,000, confronted Hooker

with 70,000; six miles to the east was McLaws with 10,000; three miles southward was Early with 9,000. Sedgwick had lost heavily, but he still had as many as McLaws and Early together. It was hardly possible that Hooker would not discover the situation, and either attack Stuart with more than two-fold numbers, or, leaving enough to hold him in check, fall upon McLaws, who would thus be crushed between two superior forces. Lee's only hope lay in dislodging Sedgwick, so he still further weakened Stuart by detaching Anderson with 10,000 men to the support of McLaws and Early, who had now effected a junction. The whole force, 27,000 strong, was at noon directed against Sedgwick, who with 18,000 assumed a defensive position. There was some skirmishing during the afternoon, but no serious action took place till 6 o'clock, when Anderson forced Sedgwick's right, under Howe, back to a strong position near the Rappahannock. Hooker meanwhile had sent contradictory orders to Sedgwick. In the morning he was told to recross the Rappahannock, if he thought best; at 11 o'clock he was directed to remain where he was. During the night he was again told to cross; a few minutes later an order countermanding this was sent; but it was not received until the former one had been obeyed, and it was too late to return, for the enemy had taken a position which commanded the bridge. But during the night Hooker had made up his mind to abandon his own position, and threw up new intrenchments to cover the bridges. Lee moved toward these, apparently intending to assault. But on Tuesday afternoon a fierce storm arose. The river rose rapidly, submerging the approaches to the bridges; one of these was taken down to piece out the other, and over this the Union army retreated during the night without being perceived. An analysis of the official reports on both sides shows that the Union loss in this series of actions was about 17,000, of which there were 12,000 killed and wounded and 5,000 missing; that of the confederates about 13,000, of which 10,300 were killed and wounded, and 2,700 missing. Of the Union loss in killed and wounded, about 7,000 were in the two corps of Sickles and Sedgwick; 4,400 in those of Slocum, Couch, and Howard; and only 600 in those of Meade and Reynolds. Of the missing, 2,000 were from the corps of Howard, which numbered only 11,000. Of the confederate killed and wounded, 6,800 were in the three divisions under Stuart, which originally numbered 30,000. Hooker himself said that he had more men than he could use; that he "had fought no battle," because he could not get his men into position to do so; and that he had failed in the enterprise which had been so brilliantly begun from causes "of a character not to be foreseen or prevented by any human sagacity or resources."—The cavalry expedition under Stoneman was equally abortive. The main body went to within 30

m. N. W. of Richmond, where it was separated into six. One struck the Jantes River canal, and made an ineffectual attempt to destroy the aqueduct across the Rivanna river; one rode to within two miles of Richmond, passing clear through the outer defences, and destroying a railroad station; four others tore up a few rails on the Fredericksburg railroad, which was the main purpose of the expedition, but doing so little injury that in three days the trains were again running. The scattered bodies at length made their way back, crossing the Rappahannock May 8.

CHANCERY. By this term is designated the English system of equity, which in a modified form has been introduced into the United States. The name, according to Coke, was derived *a cancellando*, because it was the office of the chancellor to cancel letters patent of the king which had been improvidently issued. Others, as Spelman and Cowell, suppose that it originated *a cancellis*, that is, lattice work, by which the crowd was shut off, an etymology which is supported by the analogous case of the title of the legal profession in England and this country, which is taken from the bar or railing by which practising lawyers were enclosed and separated from other attendants in court. The system which the name designates is as peculiar as its title. There are several theories as to the mode in which this branch of jurisprudence has been developed. One is that it was a usurpation by the chancellors, who were at an early period ecclesiastics, and hostile to the spirit of the common law. This was maintained by Sir Edward Coke, who while chief justice of the king's bench vigorously resisted the attempt of the lord chancellor Ellesmere to give relief against a judgment in the king's bench, which had been notoriously obtained by fraud. The parties and their solicitors and counsel were indicted for questioning the judgment; but the matter having been brought before the king, he decided in favor of the courts of equity, but putting his decision merely upon an arbitrary discretion, which he claimed as his prerogative. The jurisdiction of actions by the court of chancery took its rise from a device of ecclesiastical chancellors to evade the statutes of mortmain, that is to say, statutes prohibiting the grant of lands to religious houses. Instead of a grant of the lands directly to the parties thus disabled to take, the practice was introduced of making a grant to a person who was under no disability, but for the use of religious corporations or persons; and in chancery it was held that the use was binding in conscience, and could be enforced. It was for the purpose of getting jurisdiction of this class of cases that John Waltham, chancellor of Richard II., adopted the *subpena*, which has ever since been the process for commencing a suit in equity. To understand the nature of this innovation, it is necessary to bear in mind that all writs for the commencement of suits in the different courts,

though issued from the office of the chancellor, which was called *officina justitiæ*, were returnable not to the office from which issued, but to the courts where such suits were to be prosecuted. But the chancellor claimed to have authority from something contained in one of the statutes to compel parties to appear in chancery and answer in respect to a use. So far there is some color for the charge of usurpation of authority for ecclesiastical advantage; but when by act of parliament, passed shortly afterward, uses were made subject to the statutes of mortmain the same as the lands themselves, the doctrine of the court was found to be beneficial otherwise as a relief from restraints upon the alienation of property which had long existed. In the reigns of Henry IV. and V. the commons attempted unsuccessfully to suppress the writ of *subpœna*, the object of which was to take away the jurisdiction of the court of chancery; and in the reign of Edward IV. it had become the regular practice of the court to entertain actions commenced by that process. The statute of uses, 27 Henry VIII., by which uses were executed, that is to say, transferred into possession, seemed likely to oust the chancellor of his new jurisdiction, as the courts of common law thereupon took cognizance of a use as being the real ownership of land; but by a narrow construction of the law, by which only one use was recognized, the court of chancery was enabled to regain its power. Thus a conveyance to A, for the use of B, in trust for C, was held to be a use executed in B, and the trust for C remained and might be enforced in equity. Gradually the jurisdiction of the court was extended to a great variety of other cases, some of which were cognizable by common law courts. For the most part, however, its province was to give relief when the forms or rules of the common law could give none. Common instances of this were afforded in the case of penalties and forfeitures. At common law, the penalty of a bond was deemed the debt upon non-performance of the condition, and judgment was recovered accordingly; but in chancery the amount really due was considered to be the debt, and on tender thereof with costs of suit at any time before judgment a stay of proceedings was granted. So as to mortgage: at common law the land was forfeited upon non-payment of the debt when due; but in chancery relief was given upon subsequent payment or tender of the real debt. The same doctrine was extended to pledges, and to other personal contracts subject to a penalty or involving a forfeiture. In many of these cases the rules of law gradually conformed to equitable principles; as for instance, a judgment upon a bond, although nominally for the penalty, could be enforced only for the amount really due; and so mortgaged lands could not be retained after tender of the real debt, and this led to the process of filing a bill in chancery by the mortgagee in order to

acquire the absolute title. In general, however, all courts, chancery included, must give the same effect to positive laws, and must be subject to the same rules of interpretation, and there might be cases of extreme hardship in which equity could afford no relief whatever. In the exercise of its original jurisdiction chancery gave relief against fraud, accident, or mistake in contracts, and for this purpose might set aside written instruments, or reform them to make them conform to the real agreement of the parties; might take accounts in partnership or other mutual dealings which were too complex to be properly tried by jury; might compel the specific performance of contracts for the conveyance of lands, and in a very few other cases where the recovery of damages would be an inadequate remedy; might compel the execution of trusts, either express or implied, and exercise a general supervision over charities. The chancellor had also committed to him the general custody of infants, idiots, and lunatics, and appointed guardians of their persons and estates, to act under the direction of the court. One of the most important branches of its jurisdiction was the issuing of injunctions to stay proceedings in other courts where they were being taken against equity, to stay waste, to restrain infringements of patents or copyrights, to prevent nuisances, to enjoin the negotiation of bills, &c., where the party would be deprived of a remedy thereby, and generally to prevent irremediable injury. In many cases it aided the courts of law, by compelling parties to suits in them to make discovery of facts, by perpetuating testimony otherwise in danger of being lost, and sometimes by enjoining the setting up of an inequitable defence. Proceedings in equity have differed from those at law principally in three particulars: 1, in the proofs, the complainant being at liberty to compel the defendant to give evidence by his answer; 2, in the mode of trial, which formerly was by taking the written depositions of witnesses, upon which the judge passed without the aid of a jury; and 3, in the mode of relief, which at law was usually the award of damages, while in equity a specific execution of contracts might, as we have seen, in some cases be compelled, and in others damages might be anticipated and enjoined.—Equitable remedies have until recently been administered in England by the lord high chancellor, assisted by three vice chancellors and the master of the rolls, and also by two lords justices sitting with the chancellor as a court of appeal. Formerly the court of exchequer also had equitable jurisdiction. The court of chancery was formerly the subject of very serious complaints because of its delays and expenses, but these were obviated to a considerable extent by the abolition of the office of master in chancery, and by giving the court authority to order the testimony to be taken in open court, and in its discretion to summon a jury for the trial of disputed ques-

tions of fact. Even these, however, have not satisfied the demands of reform. For more than a quarter of a century a sentiment has been growing and strengthening in England that the distinctions between law and equity, in their principles as well as in their administration, were unnecessary, illogical, expensive, and vexatious; and this has culminated at last in the act of Aug. 5, 1873, matured and supported by the lord chancellor himself, which consolidates all the superior courts of England, including the court of chancery, into one supreme court of England, which is to be presided over by the lord chancellor, and, without distinguishing between law and equity, to administer justice on equitable principles. The old forms of pleading are abolished; the summons by which the suit is commenced is indorsed with a statement of the nature of the claim made or the relief or remedy sought, the defendant files a statement of his defence, and the plaintiff replies if a reply is needful. Causes will be tried before one or more of the judges, sitting with or without assessors or a jury, or may be sent to a referee for hearing. (See COURT.)—In the jurisprudence of nearly all the United States equity law is administered by the same judges who sit in law cases, but under the forms prevailing in England before the recent changes. Some of the individual states have never had any distinct equity system, but in these equitable remedies have to some extent been administered under legal forms. In others there has been a separate court of equity; in others still equity law has been administered by the law judges as under the federal system. New York led off in 1848 with a code which abolished all the forms of action, and substituted a simple statement of the party's case in a complaint for the former declaration at law and bill in equity; thereby seeking to abolish the distinction between law and equity. Several other states have followed this example.

CHANDERNAGORE, a French colony in India, on the Hoogly, 17 m. N. of Calcutta; pop. about 29,000, of whom a few hundred are Europeans and the rest Hindoos. The settlement includes, besides the town, an island in the river and several villages, with an aggregate population of about 40,000. The quays of the town are fine, and the streets are in good condition; yet it presents a dilapidated appearance, though there are vestiges of former splendor and many Hindoo temples. The main occupation of the inhabitants is raising cattle. The principal export is opium.—This settlement was ceded in 1688 to the French East India company, and flourished under Duplex. The English captured the town in 1757, and dismantled the fortifications. Restored to France in 1763, it again became an English possession in 1793. In 1816 it was returned to France, but has lost almost all its former importance.

CHANDLER, Richard, an English archæologist, born at Elson, Hampshire, in 1738, died at

Tilehurst, Berkshire, Feb. 9, 1810. He studied at Winchester and Oxford, held various livings in Hants, travelled extensively in Asia Minor, Greece, and other countries, and in 1800 was appointed rector at Tilehurst, where he spent the rest of his life. His works include a celebrated edition, undertaken under the auspices of the Oxford university, of the *Marmora Oxoniensia* (1763); "The Ionian Antiquities, or Ruins of Magnificent and Famous Buildings in Ionia," published jointly with the artists Revett and Pars, his fellow travellers, as the result of their explorations under the auspices of the dilettanti society (2 vols. fol., London, 1769-1800); and *Inscriptiones Antiquae, &c.* (Oxford, 1774). He left a life of William Waynflete, bishop of Winchester, and founder of Magdalen college, which was published in 1811. His most remarkable productions are his "Travels in Asia Minor" (Oxford, 1775), and in Greece (1776), which proved very useful to Barthélemy in the preparation of his *Anacharsis*. Servois and Barbié du Bocage corrected some of the errors of these works in their French translation (3 vols., Riom, 1806). A new English edition, with notes by Revett, was published by the Rev. R. Churton, with a biography of the author (2 vols. 8vo, 1835). Chandler also prepared, in vindication of Homer's descriptions, a "History of Ilium, or Troy," as a continuation of these works (first part, London, 1802).

CHANDLER, Samuel, an English theologian, born at Hungerford, Berkshire, in 1693, died in London, May 8, 1766. He was the son of a non-conformist clergyman, and had for fellow pupils Joseph Butler, author of the "Analogy," and Thomas Secker, afterward archbishop of Canterbury. He completed his studies in Leyden, and became Presbyterian minister at Peckham. The South sea bubble of 1720 swallowing up his wife's fortune, he embarked in the book trade in London, while continuing to preach, and was selected with Dr. Lardner as an evening lecturer to a dissenting congregation in the Old Jewry, of which he was chosen pastor in 1726, and remained so till his death, 40 years after. He received the degree of D. D. from the universities of Edinburgh and Glasgow, and was a member of the royal and antiquarian societies. In 1760 he delivered a sermon on the death of George II., in which that monarch was likened to David; whereupon a pamphlet appeared, embodying Bayle's disparaging estimate of the Hebrew king. Chandler replied to the pamphlet, and was thus led to write his "Critical History of David" (2 vols., London, 1766), which is his most elaborate work. He wrote "A Vindication of the Christian Religion" (1725), "A History of Persecution" (1736), and several volumes of commentaries on different books of the Bible. A collection of his sermons was published after his death (4 vols. 8vo, 1768).

CHANDLER, Thomas Bradbury, D. D., an American clergyman, born at Woodstock, Conn.,

April 26, 1726, died at Elizabethtown, N. J., June 17, 1790. He graduated at Yale college in 1745, in 1747 was appointed catechist and lay reader in St. John's church, Elizabethtown, N. J., and in 1751 went to England for the purpose of receiving episcopal ordination. Upon his return he was made rector of St. John's church, and in 1766 received the degree of D. D. from the university of Oxford. In the discussions which preceded the war of the revolution, he rendered himself unpopular by advocating the claims of the British government. Partly on this account, and partly to obtain medical advice, he went to England in 1775, where he remained 10 years, occupying himself in study and writing, and receiving a salary of £50 from the society for the propagation of the gospel, and an annuity of £200 from the British government, which after his death conferred a pension upon his widow. On the conclusion of peace in 1783, his congregation requested him to resume his position as their rector. He returned to Elizabethtown in 1785, but in exceedingly ill health. A cancerous affection had developed itself upon his face, which greatly disfigured him, and in consequence he declined the bishopric of Nova Scotia, which had been offered him while in England. After his return to America he never attempted to perform any public service, but occasionally walked out with his face covered by a handkerchief. The vestry did not think proper, however, to appoint another rector, and in compliance with their request he consented to retain the station during his life. He was a zealous defender of Episcopacy, and in 1767 published "An Appeal to the Public in behalf of the Church of England in America." Soon after the appearance of this work it was attacked simultaneously from various quarters, and among others by Dr. Chauncy of Boston, who published an answer in behalf of the non-Episcopal churches. To this Chandler replied in 1769; Chauncy rejoined, and in 1771 Chandler responded in a third pamphlet.

CHANDOS, Sir John, an English soldier, born at Radborne early in the 14th century, fell in battle at Lussac, Poitou, in 1369. He was the elder son of Sir Edward Chandos, and one of the original knights of the garter. He distinguished himself at Crécy and Poitiers, and received from Edward III., besides other favors, a barony and the title of vice chamberlain. The victory at Auray in 1364, in favor of the earl of Montfort, son-in-law of Edward III., as duke of Brittany, against Charles de Blois, was chiefly due to his valor. He procured the liberation of his antagonist Bertrand du Guesclin, won renown on various other occasions, and became constable of Aquitaine and seneschal of Poitou. The king of France exclaimed on his death that Chandos was the only warrior who could have made peace between him and Edward. He was buried at Mortemer, near Neufchâtel. Froissart and other historians praise his virtues and heroism.

CHANGARNIER, Nicolas Anne Théodule, a French general, born at Autun, April 26, 1793. He was educated at the military school of St. Cyr, served as a lieutenant in the campaign of 1823 in Spain, and finally entered the royal guards. After the revolution of 1830 he went to Africa, where he soon distinguished himself, and became brigadier general in 1840, and general of division in 1843. In 1847 the duke d'Aumale, being governor general of Algeria, caused Changarnier to be put in command of the district of Algiers, and on the revolution of February resigned the governorship into his hands. Gen. Cavaignac having been appointed to this office by the republican government, Changarnier repaired to Paris, and was appointed ambassador to Berlin, but did not leave Paris, his services being required there to protect the national assembly. When Cavaignac became minister of war, Changarnier was appointed his successor as governor general of Algeria, which post he held for five months. Having been elected to the national assembly, he returned to Paris, and was invested with the command of the national guards. When Louis Napoleon became president, Changarnier was appointed commander of the regular troops, known as the army of Paris. He prevented outbreaks on Jan. 29 and June 13, 1849, and supported Louis Napoleon for a considerable time, exciting the distrust of the republicans. But he afterward strenuously opposed the president's measures, and lost his command on Jan. 9, 1851. The project of the assembly to place him in command of a force for its special protection against arbitrary proceedings having fallen to the ground, Changarnier, after declaring that Louis Napoleon would not find even one single soldier to assist him in a *coup d'état*, was powerless to prevent that event, and was arrested Dec. 2, 1851, and detained at Mazas for about a month, when he was banished from France, and took up his residence at Mechlin, Belgium. In 1859 he availed himself of the general amnesty to return to France. On the outbreak of the Franco-German war, Marshal Lebœuf, the minister of war, declined to avail himself of his services; but in August the emperor invited him to come to Metz, where he remained with Bazaine, who employed him in initiatory negotiations with Prince Frederick Charles, which resulted on Oct. 27 in the capitulation of the French army. Changarnier was a prisoner of war in Germany until the conclusion of the armistice in January, 1871, after which he returned to Paris. He was elected to the national assembly by the departments of Gironde, Le Nord, and Somme, and took his seat for the last named district.

CHANG-CHOO-FOO, a city of China, in the province of Fokien, on the river Chang, 30 m. W. of Amoy; lat. 24° 35' N., lon. 117° 50' E.; pop. estimated at nearly 1,000,000. It lies in a picturesque valley, and is surrounded by a wall about 4½ m. in circumference, in which are four principal gates at the N., E.,

S., and W., not only forming means of access for roads into the city, but also admitting canals. The houses are very well built, but the streets are narrow, their width seldom exceeding 12 ft. A remarkable bridge crosses the river opposite the town; it is built on irregularly piled stone piers, of which there are about 30, nearly 30 ft. apart. The roadway, about 20 ft. above the water, is made of large stone blocks resting upon wooden beams. Chang-choo-foo is the centre of the silk manufacture of the province, and its trade both with the interior and with foreign ports is very active. Large tile and sugar factories give commercial importance to the suburbs.

CHANG-CHOW, or **Chang-choo**, a city of China, in the province of Kiang-soo, on the E. bank of the imperial canal, about 100 m. N. W. of Shanghai; lat. 31° 55' N., lon. 119° 43' E. It is surrounded by a wall 25 ft. high, and is otherwise well fortified. Several small canals connect it with the Tai-ho or great lake, and its commerce was formerly very extensive. Chang-chow is chiefly celebrated for the events of which it was the scene during the last decade of the Taiping rebellion. From 1860 to 1864 the place formed one of the chief strongholds of the rebels, resisting successfully all the attacks made upon it by the imperial troops. In the spring of the latter year the English Major Gordon, commanding 70,000 Chinese instructed in foreign tactics, laid siege to it; and on May 11 the city was carried by assault, after a conflict which ended in a massacre. Several thousand Cantonese troops, forming part of the garrison, were slaughtered after the capture; but about 20,000 natives of the province of Kiang-su, who had been pressed into the rebel service, were spared.

CHANNEL ISLANDS, a group of islands belonging to Great Britain, in the English channel, between lat. 49° and 49° 50' N., and lon. 2° and 2° 45' W., off the N. W. coast of France, between Normandy and Brittany; shortest distance from the French coast, 15 m., and from the English coast at Southampton, 115 m.; area, about 75 sq. m.; pop. in 1871, 90,563. The islands are: Jersey, pop. 56,627; Guernsey, with the islets Herm and Jethou, 30,667; Alderney, 2,718; and Sark, 551. The picturesque situation, the moderate cost of living, the mild climate, and the lightness of the taxes render these islands a favorite resort, and they are easily accessible by steamers from Southampton and Weymouth. The vernacular is the old Norman French, but the modern French is now used in the law courts. English is spoken in the towns. The soil is fertile, but owing to the minute subdivision of the land, agriculture is in a rather backward state. Horticulture and floriculture are flourishing. The principal manure is seaweed, which is also largely used for the production of kelp and iodine. The breed of cattle known as Alderneys are noted for their small size, symmetry, and excellence as milkers. Cattle raising, the

dairy, and fishing are the principal occupations of the inhabitants. The exports to the United Kingdom, comprising cider, wine, apples, and potatoes, amounted in 1870 to £457,389; and the imports, mainly manufactures, wheat, flour, sugar, and coffee, to £916,138. Near Ortach passage, about 6 m. W. of Alderney, are the Caskets, a dangerous cluster of rocks, where Prince William, only son of Henry I., perished in 1120; and the Victory with 1,100 men was lost here in 1744. Many lighthouses have been built off the islands within a few years.—These islands were known to the Romans, and are the only portions of the former duchy of Normandy now belonging to Great Britain, to which they have been attached since the conquest. They still retain a certain independent status, the government being administered by states, the members of which are partly named by the crown, partly chosen by the people, while others sit *ex officio*. Each of the principal islands has a military lieutenant governor, who sits in the states as representative of the crown. The high sheriff is variously called the *vicomte* and the *prévôt*. The royal court in each island consists of the bailiff or judge and the jurats or magistrates. There is no trial by jury, but an appeal may be made to the sovereign in council. The fortifications of the islands cost £500,000 annually, while the revenue is only about £20,000.

CHANNING, Edward Tyrrel, LL. D., an American scholar, born at Newport, R. I., Dec. 12, 1790, died at Cambridge, Mass., Feb. 8, 1856. He entered Harvard college in 1804, but left in his junior year in consequence of a dispute between the students and the faculty, and did not receive his degree until some years later. He studied law in Boston with his elder brother, Francis Dana Channing, and was admitted to the bar, but devoted himself to literature. In 1817-19 he was editor of "The North American Review," and afterward Boylston professor of rhetoric and oratory in Harvard college till 1851. He was a frequent contributor to the "Review" almost to the time of his death, and did much to elevate the standard of culture in his collegiate department. In 1856 a volume containing 20 of his lectures was published, with a memoir by Richard H. Dana, jr.

CHANNING, Walter, an American physician, brother of the preceding, born at Newport, R. I., April 15, 1786. He entered Harvard college in 1804, but left in his junior year on account of the college dispute of 1807. He studied medicine in Boston and Philadelphia, received the degree of M. D. from the university of Pennsylvania, afterward studied at the university of Edinburgh, and at Guy's and St. Thomas's hospitals in London, and began practice in Boston in 1812. The same year he was appointed lecturer, and in 1815 professor, of obstetrics and medical jurisprudence in Harvard university, which office he filled until his resignation in 1854. In 1821 he became as-

sistant of Dr. James Jackson as physician of the newly established Massachusetts general hospital, and labored there for nearly 20 years. He has been a frequent contributor to medical and literary periodicals, besides publishing "Etherization in Childbirth," illustrated by 581 cases (Boston, 1848); a volume of "Miscellaneous Poems" (1851); and "A Physician's Vacation, or a Summer in Europe" (1856). The treatise on "Etherization in Childbirth" attracted great attention both in Europe and America, and had a marked effect on the state of that branch of science. Subsequently he published "Professional Reminiscences of Foreign Travel," "New and Old," and "Reformation of Medical Science" (1857).

CHANNING, William Ellery, D. D., an American clergyman and author, brother of the preceding, born at Newport, R. I., April 7, 1780, died at Bennington, Vt., Oct. 2, 1842. His physical organization was at once delicate and vigorous; his appearance was grave and reflective; his mind was early occupied by religious and poetic conceptions, and he sometimes startled his associates by the vehemence with which he would repress any injustice that was attempted. The lessons of his mother had developed his religious sensibility, and the doctrinal conversations then in vogue had turned his attention to theology, when at the age of 12 he was sent to New London, Conn., to prepare for college. His father soon afterward died, and to the impression of the funeral and the influence of a revival which then swept over New England he attributed the commencement of his decidedly religious life. Esteemed by his friends for diligence and scholarship, for fine powers and pure habits, he entered the freshman class of Harvard college in 1794. In no single study superior to all of his classmates, he surpassed them all in versatility of talent and the wide range of his accomplishments, and especially in his power of written composition. As his character matured, he devoted himself more and more intently to aspirations after moral greatness. He studied the Stoics, and was profoundly moved by the stern purity which they taught. In reading Hutcheson's essays on "Beauty and Virtue," in which virtue is defined as self-devotion to the absolute good, and the universe described as a system of progressive order and beauty in which there are infinite possibilities of spiritual destiny, he attained that sublime view of the dignity of human nature which he ever after maintained. The work of Ferguson on "Civil Society" also concentrated his energies on the thought of social progress. The study of Shakespeare gave him a powerful intellectual impulse, and through life one of his chief intellectual pleasures was furnished by recitations from his plays. The interest which he took in prevalent social agitations appears from the subject of the oration, "The Present Age," which he delivered at the graduation of his class. Having selected the profession of divinity, he spent

18 months after leaving college as tutor in a private family at Richmond, Va., where his time was passed in agreeable social relations and in study, chiefly of political and theological subjects. His health suffered severely from his anxious examination of speculative doctrines, and in 1800 he returned to Newport to continue his studies. There he used to alternate between the public library and the seashore, on which he afterward affirmed that he had passed his hardest spiritual struggles. In 1801 he removed to Cambridge, having been elected regent in the university, and devoted himself to theological study and spiritual discipline. He was intimately connected with Dr. Samuel Hopkins, the disciple of Jonathan Edwards, whom he warmly esteemed; and when in 1802 he received from the Cambridge association the usual approbation to preach, it was supposed by many of the ministers that he would enlist on the side of extreme orthodoxy. Yet, as he subsequently stated, he was at this time an Arian, though tinged with ethical opinions derived from Dr. Hopkins. His preaching at once attracted attention for its fervor and solemnity, and both the Brattle street and Federal street societies in Boston sought to obtain him for their pastor. Diffident both of his health and abilities, he chose to settle over the smaller society in Federal street, and was ordained June 1, 1803. His congregation increased with his reputation for eloquence and devotion, till in 1809 the old church was taken down to give place to one larger. His whole spiritual energy became concentrated in his labors as pastor, in sermons so exhausting that he was nearly prostrated at their close, in attending prayer meetings and Sunday schools, and in ministering to the sick and mourning. By the custom of exchanging with other clergymen he became widely known throughout New England, and it was said of him and his friend, the younger Buckminster, that they had introduced a new era in preaching. When the disagreement in doctrine between the "liberal" and the "orthodox" Congregationalists burst forth into the Unitarian controversy, Dr. Channing was the acknowledged head of the liberal party, and took an active part in its defence. Opposed to the Calvinistic scheme and the doctrine of the Trinity, he was even more at variance with the views of Priestley and Belsham. He blended in his system views which have generally been deemed discordant; and without checking himself by dialectic difficulties, he threw over his complex theology the charms of imagination and sentiment, and linked it with schemes of moral and social reform. During the period of most vehement debate his pure and earnest character won the constant admiration of his opponents. In 1814 he married, and soon after obtained some acquaintance with the master minds of Germany. From Kant's doctrine of the reason he derived deeper reverence for the essential powers of man; by Schelling's intimations of the divine

life everywhere manifested, he was made more devoutly conscious of the universal agency of God; and he was especially delighted with the heroic stoicism of Fichte and his assertion of the grandeur of the human will. But for his greatest pleasure and best discipline he was now indebted to Wordsworth, whom he esteemed next to Shakespeare. From this time he began to engage more actively in political and philanthropic movements. He delivered, June 15, 1814, a discourse on the overthrow of Napoleon and the "goodness of God in delivering the Christian world from military despotism." He early gave his sympathy and support to the peace movement in this country; and in 1816 he preached a discourse on war before the convention of the Congregational ministers of Massachusetts, which was printed and widely circulated, and prepared the way for the formation of peace societies in several of the states. Temperance, reform in penitentiary discipline and punishments, missions, and Bible distribution all received his encouragement. His church was always thronged when he preached, and by various public discourses, among which were sermons occasioned by political crises, a sermon on the Unitarian controversy delivered at Baltimore in 1819, and his Dudleian lecture on the "Evidences of Christianity," delivered at Cambridge in 1821, his celebrity was extended throughout the country. In 1822 he made a European tour, saw Wordsworth and Coleridge in England, the latter of whom wrote of him, "He has the love of wisdom and the wisdom of love," and visited France, Switzerland, and Italy. On his return he resumed his pastoral labors with more than his former energy, till in 1824 he received as colleague the Rev. Ezra Stiles Gannett; and from this time his efforts were more in the general field of literature and reform. His remarks on the character and writings of Milton, his two articles on the life and character of Bonaparte, and an article on Fénelon, published between 1826 and 1829, attained a very wide celebrity, and brought him into correspondence with several of the most eminent literary persons in England and America. His writings are most characteristic and effective when treating questions of Christian philanthropy and social reform. In behalf of peace, temperance, education, and freedom, he repeatedly came before the public, and he examined with sympathizing respect and anxious scrutiny every movement which promised more happy social relations. Without accepting absolutely the doctrine of non-resistance, he remonstrated against war, reviewing its crimes and miseries, in 1835, when there was danger of a rupture with France, and in 1839, when there was a prospect of conflict with Great Britain. The wide scope which he gave to education is seen in some of the most valuable of his lectures, especially that on "Self-Culture," delivered in 1839, and the series on the "Elevation of the Laboring Classes," in 1840. His attention was specially turned to the subject

of slavery by a winter's residence on the island of Santa Cruz in 1830. His first efforts were to arouse the moral feeling against slavery, and it was not till 1837 that he deemed special political action needful. In that year, by addressing a public meeting in Faneuil Hall, he became closely identified before the public with the abolition movement, into which he sought to infuse his own spirit of calmness and candor. His work on "Slavery," published in 1841, had a wide circulation, and the last public act of his life was to deliver an address at Lenox, Mass., Aug. 1, 1842, on the anniversary of the emancipation in the West Indies. During the latter years of his life he resided in winter in Boston and in summer in Newport, and his death was caused by an attack of typhus fever while pursuing a mountain excursion. Dr. Channing belonged to the poetic order of philosophic minds. His words as well as his opinions were usually chosen from among those which express the sunny, hopeful, and possible view of things. He was buried at Mount Auburn, where a monument designed by his friend Washington Allston was dedicated to his memory.—The most complete edition of his works was published in Boston in 1848, in 6 vols. 12mo, and between 1870 and 1872 200,000 copies were issued by the American Unitarian association. In England a selection of his works appeared in 1849 under the title, "Beauties of Channing." Many of his essays have been translated into German at various times, and a more complete selection from his works was translated by Sydow and Schulze (15 vols., Berlin, 1850-'53). His nephew, the Rev. William Henry Channing, prepared "Memoirs of William Ellery Channing, with Extracts from his Correspondence and Manuscripts" (3 vols., Boston, 1848). Édouard Laboulaye published *Œuvres sociales de W. E. Channing, précédées d'un essai sur sa vie et ses doctrines* (Paris, 1854); and the translations, *De l'esclavage* (1855), and *Traité religieux*, also preceded by introductions (1857), were favorably reviewed in the leading French periodicals. In 1857 appeared, from the pen of an English lady, a French work founded upon the "Memoirs" by the Rev. W. H. Channing, and entitled *Channing, sa vie et ses œuvres*, with a preface by M. Charles de Rémusat, of which an enlarged edition was published in 1861. "The Perfect Life, in Twelve Discourses," edited from Channing's MS. by his nephew and biographer, was published in 1873. The French academy of moral and political sciences offered a prize for the best essay or *étude* on Channing, for which in 1873 there were three competitors.

CHANNING, William Ellery, an American author, son of Dr. Walter Channing, born in Boston, June 10, 1818. He was sent in his 8th year to the Round Hill school at Northampton, and afterward to the Boston Latin school, where Charles Sumner was one of his instructors. On leaving the Latin school he entered Harvard college, but did not remain there suf-

ficiently long to graduate. In 1839 he removed to Illinois, and lived for a year and a half in a log hut built by himself on a prairie. In 1840 he went to Cincinnati, and was for a short time connected with the "Gazette." In 1842 he returned to Massachusetts, and having soon after married a sister of Margaret Fuller, established his home in Concord, where with short intervals of absence he has since continued to reside. In 1844-'5 he was employed on the editorial staff of the New York "Tribune." In 1846 he made a brief visit to Europe. In 1855-'6 he was one of the editors of the New Bedford "Mercury," and lived for a while in that city. Mr. Channing began at the age of 18 to contribute verses to the Boston "Journal," in which he also published a series of essays on Shakespeare. He wrote much in prose and verse for the "Dial" (1841-'4), including an unfinished romance entitled "The Youth of the Poet and Painter." In 1843 he published a volume of poems; a second volume in 1847; a third, "The Woodman," in 1849; and two other volumes of verse, "Near Home" (1858), and "The Wanderer" (1872). He has also published two prose volumes, "Conversations in Rome" (1847), and "Thoreau, the Poet-Naturalist" (1873).

CHANNING, William Henry, an American clergyman, cousin of the preceding, born in Boston, May 25, 1810. His father, Francis Dana Channing, died when he was very young. His early education was received at an academy in Lancaster, Mass., and at the Boston Latin school. He graduated at Harvard college in 1829, and at the Cambridge divinity school in 1833, and was ordained at Cincinnati in 1835. He has been pastor of several religious societies in America, and in 1857 succeeded James Martineau as minister of the Hope street Unitarian chapel, Liverpool, England. He returned home soon after the beginning of the civil war, and was settled for a time as pastor of the Unitarian church in Washington. For many years he took a conspicuous part in the socialistic movement, editing "The Present" and "The Harbinger," and in 1848 was president of the Boston union of associationists. He has been connected with the press as editor of several journals, and as contributor to the "North American Review," the "Dial," and the "Christian Examiner." He has translated Jouffroy's "Ethics" (2 vols., Boston, 1840), and written the "Memoir of William Ellery Channing" (3 vols., Boston, 1848), "Memoirs of the Rev. James H. Perkins" (2 vols., 1851), the "Memoirs of Margaret Fuller Ossoli" (in conjunction with R. W. Emerson and J. F. Clarke, 2 vols., 1852), and a work on "The Christian Church and Social Reform." In 1869-'70 he delivered a course of lectures before the Lowell institute, Boston. In 1872 he published in London "The Perfect Life," a posthumous volume of Dr. Channing's sermons, for which he wrote a preface. At present he lives in England.

CHANT (It. *canto fermo*; Fr. *plein chant*), a modification of song, between air and recitative, such as is adapted to the psalms and litanies. This species of music is very ancient. St. Paul exhorts the early Christians to chant psalms and canticles. Pliny the Younger mentions that the Christians assembled at break of day to chant their hymns. The chant grew with the progress of Christianity. Pope Sylvester about 330 founded a school for its culture; and St. Ambrose arranged from the old Greek music a new description of chant, the Ambrosian, which remained in use until superseded by the chant arranged by Pope Gregory the Great, hence called the Gregorian or Roman chant, and which, somewhat modified, is in use at the present day. (See **AMBROSIAN CHANT**, and **GREGORIAN CHANT**.) Chants are properly of three kinds: the monody, sung by one voice; the antiphony, alternately by two; and the choral, by all voices.

CHANTAL, *Jeanne Françoise Frémot*, baroness de, a saint of the Roman Catholic church, born at Dijon in 1572, died at Moulins in 1641. She was the daughter of a president of the Dijon parliament, and early married Christophe de Rabutin-Chantal. Her husband was killed while hunting, and although she was only 28 years of age, she took a vow never to marry again. From this time her sole occupation and recreation was the education of her children and the care of the sick and the poor. She became acquainted with St. Francis de Sales in 1604, and placed herself entirely under his direction. He communicated to her his project for the establishment of the order of the Visitation, and she so far entered into his views that in 1610 she laid the first foundation of that order at Annecy. She established her children in life (one of whom became the father of Mme. de Sévigné), and then devoted the remainder of her days to the order, being designated as the *mère de Chantal*. At her death the order comprised 87 houses; at the close of the 17th century they numbered 150, and about 6,600 members. Her beatification took place in 1751, and she was canonized by Clement XII. in 1767. Her life and letters were published in Paris, 1779.

CHANTIBUN, or *Chan-ta-bon*, a town of Siamese Cambodia, on a small river 5 m. E. of the gulf of Siam, 140 m. S. E. of Bangkok; pop. about 30,000, chiefly Chinese. It lies at the foot of a chain of mountains. The exports include pepper, rice, gamboge, cardamoms, and dyewoods, which are shipped on small boats to Bangkok and thence sent to foreign countries.

CHANTILLY, a town of France, in the department of Oise, 24 m. N. by E. of Paris; pop. about 3,500. It abounds in natural beauties. A forest extending over nearly 7,000 acres adjoins the fine public park and pleasure grounds. Three annual horse races are held here, the spring race being the most important. The *grand château*, in which the great Condé gave splendid entertainments, was destroyed in 1793,

and only the renowned stables and the *petit château* remain. The latter, one of the most admired renaissance structures in France, reverted after the death of the last of the Condés

Dome of Stables, Chantilly.

in 1830 to the duke d'Aumale, to whom it was restored in 1872, after having been confiscated by Louis Napoleon. The town contains an English chapel. There are several large establishments for supplying lacemakers in the vicinity with patterns and materials for a peculiar kind of lace known as Chantilly.

CHANTREY, Sir *Francis*, an English sculptor, born at Norton, Derbyshire, April 7, 1781, died in London, Nov. 25, 1841. Although designed for the law, his taste led him to be apprenticed to a wood carver; and later, wishing to be more wholly an artist, he undertook modelling in clay, first in Dublin, then in Edinburgh, and lastly in London. A bust sent in 1806 to the exhibition of the royal academy interested Nollekens, a popular sculptor, through whom Chantrey was brought into notice, and soon became famous. He was made a member of the royal academy in 1818, and in 1819 of the academies of Rome and Florence, and was knighted in 1835; and as a popular sculptor of monumental figures he acquired a large fortune. His ideal works are few and unimportant, and some of the best of them are from the designs of others; he suffered moreover from disease of the heart, so that many of his works had to be finished by his assistant, Mr. Weekes; yet he gained the foremost place in this order of sculpture, and his numerous busts form a complete gallery of the most distinguished men of his time. His monumental works are the most important; the best of them being the "Sleeping Children," in Lichfield cathedral, after designs by Stothard. He enriched Westminster abbey with many sculptures, among which the fine statue of Canning is considered his masterpiece. One of his best works is the bronze statue of Pitt, in Hanover

square, London. He also made the statues of Washington, in the state house, Boston; James Watt, in the church of Aston, near Birmingham; and Bishop Heber, at Calcutta. He constructed a funeral vault for himself in the church of Norton, where he was buried; and left certain bequests to the clergyman and the poor of the place upon condition of the tomb being kept in order. He died without children or near relatives, and left his fortune, after suitable provision for his widow, for the encouragement of art. The original models of most of his works, comprising valuable portraits of his contemporaries, were presented by Lady Chantrey to Oxford university.—See his life by George Jones (London, 1850), and by John Holland (1851).

CHANZY, Antoine Eugène Alfred, a French soldier, born at Nouart, Ardennes, March 18, 1823. He enlisted in his 16th year as a cabin boy on a man-of-war. The next year he returned to school, and subsequently studied at the military academy of St. Cyr. He served in Algeria under Canrobert, and in 1859 distinguished himself in the battle of Solferino, Italy, where he became lieutenant colonel. He rejoined the service in Algeria, and in 1868 attained the rank of brigadier general. In the Franco-German war he was general of division of the 16th corps in the army of the Loire, under Aurelle de Paladines. He proposed to prevent the junction of the German armies, defeat them in detail, and march on Paris; but his plan was not adopted. During the protracted struggle before Orleans, he attacked the Germans on Dec. 1, 1870, and gained some indecisive successes in the vicinity of Patay; but the next day he was assailed by the grand duke of Mecklenburg and Gen. Von der Tann, lost ground after a bloody engagement, and was obliged to retreat on Dec. 3. The disastrous defeat of the army of the Loire was chiefly ascribed to the isolation of the 18th and 20th corps, and to Prince Frederick Charles's availing himself, by a decisive stroke, of their immobility, to mass his troops against the French centre. Chanzy was now appointed commander-in-chief of the so-called second army of the Loire, thus dividing with Bourbaki, appointed to the head of the first army, the former command of Aurelle de Paladines. He made a vigorous stand at Meung and Beaugency, in order to cover Tours; but was soon forced to abandon the line of the Loire, and after various desperate conflicts between that river and the Sarthe, he was overwhelmingly defeated before Le Mans, Jan. 12, 1871, and told the government that it was impossible to continue the war. The projects of Chanzy were regarded as brilliant and skilful, but both he and Aurelle de Paladines were obliged to follow the instructions of the political authorities. Chanzy became a member of the national assembly at Bordeaux and Versailles, and published in 1871 *La deuxième armée de la Loire* (4th ed., April,

1872), in vindication of his generalship and of the bravery of his troops. In September, 1872, he was appointed commander of the 7th army corps at Tours, and in 1873, under President MacMahon, governor general of Algeria.

CHAOS (Gr. *χάος*, from *χαλναιν*, to gape, to open widely), in classical mythology, either the empty and infinite space which existed before all things or the mixture of all the elements, the confused mass out of which the ordered creation was formed. By the poets Chaos was personified and made the most ancient of the gods, the father of Erebus and Night. The principle of the fecundity of chaos assumed several modifications in the Greek systems of philosophy. Something similar to the Greek conception of chaos is found in the Phœnician, Chaldean, and Indian cosmogonies; and Ovid's description of the genesis of the universe out of chaos has so many features in common with the Mosaic account of creation, that it has often been supposed to have been derived from it.—In natural history, *chaos* is the name given by Linnæus to animals and plants of the lowest orders, which have imperfect parts.

CHAPALA, a lake in the state of Jalisco, Mexico, bordering upon Guanajuato on the north and Michoacan on the east and southeast. It lies between lat. 20° 15' and 20° 45' N., and lon. 101° 50' and 103° 17' W., and has an area of about 1,200 sq. m., being thus the largest lake in the republic. Its depth during the floods—July and August—is 6½ fathoms, gradually diminishing in the dry season to about 5 fathoms. Its surface is interspersed with beautiful islands. The lake communicates with the Rio Grande de Santiago, to the waters of which river it is supposed to owe its formation. It abounds in excellent fish, affording a profitable occupation to numbers of the inhabitants of the adjacent country.

CHAPEL, a term originally applied to private oratories, derived from the practice of the ancient kings of France of carrying along with them on the battle field St. Martin's hat as a relic, the place in which it was kept being called *capella*, and the priest in charge of it *capellarius*. The famous *sainte chapelle du palais* in Paris was built by St. Louis, and consisted of an upper and lower chapel, which latter is in course of restoration. It suffered much during the revolution, and its relics are in Notre Dame. In the latter cathedral is the celebrated *chapelle du damné*, deriving its name from the legend that Raymond Diocrès, a friend of St. Bruno, returned to life during his funeral, and exclaimed that he was damned, which led to the saint's retirement to a cloister, and furnished the theme for Lesueur's celebrated painting. In the church of St. Victor at Marseilles there was a subterranean chapel, which women durst not enter because, according to a legend, a queen was punished with the loss of her sight for having entered it; and there are a number of chapels in Rome inaccessible

to women except at the risk of excommunication. The music of the chapels of Louis XIV. and other French sovereigns was remarkable for its beauty, and the term chapelmaster is hence often applied on the continent to leaders of orchestras. *Chapelles ardentes* were laid out with great splendor for the celebration of the funerals of French sovereigns, and date from the earliest Christian ages. One of the most magnificent of the kind was that built for receiving the ashes of Napoleon I. when they were brought in 1840 to Paris from St. Helena. There are at this day five categories of chapels in France: *simples* or *communales*, *vicariats de secours*, *domestiques*, and those inside of churches. In Rome, besides the renowned Sistine chapel, there is that of San Andrea della Valle, which is said to have been built on the spot of St. Sebastian's martyrdom. The chapel dedicated to St. Clement is associated with a legend that it was built by angels, and suddenly appeared on the spot, from which the sea had just retreated, upon the drowning of the saint by order of Trajan. In England, at the present day, dissenting places of worship are generally called chapels, and there are parochial chapels distinct from the parish church; while on the continent of Europe Anglican churches, being generally small, are designated as chapels. Chapels of ease exist in large English parishes for the accommodation of neighboring worshippers; and there are private chapels in many residences of noble families in England, as well as at many foreign legations in various countries. In Roman Catholic churches chapels are often set aside and dedicated to services in honor of particular saints. The knights of the chapel, or poor knights of Windsor, were designated in the will of Henry VIII. for attending royal funerals. Their number has been increased from 13 to 26. They are under the authority of the canons of Windsor, and receive pensions from the order of the garter. They wear the arms of St. George and a red or blue cloak.—The famous chapels of Italy and other countries are mentioned in the articles upon the respective localities to which they belong.

CHAPELAIN, Jean, a French poet, born in Paris, Dec. 4, 1595, died there, Feb. 22, 1674. His father wished him to adopt his own profession of notary; but his mother, who had known Ronsard, roused his literary ambition, and he studied foreign languages and also medicine. He became a teacher of Spanish, and afterward was for 17 years in the service of the family of M. de la Trousse, grand provost of France, first as tutor and afterward as steward. After the arrival in Paris of Marini, the Italian poet, he wrote a preface for his *Adone*, translated into French *Guzman de Alfarache*, and dedicated odes to Richelieu, Mazarin, and other prominent men (1646-'57). Richelieu gave him a pension of 5,000 francs for his lessons in poetry, and consulted him in regard to the foundation of the academy, of which Chape-

lain was one of the first members. He regulated its functions, drew up the plan of a dictionary and a grammar, and was the literary reviewer of *Le Cid* on behalf of the new institution. In 1672 Colbert employed him in defining the position of contemporary writers for the guidance of the king in awarding pensions. His prose was better than his verse, and his *La Pucelle*, on which he had been engaged for 20 years, made him the butt of Boileau, and later of Voltaire, whose kindred work was published by him as a parody of Chapelain's. Nevertheless, after the publication of the first 12 cantos in 1656, six editions were rapidly sold within 18 months. The remaining 12 cantos were never published; the MS. of the whole work, revised by the author, is preserved in the national library, and several other MS. copies of the last 12 cantos are extant. He was a friend of Boileau, La Fontaine, Racine, and Molière. The last named, whom he had aided in his earlier comedies, dispensed with his literary assistance after Chapelain's luckless attempt in preparing for him a scene of *Les facheux*. He was however extremely popular, and his eulogy was pronounced by D'Alembert. He was a *gourmet*, and was said to have chiefly admired his mistress Mme. Chouars because of her excellent wines. His and Bachaumont's experience as fellow travellers are recorded in the *Voyage de Chapelle et Bachaumont*, one of his most popular works. Tenant de Latour published in 1854 his posthumous poems, together with *Le voyage d'Encausse*. A comic opera based upon the adventures of Chapelle and Bachaumont, was produced under that title in Paris in 1858.

CHAPEL HILL, a post village of Orange co., North Carolina, 28 m. N. W. of Raleigh; pop. in 1870, 2,799. It occupies a healthy and agreeable site on the New Hope river, an affluent of the Cape Fear, and is the seat of the university of North Carolina, an institution founded in 1789. (See NORTH CAROLINA, vol. xii., p. 494.)

CHAPIN, Edwin Hubbell, D. D., an American clergyman, born at Union Village, Washington co., N. Y., Dec. 29, 1814. Having finished his preparatory studies at a seminary in Bennington, Vt., he commenced preaching in Richmond, Va., where he became pastor of a congregation composed of Unitarians and Universalists. In 1840 he removed to Charlestown, Mass., in 1846 to Boston, and in 1848 to New York, where he was installed as pastor of the fourth Universalist church. Of this organization he still remains pastor, although the location of its place of worship has been twice changed during his pastorate. It first occupied a church in Murray street, which had been used for many years by a Dutch Reformed congregation; in 1842 the society removed to an edifice on Broadway, built for and long occupied by the Unitarian church of All Souls; and in 1866 completed the erection of its present house of worship in Fifth avenue at the

corner of Forty-fifth street. In 1856 Mr. Chapin received the degree of D. D. from Harvard college. Dr. Chapin usually preaches twice every Sunday. One discourse is written out, and the other is generally extempore, as far as form is concerned. He is also a favorite lecturer and brilliant popular orator. Besides several volumes of sermons, he has published "Duties of Young Men," "Duties of Young Women," "Characters in the Gospel," "Communion Hours," "Discourses on the Lord's Prayer," "Crown of Thorns," "The Beatitudes," "Moral Aspects of City Life," "Humanity in the City," "True Manliness," and "Discourses on the Book of Proverbs."

CHAPIN, Stephen, D. D., an American clergyman, born in Milford, Mass., Nov. 4, 1778, died in Washington, D. C., Oct. 1, 1845. He graduated at Harvard college in 1804, studied theology with Dr. Emmons, and in 1805 became pastor of the Congregational church in Hillsborough, N. H. Disagreeing with his church in reference to what was known as the "Half-way Covenant," his pastoral relation in Hillsborough was severed early in 1809, and he became pastor of the Congregational church in Mount Vernon, N. H. The controversy into which he had been drawn in Hillsborough led him to a more particular examination of the whole subject of church membership and church ordinances, the result of which was his adoption of the general views held by the Baptist denomination. He accordingly relinquished his charge in Mount Vernon in 1818, and in 1819 became pastor of the Baptist church in North Yarmouth, Me., where he remained till 1822, when he was appointed professor of theology in the college at Waterville, Me. In 1828 he became president of Columbian college at Washington, D. C., and continued to preside over it till 1841, when he resigned.

CHAPIN, William, an American instructor of the blind, born in Philadelphia in 1802. Much of his earlier life was occupied in literary pursuits. He was the author and publisher of a gazetteer and map of the United States, and of other works; and was for six years commissioner of schools in Yates co., N. Y., where he did much to advance the cause of education. In 1840 he was appointed superintendent of the Ohio state institution for the blind, and was successful in improving the system of education there, and in awakening public interest in the institution. Having investigated kindred institutions in various parts of the United States, he visited Europe in 1845, examined nearly all the public charities in England and Paris, and embodied the results of his investigations in a report to the Ohio legislature, "On the Benevolent Institutions of Great Britain and Paris." Resigning his post in Ohio in 1846, he removed to New York, and established a female institute and normal school, which he carried on till 1849, when he was appointed principal of the Pennsylvania institution for the instruction of the blind, in Philadelphia. He prepared the article

on the blind in the United States census report of 1860.

CHAPLET. See BEAD.

CHAPLIN, Jeremiah, D. D., an American clergyman, born at Rowley, Mass., Jan. 2, 1776, died at Hamilton, N. Y., May 7, 1841. He graduated at the college of Rhode Island, afterward Brown university, in 1799, and was tutor there for about three years. In 1802 he became pastor of the Baptist church in Danvers, Mass., where he remained till 1818, when he was selected to take charge of the literary and theological seminary in Waterville, Me. This institution was changed into a college in 1820, and Dr. Chaplin was elected its first president. He administered the government of the new college with success for about 12 years, when he became pastor of the Baptist church in his native town. Subsequently he was pastor of the Baptist church in Willington, Conn.

CHAPMAN, George, an English poet, born at Hitching Hill, Hertfordshire, in 1557, died in London, May 12, 1634. After studying two years in Trinity college, Oxford, where he was distinguished for his knowledge of the classics, he went in 1576 to London, where he enjoyed the friendship of Spenser, Shakespeare, Marlowe, and Jonson, and the patronage of King James and Prince Henry. He published a translation of 7 books of the Iliad in 1598; of 12 books in 1600; and of the whole poem in 1603. It is in the lofty 14-syllable English verse, and of a vigorous and imaginative character, more according with the spirit than the letter of the original. It has retained its popularity both with poets and scholars, though less polished and less accurate than later versions. Pope said that it was "something like what one might imagine Homer himself would have written before he arrived at years of discretion;" Waller could not read it without transport; and Keats has expressed his admiration of it in one of the most beautiful of his sonnets. Chapman afterward translated the Odyssey, the Homeric hymns, and portions of Ovid, Terence, Musæus, and Petrarch. He was also a voluminous writer of plays, only passages of which are now esteemed. He was associated with Jonson, Marston, and others in writing the comedy of "Eastward Ho!" which contained severe satirical reflections upon Scotchmen, and was therefore so distasteful to King James that he caused the authors to be for a short time imprisoned. An imitation of Terence, entitled "All Fools," was highly applauded by his contemporaries; and portions of his tragedy of "Bussy d'Ambois" were highly esteemed by Charles Lamb. A handsome edition of his translation of Homer was published in London in 4 vols. in 1858, and an edition of his complete dramatic works was announced in 1873.

CHAPMAN, John Gadsby, an American artist, born in Alexandria, Va., in the early part of this century. Early indicating his taste for design, he was enabled by the liberality of a

friend to visit Rome, and to study and practise his art there for several years. After his return to the United States he had a studio for some time in New York, but since 1848 he has resided in Rome. He has executed many original designs for the illustration of books. His principal paintings are the "Baptism of Pocahontas" for one of the panels in the rotunda at Washington, the "Israelites Spoiling the Egyptians," "Etruscan Girl," "A Donkey's Head," "The Last Arrow," and "First Italian Milestone." He has also published two books on drawing.

CHAPONE, Mrs. (HESTER MULSO), an English authoress, born in Northamptonshire in 1727, died at Hadley in December, 1801. She is said to have written a romance at the age of nine years, and she early studied several languages and treatises on morals and philosophy. Her first publications were the story of "Fidelia" in the "Adventurer," and some verses prefixed to Miss Carter's translation of Epictetus. In 1760 she married Mr. Chapone, who died within less than a year. In 1770 she accompanied Mrs. Montague to Scotland, and at her request soon after published her "Letters on the Improvement of the Mind." In a volume of "Miscellanies," which subsequently appeared, are several letters addressed by her to Richardson, controverting some of the maxims put forward by him in "Clarissa Harlowe."

CHAPOO, a seaport of China, in the province of Che-kiang, 53 m. N. N. W. of Ningpo, in lat. 30° 40' N., lon. 120° 25' E. It is situated on the N. side of the estuary of the T sien-tang, its suburbs lying along the shore, while the main town is at some distance behind them. Through the suburbs is conducted its extensive trade with foreign ports; while a canal connects the city itself with Hang-chow, and thus with the interior. Chapoo is an important entrepot in the trade between China and Japan; and although its harbor is shallow and unsafe, it has attained great importance as a port. It was the scene of a severe conflict in the opium war, when the heights near by, which had been fortified by the Chinese, were carried by the British after an obstinate resistance, May 18, 1842.

CHAPPE, Claude, a French engineer and mechanic, born at Brulon in 1763, died Jan. 23, 1805. Having invented an ingenious system of signals to communicate at a distance with his friends, he presented it to the French legislative assembly in 1792. It was successfully tried between Paris and Lille, on a length of 48 leagues, and was adopted by the government. Chappe established several lines in France, and the one running north was first put in motion to announce the recapture of the town of Condé from the Prussians. The inventor was at once rewarded by the convention, which by a decree appointed him *ingénieur télégraphe*. The lines were extended all over France, and the system was also adopted, with some alterations, through Germany and

England. The attacks to which he was subjected by persons jealous of his invention preyed so much upon his mind that he committed suicide.

CHAPPE D'AUTEROCHE, Jean, a French astronomer, born at Mauriac, Auvergne, in 1722, died in California, Aug. 1, 1769. He was a priest, but giving his whole attention to astronomy, he became one of the assistants of Cassini in delineating the general map of France, and edited the astronomical tables of Dr. Halley. In 1760 he was designated by the academy to make an observation of the transit of Venus over the sun's disk, which Halley announced would happen June 6, 1761. He consequently set out for Tobolsk in Siberia, which was pointed out as the most favorable point of observation. His mission was successfully accomplished; and returning to France at the end of two years, he published in 1768 his *Voyage en Sibérie*. The following year he sailed for California to observe another transit of Venus, which was to take place June 3. He was equally successful on this occasion, but died soon afterward. The results of his last expedition were published by C. F. Cassini, under the title of *Voyage de la Californie*.

CHAPSAL, Charles Pierre, a French grammarian, born in Paris in 1787, died near Joinville-le-Pont, department of the Seine, in 1858. His principal work, jointly with François Joseph Noël, *Nouvelle grammaire française, avec exercices*, passed from 1823 to 1858 through over 40 editions, having been adopted as a standard school book, and still used to some extent, though eclipsed by more recent grammars. He became wealthy by his writings, purchased the château de Polangis, devoted himself to charity, and bequeathed 80,000 francs to the teachers in the outskirts of Paris.

CHAPTAL, Jean Antoine, count de Chanteloup, a French chemist and statesman, born at Nogaret, Lozère, June 5, 1756, died in Paris, July 30, 1832. During his medical studies and practice he devoted much research to the science of chemistry, in which he soon became eminent, and was appointed professor at Montpellier, where he taught successfully the doctrines of Black, Lavoisier, and Cavendish. His uncle, a wealthy physician, left him a fortune, with which he established chemical works near Montpellier, being the first attempted of the kind, and by which he was soon enabled to produce various chemicals hitherto imported such as the mineral acids, alum, soda, and salts of lead. The authorities of Languedoc heaped honors on him; the Spanish government offered him a pension of 56,000 francs to go to Spain; and according to his biographer, Washington wrote three times to Chaptal inviting him to America. After the outbreak of the French revolution he published a political pamphlet, entitled *Dialogue entre un Montagnard et un Girondin*, and was arrested, but through the intercession of friends was liberated. The committee of public safety placed

him in charge of the saltpetre works of Grenelle. Returning to Montpellier, he was elected member of the institute, and devoted himself to science till Bonaparte summoned him to the council of state, where he had the supervision of national education. When Lucien Bonaparte resigned the portfolio of the interior, Chaptal took his place as minister, and retained it for four years. He founded the conservatory, school of arts, and society for encouragement of industry, introduced the modern French system of weights and measures, established a model farm and a system of distribution of agricultural seeds, reorganized the prisons and hospitals, extended the network of highways over the country, and originated the plans of extension of the Louvre and rues de Rivoli and Castiglione, afterward completed by Napoleon III. In the midst of his usefulness a misunderstanding arose between him and Napoleon; some accounts say, because Chaptal refused to report in favor of beet-root over cane sugar, while others assert that it was on account of the actress Mlle. Bourgoïn, to whom both emperor and minister paid their addresses. A reconciliation afterward took place, and the ex-minister was made count, senator, and grand officer of the legion of honor. On Napoleon's return from Elba, the count was appointed director general of commerce and manufactures. Louis XVIII. struck him from the list of peers, but left him on the roll of the academy.

He was however restored to the chamber of peers in 1819. His works are all on chemical subjects, and may yet be consulted with advantage, especially his *Chimie appliquée aux arts* (4 vols. 8vo, Paris, 1806), and *Chimie appliquée à l'agriculture* (2 vols. 8vo, 1823).

CHAPTER, the community of canons or prebendaries attached to a cathedral or collegiate church, and presided over by a dean. (See **CANON**.) They govern the diocese during the vacancy of the see, in some countries have the right of choosing the bishop, and act as his advisers. In England the appointing privilege was assumed by Henry VIII. as a royal prerogative. Some of the Roman Catholic cathedrals in England have their chapters, but there are none in the United States. They were suppressed in France by the civil constitution of the clergy, but restored by the concordat of 1801. The title of chapter is applied not only to the canons in their collective capacity, but also to

their meetings, and to the place in which the latter are held. It is given to the assembly of members of a religious order, to the convocations of the military orders of the middle ages, and even to the meetings of certain corporations of mechanics and tradesmen. It was first used about the 8th century, and is supposed to have originated in the fact that at such sessions it was customary to read some or all of the chapters containing the rules of the community.

CHAPULTEPEC, a Mexican fortress, built upon a rock of the same name, 150 or 200 ft. high, about 2 m. S. W. of the city of Mexico. At the time of the war with the United States it was heavily armed, had a frontage of 900 ft., and defended a causeway which formed the approach to the city. At the base of the hill, in front, was the wall of an aqueduct; in the rear an old powder mill, known as Molino del

Chapultepec.

Rey. The castle was the seat of the national military academy, and was defended by Gen. Bravo and a picked force. Santa Anna, with the greater portion of his army, occupied the city of Mexico, and was in communication with Chapultepec. On Sept. 12, 1847, Gen. Scott first stormed Molino del Rey, then, under cover of a demonstration against the city, brought four batteries to bear upon the castle from an opposite ridge, and after a heavy fire of a day and a half made the attack in two columns, simultaneously upon the E. and W. sides of the fortress. The American loss was slight, the Mexican much heavier. The day after the fall of the castle the city of Mexico was occupied by the American forces.

CHARA, a genus of aquatic plants of the order *characeæ*, found in most parts of the world. In the United States they occur in the great lakes and in the large fresh-water lakes of New York, frequently growing with such luxuriance as to render the bottom green like a grassy

meadow. They are found in the fossil state, and are important to the geologist as characterizing groups of strata, as those of the fresh-water marl beds of the tertiary formation. The seed vessel of these plants is very tough, and is covered by an integument consisting of five spiral valves. The stems are longitudinally striated, and always turn in a contrary direction from the rings on the seed vessel.

CHARBAR (or **Choubar**) **BAY**, one of the best harbors on the coast of Beloochistan, in the Indian ocean. Ras Charbar, the E. point of the bay, is in lat. 25° 16' N., lon. 60° 35' E. On the E. side of its entrance is the town of Charbar, pop. 1,500, surrounded by a rampart of earth, and garrisoned by the sultan of Oman. North of this are the ruins of the Portuguese settlement of Teez, which was probably identical with the Tiz of Edrisi, and possibly occupied the site of the Træsa of Nearchus.

CHARCOAL, the solid residuum of the destructive distillation of wood. Exclusive of hygroscopic water and ash, it is composed of carbon, hydrogen, oxygen, and nitrogen, in proportions varying with the kind of wood, with its hygroscopic condition, with the temperature of the distillation, and with the duration of the process. It is insipid and inodorous; is a bad conductor of heat and a good conductor of electricity; is insoluble in water; is attacked by nitric acid with difficulty, and is but little affected by the other acids or by the alkalis. Its carbon constituent is exceedingly refractory to heat, and if secluded in a retort will neither fuse nor volatilize under the highest temperature that can be produced. It retains the organic structure of the wood from which it was produced, except when prepared at very high temperature, when it becomes a black, shining, porous mass, resembling fossil coal, with a considerable increase in density, and without a trace of organic structure. Charcoal always contains a certain percentage of ash derived from the wood of which it is made, but that percentage is much less than what is due to the respective weights of the original wood and the resulting charcoal, showing that a portion of the mineral matter in the wood has been carried off by the fluid distillates. Charcoal is excessively hygroscopic. A fresh preparation of it strongly attracts moisture from the moment it is exposed to the atmosphere, and the quantity thus absorbed at saturation varies with the temperature of distillation, and with the hygrometric and barometric conditions of the atmosphere. The lower the temperature at which the charcoal is produced, the greater the humidity of the air, and the higher the barometer, the greater is the percentage of moisture absorbed at saturation by the charcoal. Charcoal is hard and brittle; it rings when struck, and resists a strong pressure gradually applied, but is easily broken by a sudden blow, when it shingles like porcelain and shows a glossy, intensely black and glistening fracture, that scarcely black the hand until after some expo-

sure to the air. The quantity of charcoal obtained from the same weight of wood in the same condition, and the ratio of its carbon constituent to its hydrogen, oxygen, and nitrogen, vary with the temperature and time of distillation; the lower the temperature and the shorter the time, the greater is the percentage of charcoal obtained, and this charcoal contains a greater percentage of hydrogen, oxygen, and nitrogen, and less of carbon; but the highest temperature and the longest application fail to wholly expel the volatile constituents of charcoal. The ordinary charcoal of commerce, prepared in heaps at the temperature of about 700° F., has the density of 0.42 including its pores, and of 1.50 excluding them. In the merchantable state it weighs 15½ lbs. per cubic foot, and requires 144½ cubic feet of space to contain one ton. The following is its chemical constitution by weight, both including and excluding its ash and hygroscopic moisture:

	Inclusive of ash and Hygroscopic moisture.	Exclusive of ash and Hygroscopic moisture.
Carbon	70	80.46
Hydrogen	5	5.75
Oxygen	11	12.64
Nitrogen	1	1.15
Ash	2
Hygroscopic } moisture }	11
	100	100.00

When the distillation is done under a temperature of about 1,500° F., charcoal has the density, exclusive of pores, of about 1.75, and the following chemical constitution by weight, both including and excluding its ash and hygroscopic moisture:

	Inclusive of ash and Hygroscopic moisture.	Exclusive of ash and Hygroscopic moisture.
Carbon	88.0	91.21
Hydrogen	2.5	2.75
Oxygen	5.0	5.49
Nitrogen	0.5	0.55
Ash	3.0
Hygroscopic } moisture }	6.0
	100.0	100.00

The ash of charcoal consists chiefly of carbonate of potash, silica, lime, and oxide of iron. When wood is distilled to the uttermost, at the temperature of 2500° F., the resulting dry charcoal, exclusive of its pores, has a density of about 2, and contains about 3 per cent. of volatile matter. The specific heat of good charcoal, free from hygroscopic moisture, increases with the temperature, and in the following ratio: At 212° F. the specific heat is 0.2415; at 392°, 0.2441; at 572°, 0.2467; at 752°, 0.2493; at 932°, 0.2519; at 1112°, 0.2545; at 1292°, 0.2571; at 1472°, 0.2597; at 1652°, 0.2623; at 1832°, 0.2649; at 2012°, 0.2675; at 2192°, 0.2701; at 2372°, 0.2727; and at 2552°, 0.2753.—Charcoal absorbs the fixed gases as well as aqueous vapor with great avidity, the volumes at standard temperature and pressure absorbed by the same charcoal varying with the temperature and pres-

sure of the gas; the lower the former and the greater the latter, the greater the absorption. In function of pressure alone, the temperature being constant, the same charcoal absorbs volumes of gas nearly, but a little less than, in the direct ratio of the pressure. The amount of absorption differs greatly for the charcoal of different woods, other things being equal; and for the temperature at which it was formed from the same wood, the lower that temperature the greater the absorption. If charcoal saturated with one gas be exposed to another gas, it will discharge a portion of the former and absorb a portion of the latter, so that it will contain both gases, but not in so great quantities of each as if it were exposed to each alone. Recently prepared charcoal exposed to the atmosphere absorbs the oxygen of the air to a greater extent than the nitrogen. Damp charcoal does not absorb gases so readily nor to the same quantity as that which is dry. Charcoal loses its property of absorption by use, but regains it completely by simple reheating. The absorption of gases is always accompanied by a rise of temperature in the mass. If dry charcoal saturated with sulphuretted hydrogen be introduced into oxygen, the gases combine with explosion and the production of aqueous vapor and sulphurous acid gas; just previous to the explosion a yellow vapor, that of the separated sulphur, exudes from the pores of the charcoal. If nitrogen be mixed with the oxygen, the above effect is produced more slowly, and the hydrogen alone of the sulphuretted hydrogen is combined, its sulphur being precipitated as a solid. The absorption by charcoal of gases and vapors attains its maximum in about 36 hours; and damp charcoal does not absorb them so readily as that which is dry. This absorbent property of charcoal is ascribed to catalysis, and resembles the action of spongy platinum on certain mixtures of gases; but there is this difference between the two substances, that platinum has the greater combining power, while charcoal has the greater absorbing power. Coarsely powdered charcoal boiled in a solution of the chloride of platinum until thoroughly soaked, and then heated to redness in a closed crucible, retains a portion of the platinum, and possesses remarkable powers of absorption and combination. Charcoal has a great deoxidizing power even at low temperatures; it is, in fact, the great reducing agent of metallurgists. Fresh-burned charcoal of boxwood, free of ashes, introduced into nearly neutral and very dilute solutions of gold, platinum, palladium, silver, and copper, precipitates the metals, which are deposited on the charcoal in thin films. The deposit of copper, if allowed to remain in the liquid, soon disappears. Zinc, iron, lead, and mercury are precipitated in the same manner, but redissolve in acid liquors. At a red heat charcoal deoxidizes many fixed and volatile metallic oxides (arsenious acid), reproducing their metal-

lic bases. At a white heat it deoxidizes even potassa, soda, and phosphoric acid, setting free in vapor potassium, sodium, and phosphorus. Charcoal produces in the cold a violent explosion with perchloric acid; and at a red heat it deoxidizes the chlorates, perchlorates, and nitrates, with deflagration, producing carbonates with the respective alkaline bases. At a full red heat it converts most of the sulphates to sulphites, and it decomposes water; but it has no action on the haloid salts, namely, the chlorides, bromides, iodides, and fluorides; neither does it decompose, even at a very high temperature, silica and alumina. When the vapor of water is passed slowly over charcoal heated to full redness in a porcelain tube, the resulting gas, called water gas, is composed by weight, in 100 parts, of hydrogen 56.03, carbonic oxide 29.15, carbonic acid 14.65, and carburetted hydrogen 0.17. The absorbing and deoxidizing powers of charcoal are greatly diminished by saturation with water. Charcoal has also a strong deodorizing power, referable to the same property. If air containing sulphuretted hydrogen be agitated with powdered charcoal, or if water containing sulphuretted hydrogen be filtered through charcoal, the offensive odor of that gas is speedily removed. The sulphuretted hydrogen is first absorbed, and then, by a catalytic action, its hydrogen unites with the oxygen of the atmosphere, while its sulphur is deposited. Charcoal absorbs coloring matters. Powdered charcoal agitated with solutions of dilute sulphate of indigo, of cochineal, of the blue iodide of starch, and of the red permanganate of potassa, entirely removes these colors. Port wine, by a similar process, is rendered tawny or light-colored; and impure solutions of sugar and nitre lose their color by filtration through a mass of charcoal. The taste of liquids in some cases is almost removed by filtration through charcoal when the taste depends on the presence of certain organic substances. The bitterness of the hop in ale is thus removed, and strychnia, too, is completely absorbed. The antiseptic power of charcoal is due to the action of its absorbed oxygen upon organic matter, under the influence of which the decomposition of such matter is quickened instead of retarded. Charcoal, by its possession of these properties of absorption, decomposition, and combination, is eminently fitted as a filter for the purification of water, removing from that liquid the color, odor, and taste of its impurities, by oxidizing and recombining them into other and inoffensive substances. The following gases stand in their respective order as regards their volumes at standard temperature and pressure, which are absorbed at saturation by dry charcoal; the first named being absorbed in least volumes, and the volumes increasing for each gas to the last named; the absolute number of volumes in each case varies enormously with the charcoal of different woods and with the

temperature at which it was made: 1, hydrogen; 2, nitrogen; 3, carbonic oxide; 4, oxygen; 5, marsh gas; 6, nitrous oxide; 7, carbonic acid; 8, olefiant gas; 9, sulphurous acid; 10, air; 11, sulphuretted hydrogen; 12, muriatic acid; 13, hydrochloric acid; 14, ammonia. —When air-seasoned wood, that is to say, wood containing about 25 per cent. by weight of hygroscopic water, is slowly charred in heaps at a temperature of about 750° F., about one third of it is wholly consumed in producing the heat required for the charring, leaving two thirds for the portion charred. The dry charcoal produced is 16 per cent. of the total weight of wood; that is, of the sum of the weight consumed and the weight charred, or $\left(\frac{16 \times 100}{66\frac{2}{3}}\right)$ 24 per cent. of the latter. When the wood is slowly distilled in ovens or retorts at the above temperature, then, as the same quantity of heat is required for producing the same effect, for every two pounds put into the retort one pound will be consumed beneath it to produce the heat for distillation. Of the two pounds thus distilled, 24 per cent. is obtained as dry charcoal; or, of the total weight of wood used, that is, of the sum of the weights consumed and the weight distilled ($\frac{2}{3}$ of 24), 16 per cent. is obtained as dry charcoal. Consequently, for equal weights used of the same wood, the process of distillation in retorts and that of charring in heaps are equally economical; in the former case, however, the gaseous and liquid distillates belonging to two thirds of the wood are saved, while in the latter case they are lost. When the charring or distilling is very rapidly done, the resulting weight of dry charcoal is only 14 per cent. of that of the wood charred or distilled; and the quantity of wood consumed in the production of the heat required for the charring or distilling is equal to the weight of wood charred or distilled; consequently, in this case, only 7 per cent. of the total weight of wood used is obtained as dry charcoal. The proportion of charcoal obtained from wood varies with the kind of wood, and for the same kind of wood it varies with the temperature and with the duration of the charring or distillation; the lower the temperature and the longer the duration of the process, the greater is the proportion of charcoal obtained. The charcoal also varies in chemical composition with the temperature and the duration of the charring or distilling process. The lower the temperature, other things being equal, the greater is the percentage of volatile matter and the smaller that of fixed carbon in the charcoal. The hygroscopic power of such charcoal is greater than of that prepared at higher temperatures. The longer the process of preparation is continued, other things equal, the less is the percentage of volatile matter and the more that of fixed carbon in the charcoal. The hygroscopic power of such charcoal is less than of that prepared with shorter processes. No

temperature at the command of man, and no time of distillation, will wholly expel the volatile constituents of charcoal, namely, the hydrogen, oxygen, and nitrogen.—The inflammability of dry charcoal varies with the kind of wood from which it is made; and for the same kind of wood it varies with the temperature and with the duration of the charring or distillation; the lower the temperature and the shorter the duration of the process, the more inflammable is the charcoal. The relative inflammability is measured by the temperature of ignition; the lower that temperature, the more inflammable is the charcoal. The inflammability depends on the porosity of the charcoal and on the percentage of its volatile constituents, and both these are greater the lower the temperature of the charring or the distillation and the shorter the time. After a brief exposure of dry charcoal to the atmosphere, its large absorption of hygroscopic moisture materially modifies the above relations, and tends to equalize its inflammability, as the lower the temperature and the shorter the process of the charring or distillation, the more hygroscopic is the charcoal, and consequently the higher is its temperature of ignition. The temperatures of ignition of dry charcoal prepared at various temperatures are as follows:

Temperature of the Charring.	Temperature of Ignition.
500° F.	650° F.
600	700
1000	750
2000	1100
3000	1450

It is obvious that the dryer the wood, the greater is the percentage of charcoal obtained from it, and the less is that of the wood required to be consumed in producing the heat for the charring or distillation; for the uncombined water in the part of the wood charred or distilled is entirely driven off as aqueous vapor during those processes; while in the part of the wood consumed to produce the heat for the charring or distillation, the uncombined water is not only driven off, but also absorbs for its evaporation a portion of the heat due to the combustion of the ligneous matter. A further portion of that heat is taken, too, for the evaporation of the water in the part of the wood charred or distilled, so that the greater the quantity of uncombined water in a given weight of wood, the greater is the percentage of the part required to be consumed in producing the heat for the charring or distilling. Thus, of the total weight of wood used, that is, the sum of the weight charred or distilled and consumed in producing the heat for the charring or distillation, the effect of the uncombined water is to diminish the charcoal product more largely than is due to the simple subtraction of that water by the amount of wood consumed for its evaporation. This is the only result attending the presence of water in the wood when the temperature of the charring or dis-

tillation is kept below that of a red heat. If that temperature be exceeded, however, the aqueous vapor, in passing over the red-hot charcoal, reacts upon its carbon constituent and converts a portion of it into carbonic acid, carbonic oxide, and carburetted hydrogen; all of which pass off in the gaseous form, diminishing the charcoal products by the amount of carbon they contain. If, of two equal weights of the same wood containing equal weights of uncombined water, one weight be dried while the water is allowed to remain in the other, the two masses will contain equal weights of ligneous matter; and if they be charred or distilled at less than a red-heat temperature, under the same conditions, the same weight of charcoal will be obtained from the charred or distilled part of each. One pound of charcoal, having the chemical constitution given for it in the early part of this article, develops sufficient heat by combustion in oxygen to raise the temperature of 12,306·414 lbs. of water, at the temperature of 32° F., one degree, or to evaporate under the atmospheric pressure 12·743 lbs. of water from the temperature of 212° F. One pound of what remains of this charcoal, after deducting its ash and hygroscopic water, will develop sufficient heat by combustion in oxygen to raise the temperature of 14,288·837 lbs. of water, at the temperature of 32° F., one degree, or to evaporate under the atmospheric pressure 14·796 lbs. of water from the temperature of 212° F. Equal weights of charcoal from all varieties of wood, prepared under equal conditions, have the same heating power.—In the ordinary mode of manufacturing charcoal in heaps, the sticks of wood are piled up, sometimes in horizontal and sometimes in vertical layers, around a central opening which extends from the bottom to the top of the heap. The heaps are conical or hemispherical, from 10 to 30 or 40 ft. in diameter, and of a height of about 12 ft.; their outer surface, after being made even with chips and twigs, is covered with small branches, leaves, straw, or moss, upon which sods are laid together with the charcoal dust of previous burnings. This dust is mixed with sufficient earth to give it consistency, and when moistened the mixture makes the best of all coverings. The sticks of wood to be charred are of any convenient size, and are closely packed, the interstices of the larger sticks being filled with smaller ones. The central vertical opening in the heap is left for a chimney, and for the introduction of the fire to ignite the heap; to facilitate the latter, a horizontal opening is left in the bottom of the heap, extending from its periphery to the central opening. Around the bottom of the heap other smaller openings are made for the admission of air and the escape of the volatile products. As the charring process proceeds, these small openings are closed, and new ones made nearer the top of the heap, and in other places, as it is found desirable to check the process in some parts and to hasten it

in others. The heap is fired in the centre at the bottom, and the fire gradually spreads in all directions, but especially toward the openings by which the air is admitted. The first matter that escapes is aqueous vapor, which partly condenses in the cover of the heap, moistening it, and then passes off with a yellowish color. After the vapor disappears, it is followed by a lighter-colored smoke that becomes black and dense, emitting the odor of pyroligneous acid, which grows stronger to the end of the process. The carbonization, first completed at the centre and top of the heap, gradually extends down its sides; and in a heap half charred, the finished portion has the form of an inverted cone, the apex of which is at the bottom of the vertical axis of the heap. As the line between the finished and unfinished portions moves downward, the openings for the admission of air are kept in advance of it, and upper openings are closed as lower ones are made. The completion of the charring of each part of the heap is indicated by the smoke emerging from that part changing from its black and dense appearance to a transparent light bluish color. The tarry matters, which collect mostly toward the close of the operation, run out in channels made for that purpose beneath and around the heap. When the entire heap is completely charred, all its openings are closed, and it is then left for one or two days, after which it is partially uncovered and the charcoal drawn out and spread around in thin layers. This is best done at night, so that if any of the charcoal remains ignited, it can be quickly seen and quenched. The time required for the process varies with the size of the heap and the state of the weather. Small heaps may be charred in a week, and large ones may require three weeks. A common yield from one cord (128 cubic feet) of wood is about 30 bushels of charcoal.—Animal charcoal has been described under **BONE BLACK**.

CHARDIN, Jean, a French merchant, born in Paris in November, 1643, died in London in January, 1713. He went to the East to trade in jewelry, became the favorite purveyor of the shah of Persia, and eventually produced a book of his travels and experiences in that country, which has been found true by subsequent travellers, and translated into many foreign languages. The London edition of 1686 contains only the description of his journey to Ispahan. Complete editions of the work, which is entitled *Journal du voyage du chevalier Chardin en Perse et aux Indes Orientales, par la Mer Noire et par la Colchide*, appeared in 1711 and 1735. The most highly valued edition is that of Langles, the orientalist, who enriched it with a map, and with an abridged history of Persia (Paris, 1811). A Protestant by birth, Chardin was compelled on his return from the East in 1681 to seek refuge in England, where he was knighted and appointed agent of the East India company in Holland.

CHARDIN, Jean Baptiste Siméon, a French painter, born in Paris about 1699, died Dec. 6, 1779. The son of a workman, and without teachers, he yet reached eminence, and became a member of the academy in 1728. He excelled in painting still life, flowers and fruits, and subsequently in delineating the life of the middle classes. His *Bénédictine* in the Louvre, representing a woman reciting prayers before dinner to her two children, gave him a wide reputation, and was regarded by Diderot as superior even to Greuze. He was in his 80th year when he exhibited his "Jacquet;" and shortly after he painted an admirable portrait of himself, which is in the Louvre.

CHARENTE, a W. department of France, bordering on the departments of Vienne, Haute-Vienne, Dordogne, Charente-Inférieure, and Deux-Sèvres; area, 2,294 sq. m.; pop. in 1872, 367,520. It is formed principally out of the ancient province of Angoumois, and derives its name from the river Charente, by which it is drained. The soil is generally far from being fertile. There are many shallow ponds, called *étangs*, some of them of considerable extent. Numerous caverns, some of great depth, are found, among which that of Rancogne, near La Rochefoucauld, is particularly remarkable. It seems as if earthquakes had been once frequent here. Two rivers, the Tardouère and the Bandiat, the course of which is toward the Charente, disappear repeatedly, and finally are entirely lost before reaching that river. There are mines of iron, antimony, and lead, and quarries of free and rag stone. The grain crop is poor, and scarcely sufficient for home consumption; but the vineyards, covering about 24,000 acres, yield a considerable surplus. Their produce is mostly converted into brandy, the superiority of that made at Cognac being universally acknowledged. Hemp, flax, and potatoes are extensively cultivated. Truffles are abundant, as well as chestnuts. Cattle, mules, and asses are numerous; horses are comparatively scarce. Game, fish, poultry, and bees are found in abundance. Besides large iron works connected with the mines, there are paper mills, especially at Angoulême, distilleries, manufactories of earthenware, &c. The export trade is mostly in brandy, which is forwarded to nearly all parts of the world. Nearly 900 fairs are annually held in the department. It is divided into the arrondissements of Angoulême, Ruffec, Cognac, Confolens, and Barbezieux. Capital, Angoulême.

CHARENTE-INFÉRIEURE, a W. department of France, on the Atlantic coast, bordering on Vendée, Deux-Sèvres, Charente, Dordogne, and Gironde; area, 2,635 sq. m.; pop. in 1872, 465,653. Besides being intersected by the Charente, it is watered on the N. frontier by the Sèvre-Niortaise, and on the S. by the Gironde, which offer great facilities to exterior commerce. There are several other navigable streams, and a canal connecting La Rochelle with Niort. The climate is agreeable; the surface is flat,

and partly covered, especially in the neighborhood of the sea, with marshes yielding large quantities of salt. There are quarries of freestone; peat, and fine sand for the manufacture of glass, are also found. The soil is mostly calcareous or sandy, but yields large crops of grain and wine. Large quantities of brandy are exported. Cattle, horses, and sheep are raised in great numbers. Oysters are sent to Paris and London. Sardines form an important branch of trade, and vessels are fitted out for the cod fishery. La Rochelle, Rochefort, and the other ports have a considerable share of the colonial and coasting trade of France. There are manufactories of coarse woollen stuffs, soap, fine earthenware, and glass, with tanneries and sugar refineries. The islands of Oléron, Ré, and Aix lie near the coast of this department. It is divided into the arrondissements of La Rochelle, Rochefort, Marennes, Saintes, Jonzac, and St. Jean d'Angély. Capital, La Rochelle.

CHARENTON-LE-PONT, a town of France, in the department of Seine, on the right bank of the Marne, near its confluence with the Seine, 5 m. S. E. of the centre of Paris; pop. in 1866, 6,190. It derives its surname from the fine bridge which, crossing the Marne, unites the town with the village of Alfort. This bridge has been always considered as of great importance for the defence of Paris, and is protected by the fort of Charenton, near Alfort, which guards the passages of both rivers.

CHARENTON-ST.-MAURICE (the name changed to St. Maurice since 1842), a village of France, in the vicinity of Paris, on the right bank of the Marne, about 1 m. E. of Charenton-le-Pont; pop. in 1866, 4,931. It contains an excellent lunatic asylum, founded in 1741, and capable of accommodating 500 patients. The Protestants formerly had here a large church, in which several synods were held; but it was demolished in 1685, on the revocation of the edict of Nantes.

CHARES. I. An Athenian general, first mentioned in 367 B. C., when he was sent to the aid of the Phliasians, whom he relieved from siege by the Arcadians and Argives. He was next sent to take command against Oropus, and in 361 succeeded Leosthenes, who had been defeated by Alexander of Phœæ, and, sailing to Corecyra, aided an oligarchical conspiracy to overthrow the democracy, a proceeding that resulted in the loss of that island to Athens at the outbreak of the social war. Sent to Thrace in 358, he compelled Charidemus to ratify the treaty he had made with Athenodorus. The following year, with Chabrias, he commanded the forces in the social war, and made an unsuccessful attack upon Chios, in which his colleague was slain. In 356 Iphicrates and Timotheus were joined with him in the command; but he soon procured their recall by accusing them to the people, and entered into the service of Artabazus, the revolted satrap of western Asia. This act was at first ap-

proved but afterward condemned by the Athenians. He subsequently led an expedition against Sestos, which town he took, and served with little success in the Olynthian war. In 346 he was in command in Thrace, but seems to have been engaged in private plunder rather than in fighting the enemy. In 340 he was sent to aid the Byzantines against Philip, but his character was so distasteful to them that they refused to receive him. In 338 he was one of the Athenian generals at the disastrous battle of Charonea. He appears to have died at Sigeum a few years afterward. He was not endowed with superior military ability, yet was apparently the best qualified Athenian of his time for command. He seems to have won and maintained his ascendancy over the people partly by his athletic figure, partly by flattery and corruption. **II.** A Grecian statuery in bronze, the designer of the statue known as the colossus of Rhodes, was a native of Lindus, the favorite pupil of Lysippus, and flourished in the beginning of the 3d century B. C.

CHARETTE DE LA CONTRIE, François Athanase, a Vendean soldier, born at Couffé, April 21, 1763, executed in Nantes, March 29, 1796. He was a member of an ancient Breton family, his branch adding the surname La Contrie after their manor. He was educated at the college of the Oratorians in Angers, entered the navy in 1779, and took part in the American war. He was among the *émigrés* after the outbreak of the revolution, but soon returned to Paris, took part in the defence of the Tuileries, and then retired to his estates in Brittany. In March, 1793, the peasantry obliged him to become their commander, and gaining several victories over the republican troops, he was soon regarded as the insurgent leader in lower Vendée, and shared with Stofflet in the supremacy of the whole royalist camp, especially after the execution of their commander Marigny for neglect of duty, by order of a court martial. The count d'Artois promoted him to the rank of lieutenant general in July, 1794, and he soon assumed supreme authority in lower Vendée. A treaty of peace, signed Feb. 19, 1795, proving abortive, Charette resumed a guerilla warfare which was now more hopeless than ever, owing to Hoche's energetic operations as commander-in-chief of the republican army. But though completely exhausted, and finally routed, he nevertheless urged upon the allies the recognition of Louis XVIII. Declining the most honorable terms of capitulation, with only 33 men he attempted on March 23, 1796, to fight his way through the republican ranks, but was wounded, captured, and taken to Nantes, where he was shot by sentence of a court martial. The future Louis XVIII., who called him "the second founder of the monarchy," delivered a speech in his honor at the commemoration of his death, celebrated on May 6, 1796, at the headquarters of Condé's army.

CHARGÉ D'AFFAIRES, the title of the fourth rank of diplomatic agents. They are accredi-

ed not to the sovereign but to the department of foreign affairs, and are appointed by and responsible to the minister of state of their own country. They were not recognized in European diplomacy till near the 18th century. By the congress of Vienna in 1815 they were made the third order of diplomatists, which was changed to the fourth by the congress of Aix-la-Chapelle in 1818. The title is given to the agent whom an ambassador or envoy, by virtue of authority from his prince or state, appoints to conduct in his absence the affairs of his mission.

CHARITÉ, La, a town of France, in the department of Nièvre, situated on the Southern railway and on the right bank of the Loire, over which there are two bridges, 12 m. N. N. W. of Nevers; pop. in 1866, 4,870. It has manufactures of coarse jewelry and earthenware and woollen stuffs.

CHARIOT, among ancient nations, a two-wheeled carriage, open above and behind and closed in front, and used in war, in public games, and for the purposes of common life. The axle of the Greek chariot was usually made of oak, ash, or elm, though Homer describes the chariots of Juno and Neptune as having metallic axles. The wheels were about

Roman Chariot.

four feet in diameter, and each consisted of a nave bound with an iron ring, of spokes, a felly of elastic wood, and a heavy iron tire. They were fastened to the axle by pins, and the overthrow of Enomaus in his contest with Pelops was caused by the treachery of his charioteer, who inserted a linchpin of wax. The Lydians and Romans sometimes attached two or three poles and spans of horses to their chariots, but the Greeks rarely added a third horse. From the earliest historic periods chariots were used in war both by the Asiatic and the classic nations. The famous scythe chariots, whose spokes were armed with long hooks and sickles, were chiefly used by the ancient Persians, Britons, and Gauls. The warriors of highest rank among the Hebrews, Greeks, and Romans either fought from their chariots, or sometimes in close combat dismounted. In the Roman games chariots were often decorated with sculptures and enriched with gold and ivory. The triumphal chariot, which was usually made of ivory, adorned with the utmost skill, and drawn by four white

horses, was one of the chief ornaments in the celebration of a victory. The chariot was an

British Chariot.

attribute of the mythologic divinities, especially of Victory, Night, Apollo, and Diana.

CHARISTICARIES, the name applied in Greek ecclesiastical history to functionaries who possessed uncontrolled power over the revenues of hospitals and monasteries. The practice originated during the iconoclastic struggle in the 8th century, and resulted from hostility to monasticism. In after times the custom was continued without the spirit which originated it, and monasteries were often given to persons of wealth and rank in order to secure their patronage and influence.

CHARITON, or **Grand Chariton**, a river which rises in Lucas co., Iowa, and flows S. E. through Appanoose co. to the Missouri boundary. Thence it follows a S. course to the Missouri river, which it joins near the S. extremity of Chariton co., Missouri. It is about 250 m. long, and is navigable for 50 m. The East Chariton and Middle fork are its principal branches.

CHARITON, a N. central county of Missouri, intersected by Chariton river, and bounded S. W. by the Missouri and W. by Grand river; area, 740 sq. m.; pop. in 1870, 19,136, of whom 2,800 were colored. Yellow and Wolf creeks furnish water power. The soil is fertile and adapted to pasturage. The surface is gently undulating and covered with forests and prairies. Stone coal and limestone are found in large quantities. The North Missouri railroad crosses it. The chief productions in 1870 were 205,851 bushels of wheat, 919,288 of Indian corn, 205,914 of oats, 65,593 of potatoes, 4,137 tons of hay, 219,697 lbs. of butter, 39,833 of wool, and 2,993,981 of tobacco. There were 6,169 horses, 1,973 mules and asses, 5,280 milch cows, 8,085 other cattle, 15,689 sheep, and 27,461 swine. Capital, Keytesville.

CHARITY, **Brothers of**, a religious order in the Roman Catholic church, established at Seville by St. John of God in 1540. He hired a house to harbor poor sick persons, in which he provided for them and served them himself with great devotion. This pious work of charity attracted the attention of the whole city, and gradually persons of the same disposition as John came to aid him in his undertaking. His

institution was approved by the archbishop, but the members of it had neither rule nor habit, and it did not receive the approval of the pope until after the death of its founder. In 1572 Pius V. gave it the rule and habit of St. Augustine. Maria de' Medici introduced the order into France in 1601. Henry IV. granted it letters patent in 1602, and it soon numbered several houses in that kingdom. The hospital La Charité in Paris, and that of Charenton, were the most important. The brothers of charity not only nursed the sick, but were frequently skilful surgeons. In Spain these religious were called brothers of hospitality, and in Italy *frate ben fratelli*. They are now almost extinct. The various orders of brothers hospitallers have been superseded by sisterhoods.—A new religious order of brothers of charity was founded in 1828 by Cardinal Rosmini-Serbatì. They possess several flourishing houses in England.

CHARITY, **Sisters of**, a religious congregation founded by St. Vincent de Paul in the vicinity of Paris about the year 1633, with the coöperation of Mme. Le Gras, a pious and charitable lady. The object of this institution was the care of the poor, especially of the sick, and the education of children; and its members are everywhere the servants of the poor, which name was conferred on them by the archbishop of Paris when he gave them his formal approbation in 1655. Prisons, free schools, hospitals, and almshouses were at once placed under their direction in all parts of France. The congregation was soon invited to take charge of similar institutions in other countries, and the sisters of charity are now to be found in almost every civilized land. Louis XIV. granted letters patent to this institution in 1657, and they were finally confirmed by the legate of the pope in 1660. The charity and devotion of these women had made them so useful to all classes, that even the revolution spared them. They continued their work of beneficence secretly, but without restraint. One of the first acts of the new government was to open to them a field of usefulness, and Napoleon placed them under the protection of his mother. They make simple vows, which are renewed every year. In 1862 the number of establishments was 1,064, viz.: 947 in Europe, 80 in America, 17 in Asia, 17 in Africa, and 3 in Australia and Oceania. The number of members was estimated at 28,000. The American branch of this congregation was established at Emmitsburg, Md., in 1809, by Mrs. Eliza Seton, their first mother superior. The foundation of Mrs. Seton until within a few years remained a quite distinct establishment from the French order; but of late a great portion of the American sisters of charity have adopted the French dress and rule. The New York mother house and its dependencies, however, still retain their original independence. In 1873 there were in the United States 156 houses belonging to the sisters of charity.

CHARIVARI (Fr. *charivari*; Ger. *Katzenmusik*; Sp. *concejada*; It. *scampanata*), a mock serenade, which was performed in the middle ages whenever an old man married a young girl, or when a man married for the second or third time, or generally when ill-assorted marriages took place. The neighbors assembled on such occasions during the night before the house of the wedded pair, with all sorts of pans and kettles, and iron and copper utensils (*chalybaria*), producing every variety of discordant noises, and accompanying them with derisive shouts and songs. The charivariists usually continued their uproar until their wrath was soothed by drink or food. The council of Trent attempted to put a stop to this nuisance, which frequently occasioned disturbances. In some French towns, as for instance in Lyons, the practice was maintained as late as the 16th century. In Canada, and in Louisiana and many other parts of the United States, it exists, though it is everywhere on the decline. In Brittany the term charivari was also applied to aggravated collisions between husband and wife. Xantippe throwing a jug of water at the head of Socrates is the most classic type of this sort. In the game of ombre the turn of four queens is called charivari. The Germans possess a work on the origin of *Katzenmusik* by Philipps (Freiburg, 1849). French literature boasts of a still more comprehensive work on the same subject: *Histoire, morale, civile, politique et littéraire, du charivari, depuis son origine vers le 4me siècle*, by Dr. Calybariat de St. Flour, with a supplement by Eldi Christophe Bassinet.

CHARLEMAGNE, Emperor of the West. See CHARLES I. (GERMANY).

CHARLEMONT. See GIVET.

CHARLEROI, or *Charleroy*, a town of Belgium, in the province of Hainaut, situated on the Sambre, and connected by railroads with Brussels, Namur, and Paris, 28 m. S. of Brussels; pop. in 1866, 12,150. The glass works here are the most extensive in Belgium. The annual yield of the collieries in the vicinity is estimated at 3,000,000 cwt. There are about 6,000 nail makers in the adjoining country, and 70 blast furnaces, 50 iron founderies, and 90 coal pits, almost all of which have sprung into existence within the last 50 years. There are also tanneries, dyeing establishments, ropewalks, salt and sugar refineries, and factories for spinning wool. It is the chief seat of the Protestant missions in Belgium, and has had a Protestant church since 1850. The fortress was commenced under Charles II. of Spain in 1666, and completed by Vauban for Louis XIV. It is a hexagon, with five counterscarps, two hornworks, and five ravelins. It has changed masters several times, and in 1794 stood a vigorous siege, and held out until all the advanced works were levelled with the ground, and until four assaults had been made by the French, when it capitulated. It was restored in 1816 under the direction of the duke of Wellington.

CHARLES, a S. W. county of Maryland, separated from Virginia by the Potomac river, and bounded N. E. by the Patuxent; area, 450 sq. m.; pop. in 1870, 15,738, of whom 9,318 were colored. The surface is uneven and the soil rather inferior. The forests consist mainly of oak, chestnut, ash, cedar, and locust. The chief productions in 1870 were 73,028 bushels of wheat, 221,726 of Indian corn, 50,813 of oats, 987 tons of hay, 53,878 lbs. of butter, 11,428 of wool, and 2,102,739 of tobacco. There were 2,004 horses, 1,676 milch cows, 4,960 other cattle, 3,872 sheep, and 6,978 swine. Capital, Port Tobacco.

CHARLES. The more important sovereigns of this name will be treated according to the alphabetical order of the countries over which they ruled, viz.: 1, England; 2, France; 3, Germany; 4, Naples; 5, Sardinia; 6, Savoy; 7, Spain; 8, Sweden; 9, Würtemberg. These are followed by minor princes of the name, sovereign and non-sovereign.

I. ENGLAND.

CHARLES I., the second of the house of Stuart who sat on the English throne, third son of James VI. of Scotland and I. of England, and Anne, daughter of Frederick II. of Denmark, born at Dunfermline, Fifeshire, Scotland, Nov. 19, 1600, executed in London, Jan. 30, 1649. He became heir apparent to the crown of England on the death of his elder brother, Prince Henry, in 1612, was created prince of Wales in 1616, and succeeded his father as king in 1625. He early fell under the influence of his father's favorite, the duke of Buckingham, and in 1623 went with him secretly to Madrid, to confirm his marriage contract with the Spanish infanta. They travelled under the names of John and Thomas Smith, and arrived at the house of the earl of Bristol, the English ambassador, on the evening of March 7. They spent some months in Madrid, but the marriage, which was hateful to the people of England, appears not really to have been desired by Charles; and when he left, Sept. 9, the marriage articles, although formally confirmed, were in fact set aside, Buckingham being resolute against them, while the prince probably agreed with his companion. This early enterprise was most unfortunate, as being a beginning of that course of dissimulation and insincerity which was the great defect of Charles's whole career. There was great joy in England that the match was broken off. Buckingham assumed the credit of the deed, but soon arranged a marriage with the princess Henrietta Maria, daughter of Henry IV. of France and his second wife, Maria de' Medici, at least as great concessions being made to the English Catholics, in order to gratify the French king Louis XIII., and his minister Richelieu, as had been demanded by the court of Spain, against which war was simultaneously declared. James I. died, however, before the marriage was even ratified. But on March 30, 1625, three days

after the accession of Charles, the ratification took place, and after the lapse of about three months, during which delays occurred owing to the illness of Louis, the queen was received by Charles at Dover, formally married by him at Canterbury, and installed at Hampton court, the entrance of the royal party into the metropolis being prevented by the ravages of a terrible pestilence, said to be the most destructive within the memory of man. The marriage itself was inauspicious; all its influences, both social and political, were of evil consequence to both king and kingdom; and the wife of Buckingham's bestowal was, to say the least, as fatal to the prospects of Charles as were the teachings and example of that minister, and the animosity excited against the crown, among the commons, by his baseness. Charles I. had education, some accomplishments, and a calm, grave demeanor. He had, moreover, a personal purity of morals and dignity of virtue which gave a new tone to the court upon his accession. But he lacked quickness of perception, and was very hard to convince or persuade; while his age was an age of transition, when new ideas were working, and new issues arising, demanding the most original as well as the most firm statesmanship. James had continually talked about his royal prerogative. Charles tried consistently to establish and maintain the ideas of which his father had been content merely to talk. To the end of his life he adhered steadily to the autocratic notions with which he began. On the other hand, he had learned to dissemble; dissimulation was what his father had called "kingcraft;" and Charles continually sought to secure power by this means, and to one supposing his concessions to his people sincere he appears weak and vacillating. His public course was changeful and fickle, but his letters to his queen and confidants reveal his duplicity, and his consistency to his first idea. His first parliament met June 18, 1625. It was not lavish in granting supplies, and was dissolved Aug. 12, and the king levied taxes and raised loans by his own authority, to carry on the war against Spain. On Feb. 6, 1626, a second parliament met, and was as unready to vote money as the first. It also impeached Buckingham, whose unpopularity was now great. Charles dissolved the parliament, imprisoned some of the leaders of the opposition, and then raised money again by his own authority. He also billeted soldiers on the people and proclaimed martial law in places. Although already at war with Spain, he plunged into another war with France, and tried to carry on both by forced loans and other illegal expedients. But all expedients were inadequate, and he was at length forced to call a third parliament, which met March 17, 1628. In this body the opposition was stronger than ever, and framed a "petition of right," which claimed that the king should not levy taxes except with the concurrence of parliament, nor subject the people to trials by courts martial, nor im-

prison any subject without due process of law. Upon his assent to this was conditioned any grant of money. Charles at length agreed to the petition, and there was great rejoicing among the people; but after getting the money voted, he imprisoned Eliot and other distinguished members of the house of commons. In the mean time the English arms were covered with disgrace; yet still the king persisted in retaining Buckingham at the head both of his councils and of his army, and that favorite was on the point of again setting sail from Portsmouth at the head of an expedition to the coast of France, when he was assassinated by a man named Felton. The expedition sailed under another commander, but was too late and too inefficient to relieve La Rochelle, which, after having had the most positive assurances of relief from Charles, and after incredible sufferings, was obliged to surrender. Parliament reassembled, after its recess, Jan. 26, 1629, but gave little comfort to the king, and on March 10 he dissolved it, with such expressions as were understood to preclude the assembling of another; and from this time till April, 1640, he tried to rule without a parliament. Upon the dissolution of parliament in 1629, Wentworth, afterward Lord Strafford, who had been one of the opposition leaders, attached himself to the king. He was a man of great ability, but of unscrupulous character. He resolved to make Charles in fact the absolute monarch which he claimed to be, and he saw that the means to this end was a standing army. At the same time the ecclesiastical government of England was confided to Laud, who was made archbishop of Canterbury. Charles was a devoted churchman, and made as much of Laud's ecclesiastical work as of Wentworth's political schemes. It is doubtful whether the nation would not have submitted to Wentworth and endured a military despotism, had not the religious tyranny of Laud goaded the people into rebellion. Wentworth revived the court of the star chamber, and organized the council of York, by which the whole administration of justice was put under arbitrary control, while the high commission exercised a similar tyranny in ecclesiastical matters. The king raised "ship money," and Hampden and others who resisted the illegal tax could get no redress. By the extreme high church assumptions of Laud, the Puritans of England were led to believe that Charles and his primate were bent on reintroducing the ancient worship of the Roman Catholic church; and although the suspicion was not true, yet, knowing that it existed, none are to be blamed but they for persisting in a course of conduct which could but aggravate and confirm it. Ireland, in the mean time, by the oppressive government of Wentworth, whose only object was to raise money in order to meet his master's exigencies without resorting to the aid of parliament, was driven to the verge of rebellion. Scotland, maddened by the king's attempt, at the instiga-

tion of Laud, to force episcopacy upon her contrary to the fundamental law of the kingdom, rose in arms, invaded England, and gained possession of Northumberland and Durham. The king made a fruitless attempt to raise funds to oppose the Scottish armies by summoning a parliament, but which, as it proceeded, like the last, first to consider grievances, he dissolved on May 5, 1640, within 20 days after its assembling, before it had given any positive reply to his demand for supplies. Tyranny in church and state was now at its worst. Torture was inflicted for the last time in May, 1640. At this time Charles had a fleet of above 60 ships at sea, which he maintained by the illegal levy of ship money; but he had no army on which he could depend, nor any means to raise one. Therefore, unless he would see the Scots march to York and take possession of the northern metropolis, there was no resource but to convoke the great council of the peers at York, who immediately demanded the assembling of the parliament, and to treat with the Scottish rebels. On Nov. 3, 1640, assembled the body known in history as the long parliament. Its first act was to impeach and then to proceed by attainder against both Laud and Strafford, the latter of whom was condemned and executed, abandoned by the king, for whom he had made great sacrifices. Some just and salutary laws were passed by this parliament; some illegal practices, which had been usual with the later English monarchs, were repressed; some grievances redressed; some rights of the subject firmly established. It also passed a bill that it should not be dissolved except with its own consent. This act was plainly unconstitutional, but was approved by the king. The star chamber and high commission were abolished, and on Dec. 31, 1641, the house voted to consider on Jan. 3 the question of the militia. On Jan. 2 the king sent his refusal to the commons to appoint a guard for their security, but promised solemnly, on his word as a king, that their security should be his sacred care; but the next day his attorney general appeared at the bar of the house of lords, and in the king's name accused of high treason Lord Kimbolton and five members of the commons, Pym, Hollis, Hampden, Haslerig, and Strode. These were accused of endeavoring to subvert the fundamental law and deprive the king of his regal power, of alienating his subjects and army, of encouraging foreign invasion, and conspiring to levy war against him. These charges were for the most part aimed against their parliamentary conduct. The king demanded their arrest, and the next day came to the house in person to arrest them by armed force; but the five members had absented themselves by permission of the house. The excitement in parliament and in the city was unparalleled. Some of the king's partisans wished to seize the six members, who were known to be in a house in Coleman street; but the king chose to de-

mand them of the common council, and on the 8th he issued a proclamation for their arrest. The manifest unpopularity of his cause made his friends fear for his personal safety, and on Jan. 10 he left Whitehall for Hampton court. The next week the accused members were brought back with the enthusiasm of a popular triumph, and the rupture between the king and his parliament seemed complete. Parliament passed a militia act, which amounted to an army act, and Charles sent his queen to Holland Feb. 16, 1642, with the crown jewels, to raise troops against the parliament. On April 23 the king virtually began the war by trying to force an entrance into the city of Hull. The military governor, Hotham, kept him out, and was approved by parliament. The royalist members of parliament vacated their seats, and repaired to the king. The rest no longer tried to pass acts for the king's approval, but passed "ordinances." On May 5 was passed an ordinance calling out the militia. Charles proclaimed this ordinance illegal and summoned the gentlemen of York to form his body guard. He made an address to an assembly of gentlemen in the town hall, which was received with applause; but the attempt to form a body guard was a failure. Another great meeting, 40,000 strong, was held on the moor without the town, where a petition was presented to the king asking him to be reconciled to his parliament, which he received with undisguised displeasure. Parliament now prepared for war. They proposed terms to the king which they knew he would refuse. On July 12 they voted to raise an army. On Aug. 22, Prince Rupert having joined the king, the royal standard was set up upon Nottingham castle. On Sept. 9 parliament published a declaration of the causes of the war; and on the 19th the king issued his "protestation," promising to respect the freedom of parliament, and declaring his purposes. Unhappily his private letters to the queen show that his professions were insincere. On Oct. 23 was fought the first battle at Edgehill, with alternating success, and without decided advantage to either side. Essex, the commander of the parliamentarians, was the first to withdraw on the following morning, unpursued by the enemy. On Feb. 22, 1643, the queen landed with an army. Prince Rupert carried many small places through the spring and summer. Hampden was shot in a skirmish. Bristol surrendered to Rupert, July 25, and the parliamentary cause seemed weak and discouraged. Had the royalists now been united and prompt, they might have triumphed and utterly overthrown the popular party. They feared, however, to trust the king, and the battle of Newbury, Sept. 20, was a stubborn fight, and took away all hope of a speedy peace. The remodelling of the parliamentary army followed. Cromwell and Fairfax became its generals; and a discipline was introduced by the former as perfect as that of

any modern service, and a spirit of religious enthusiasm which equalled or surpassed the enthusiastic loyalty and chivalry of the cavaliers. The new discipline proved its power in the battles which followed. An important battle was fought at Marston moor, July 2, 1644; and at Naseby, June 14, 1645, the royal cause was totally overthrown, and the royal army dissipated. After some attempts at negotiation, marked by his usual insincerity and chicane, with the leaders of the parliament and of the army, neither of whom he chose to trust, while neither dared to trust him, Charles delivered himself up to the Scots, May 5, 1646, who, on Jan. 30, 1647, gave him up to the commissioners of the English parliament. Cromwell, who as yet entertained no definite views, was prepared to play the part subsequently played by Monk; and Fairfax, who was averse to all extreme courses, was ready to support him. Yet, even now, when terms were offered him by the Independents so advantageous that Sir John Berkeley, one of his trustiest adherents, declared that "a crown so near lost was never yet so easily recovered as this would be, were things adjusted on these terms," the king refused to concede anything, broke off all terms with the army, commenced new negotiations with the Presbyterians, and ultimately convinced all parties that there was no truth in him. The discovery of a fatal letter to his wife, in which he assured her that he designed for those rogues, Ireton and Cromwell, no reward but that "for a silken garter they should be fitted with a hempen rope," destroyed him. From that moment the chiefs of the army saw that the question lay between their own lives and his life, and they of course decided that it should not be their own, if they could help it. Having been taken on June 4 by Cornet Joyce out of the hands of the commissioners and brought to the army, then lying at Triploah heath, and now in open rebellion against the parliament, he was taken on Aug. 16 to Hampton court, from which he escaped on Nov. 11, eventually seeking refuge with Hammond, the parliamentary governor of the Isle of Wight. Here he was imprisoned in Carisbrooke castle till Nov. 30, 1648, when, by an order of the council of officers in the army, he was removed to Hurst castle, on the opposite coast of Hampshire. The now dominant army promptly suppressed all risings in his favor. A force in the Presbyterian interest, under the duke of Hamilton, was routed by Cromwell at Langdale, near Preston, Aug. 17. On Dec. 6 the house of commons was invaded by Col. Pride, with a strong detachment of soldiers, and all members ejected except about 150, who were in the Independent interest. On Dec. 22 Charles was brought in custody to Windsor, and on Jan. 15, 1649, to St. James's. On Jan. 20 he was brought to trial in Westminster hall, before a high court of justice specially organized for the purpose. Sentence of death was passed upon him, Jan. 27, and he

was executed by decapitation on a scaffold erected in front of the banqueting house at Whitehall.—Charles I. had eight children by Queen Henrietta, six of whom survived him, viz.: Charles and James, afterward kings of England; Henry, duke of Gloucester; Mary, the wife of William, prince of Orange, and the mother of William III. king of England; Elizabeth, born in 1635, who died a prisoner in Carisbrooke castle Sept. 8, 1650; and Henrietta Maria, the wife of Philip, duke of Orleans, from whom, through a daughter, is descended the royal family of Italy. Charles was an elegant writer of English, and in the early part of his reign a zealous patron of the fine arts. The writings attributed to him are indicated in Horace Walpole's "Royal and Noble Authors," and have been published under the title of *Reliquiæ Sacræ Carolinæ*. Among them is the famous work, the *Etikon Basilike*, or "Portraiture of his Sacred Majesty in his Solitudes and Sufferings;" his claim to its authorship, however, has been much disputed.

CHARLES II., second son of the preceding (the first son, Charles James, having died on the day of his birth, March 18, 1629), born May 29, 1630, died Feb. 6, 1685. At 12 years of age he was appointed by his father commander of the troop of horse which he raised as a body guard at York, and three years afterward he was sent to serve with the royal troops in the west with the rank of general. After the battle of Naseby (1645) the prince retired to Scilly, and subsequently to Jersey, where he remained till September, 1646, when he joined his mother in Paris. In 1649, while residing at the Hague, he received the news of the execution of his father, and immediately assumed the title of king, and was proclaimed king in Edinburgh Feb. 3, 1649, but with little prospect of ascending the throne. Having left Holland to spend some time in Paris, he subsequently repaired to Jersey, whence he arrived in the north of Scotland June 23, 1650, after having agreed to the conditions imposed by the Presbyterians, and after having been forced to take the covenant before landing. Proclaimed king of Scotland at Edinburgh, July 15, 1650, he was crowned at Scone, Jan. 1, 1651. Cromwell, however, having already conquered the greater part of Scotland, Charles resolved on marching to the south, entered England Aug. 6, and took possession of the city of Carlisle, where he was again proclaimed king. The battle of Worcester (Sept. 3), however, in which he was defeated by Cromwell, put an end to this enterprise. After many narrow escapes from capture, he succeeded in embarking at Shoreham, Sussex, Oct. 15, and went to Normandy, and thence to Paris. The peace of 1655 forcing him to leave France, he went to Bruges and remained there and in Brussels until the news of Cromwell's death in 1658 reached him. In order to be able to avail himself of the confusion which arose in Eng-

land after the downfall of Richard Cromwell's government, Charles stationed himself at Calais in August, 1659; but it was not till April, 1660, that he succeeded during his stay at Breda in opening a negotiation with Gen. Monk. Having transmitted to parliament a document called the declaration of Breda, containing specific pledges as to his future conduct and principles of government, his restoration to the throne of England was voted on May 1, and on May 8 he was proclaimed king in London, which city he entered May 29, having departed from the Hague six days before. His journey to London was one continued triumph; and the whole of the country through which it passed bore the aspect of a universal fair day. So great was the rapture of loyalty with which Charles was received, that, with his usual wit, he observed to some one of his company that he could not see for the life of him why he had stayed away so long, when everybody seemed so charmed that he was at length come back. He was received with open arms, and reinstated without being asked to give a guarantee or to make a concession. In the general joy at the restoration, many acts were popular, or not unpopular, which at another time would have caused great indignation. There was little general excitement when the Presbyterian ministers were ejected from their livings in August, 1662. The first really unpopular acts of the king were his declaration of indulgence to Catholics, and the surrender of Dunkirk, toward the close of 1662. This fortress, won by the valor of the Cromwellian soldiery, which was regarded as a compensation for the loss of Calais, was ignominiously sold to the French. The declaration of Breda had left the question of church lands which had been sold during the protectorate to be settled by parliament; but by the management of Clarendon parliament adjourned without settling it, and the result was the vitiating of all such sales and the entire restoration of the lands, the buyers having no redress in the courts. The king had made the most general promises of pardon and amnesty, and even the regicide judges were invited to trust to his honorable clemency; but with the concurrence of parliament, and in truth by act of parliament, they were excepted from the indemnity, even those who surrendered themselves, and all but a few who escaped were either imprisoned for life, or hanged, drawn, and quartered. By vote of the commons, the bodies of Cromwell, Bradshaw, and Ireton were disinterred, and hanged upon the gibbet at Tyburn. The duke of Argyll was executed in Scotland, and Sir Henry Vane in England; and the excessive zeal for episcopacy of Clarendon and the rough cruelty of Claverhouse made this a reign of bitter religious persecution. The more moderate Presbyterians, led by Baxter, were persuaded at first that the king would be friendly to them, but were bitterly undeceived. On May 20, 1662, Charles was married to Catharine of

Braganza, daughter of John IV. of Portugal, a virtuous and amiable princess; but he soon outraged her by presenting to her his avowed mistress. The poor queen fainted and the blood gushed from her nose, but Clarendon at length persuaded her to submit to the insult, and her spirit was utterly broken. The unblushing licentiousness of the court was a scandal to the world, even in that day of reaction against Puritan severity. Its excessive extravagance so far exceeded even the liberal grants made by parliament for the royal expenses, that there was general wonder and inquiry where the money was obtained; and in 1664 there was so much gossip in the London coffee houses about money from France, that some of these were closed by order of the government as places of treasonable talk. War broke out with Holland in February, 1665, followed by rupture with France; while parliament continued to legislate against religious nonconformists. In the summer of this year London was desolated with the plague; and in September, 1666, a terrible conflagration completed the work of destruction. The war with the Dutch brought little glory, and in 1667 their ships broke into the Medway and blockaded the Thames. On July 31 a treaty of peace was concluded at Breda. This was followed by the dismissal of Clarendon, through the intrigues, it is believed, of the king's mistress. He was followed after a short interval by the ministry known as the Cabal. In January, 1668, Sir William Temple effected the triple alliance between England, Holland, and Sweden. The king announced this to parliament, and it gave great satisfaction to the nation, being in truth the best public act since the restoration. Unhappily, at this very time, he was negotiating a clandestine treaty with Louis XIV., which was to make England wholly subservient to the French king; and when Sir William came home in the autumn of 1670, he was coldly received by the ministers and king, and retired from public life. To supply money to the king and ministry, the exchequer was closed, and the regular payments of over a million pounds then due were suspended by proclamation for a year. A financial panic and great distress ensued. It was decided to capture a fleet of Dutch ships, but the Dutch convoy beat off the English admiral. On March 17, 1672, war was declared against Holland, and a declaration from France was issued at the same time. The pretexts for war were trifling. The first important battle, in Southwold bay, May 28, gave little advantage to either side. The French meantime were victorious on land. But the young prince of Orange proved the deliverer of his country. The war dragged on for two years, when a separate peace was made between England and Holland, the war on the part of France still continuing. Meantime Charles made a declaration of indulgence in religion, suspending all penal laws in religious matters, in consequence of which many prison-

ers were released; among others John Bunyan, who had been in jail 12 years. This declaration, however, was extremely unpopular. Parliament on Oct. 20, 1673, petitioned against the proposed marriage of the duke of York with the princess of Modena, but Charles replied that the alliance was already completed. Parliament was disposed to remonstrate against the alliance with France, and against the king's evil counsellors. For the next seven years the king and parliament were in a continual contest, the court being utterly corrupt and parliament exceedingly factious. The subserviency of Charles to Louis XIV. was most shameful. The long prorogation of parliament in November, 1675, was an arrangement with the French king, for which Charles received 500,000 crowns. The two kings agreed to make no treaties not mutually acceptable, and Charles accepted a pension, upon his pledge to prorogue or dissolve any parliament which should attempt to force such treaties upon him. Prince William of Orange came to England in 1677, and was married, Nov. 4, to the princess Mary, daughter of the duke of York. This gave offence to Louis, and he stopped Charles's pension. There was great public discontent at the conversion of the duke of York to the Roman Catholic faith, and his marriage to a Catholic princess, and the whole nation was excited over the supposed discovery of a popish plot to assassinate the king. The investigation of this plot dragged along for years, and resulted in the imprisonment and death of many eminent persons; but nothing of importance was discovered, and it was common for each political party to charge its opponents with the invention of the plot. While this excitement was still high, the secret treaty with Louis XIV. was revealed, and parliament impeached the lord treasurer Danby, who suffered for the crimes of which he was only an accomplice. Charles interrupted these proceedings by proroguing parliament, Dec. 21, 1678, and dissolving it, Jan. 24, 1679. The new parliament met March 6, and did one noble deed in passing the habeas corpus act, which Charles signed May 26. A bill for the exclusion of the duke of York from the succession to the throne passed a second reading in the commons, when parliament was prorogued on May 26 to Aug. 14, and before its reassembling dissolved. On Nov. 15 the next house of commons passed the bill, but it was rejected by the house of lords. In 1683 the discovery of the Rye House plot led to the arrest of a number of eminent whig leaders upon suspicion of complicity. There seems to have been a real plot among some obscure persons, but the complicity of these leaders was not believed even by the royalists of the time; yet Lord William Russell was beheaded July 21, Algernon Sidney Dec. 7, and Sir Thomas Armstrong June 20, 1684. The duke of York was now closely associated with the king, and openly succeeded to the chief administration of public affairs.

He had consented to the marriage of his daughter Anne with the Protestant Prince George of Denmark, and was restored to his offices of high admiral and privy councillor. Arbitrary government was unchecked in England, while abroad the nation counted for nothing. Even some of Charles's advisers felt the national degradation. Halifax suggested the calling of a parliament, and opposed the French alliance. The duke of York opposed him. While this discussion was unsettled, the king was struck with apoplexy. When it was plain that he was dying, the duchess of Portsmouth told Barillon, the French ambassador, that Charles was really a Roman Catholic, and was dying outside the pale of his church. Barillon told the duke of York, and James, conferring with his brother, at his desire brought him a priest, and Charles confessed and received extreme unction.—Charles had good natural abilities and an amiable temperament. His early education and misfortunes quickened his wit, but left him careless of duty, incapable of self-denial, and skeptical of all virtue. He knew the worthlessness of his favorites, but was their slave, though not their dupe. He was lavish of money, but not generously so, giving to those who pressed him hardest. His political course was not from motives of principle and conviction, as his father's had been, but he wished to be a king after the French fashion, unhampered by lack of money or constitutional obstacles in the pursuit of his personal wishes. He was devoid of revenge as well as of gratitude, and treated friends and enemies with the same indolent selfishness. His affability, however, made him to some extent popular, in spite of his gross defects of character and disgraceful misgovernment.—Charles had no children by his queen. Among his natural children were: 1, James, duke of Monmouth, by Mrs. Lucy Walters, born at Rotterdam in 1649, ancestor of the dukes of Buccleugh; 2, Mary, also by Mrs. Walters; 3, Charlotte Jemima Henrietta Maria Boyle (alias Fitzroy), by Elizabeth Viscountess Shannon; 4, Charles, surnamed Fitz-Charles, by Mrs. Catharine Peg; 5, a daughter by Mrs. Peg, who died in infancy; 6, Charles Fitzroy, duke of Southampton, by the duchess of Cleveland; 7, Henry Fitzroy, duke of Grafton, by the same, ancestor of the dukes of Grafton; 8, George Fitzroy, duke of Northumberland, by the same; 9, Charlotte Fitzroy, by the same; 10, Charles Beauclerc, duke of St. Albans, by the famous Nell Gwynn, ancestor of the dukes of St. Albans; 11, Charles Lenox, duke of Richmond, by Louise Quérouaille, a French woman, created duchess of Portsmouth, ancestor of the dukes of Richmond; and 12, Mary Tudor, by Mrs. Mary Davis.—See Bishop Burnett's "History of His Own Time;" Evelyn's "Diary and Correspondence;" Samuel Pepys's "Diary and Correspondence;" Gramont's "Mémoires," by Hamilton; and Jesse's "Court of the Stuarts."

II. FRANCE.

CHARLES MARTEL, duke of Austrasia and mayor of the palace of the Frankish kings, born about 690, died in 741. He was the natural son of Pepin of Héristal, by his mistress Alpaïda, and seemed at first doomed to an inferior rank on account of his illegitimate birth, as well as the dislike shown to him by his father and the hatred of Plectruda, his father's lawful wife. The second son of the latter, Grimoald, having been assassinated at Liège, Charles was charged with being the murderer and consequently thrown into a dungeon, while Plectruda was intrusted with the government and the guardianship of her grandson, who, although still a child, had been declared mayor of the palace of the young king Dagobert III. The Franks were thus ruled by a woman in the name of two children. This could not be endured; and the Neustrians first rebelled against Plectruda, and the Austrasians liberated Charles from prison, and proclaimed him their duke. Under his command they invaded Neustria, gained several victories, and obliged their western brothers to acknowledge the authority of their leader. Thus Charles became sole lord of both kingdoms, permitting however the nominal reign of Dagobert III., Chilperic II., Clotaire IV., and Thierry IV. to continue to 737. But on the death of the last named Charles appointed no successor and retained the supreme power, although not assuming any higher title than that of duke of the Franks. His energetic government at home caused the powerful Austrasian aristocracy to submit, as well as the prelates of Neustria and Burgundy, while his valor enlarged the extent of the Frankish kingdom. He waged successful wars against several German nations; but his brightest laurel was won in his struggle with the Moslems, who after the conquest of Spain had crossed the Pyrenees and attempted to conquer Gaul also. The southern part of this country had been first successfully protected by the gallant Eudes, duke of Aquitania, who had even routed the Moslems in 721 in a great battle under the walls of Toulouse; but, overpowered by the immense forces of the invaders, he was eventually compelled to call upon the duke of the Franks for assistance. The Moslems had already penetrated as far as Poitiers, when Charles at the head of his Frankish and German warriors met them a few miles N. E. of that city. Both armies stopped and passed six days in desultory skirmishes before engaging in a decisive battle. At last, on Oct. 3, 732, the Christian infantry received the charge of the Arabian cavalry, and withstood unbroken its repeated assaults, until at sunset the Saracens retired to their camp. In the confusion and despair of the night the various tribes of the Orient, Africa, and Spain were provoked to attack each other, and the remains of the host were suddenly dissolved, every emir seeking safety by a precipitate

flight. At sunrise the Franks, to their unbounded astonishment, perceived that the enemy had left their camp and were retreating in haste toward the south. The Moslems had not dared to renew the battle. This victory, which took place 100 years after the death of Mohammed, checked the power of his adherents and saved western Europe from their further invasions. Charles, from his conduct on this great occasion and the vigor of his arm, received the surname of Martel, "hammer." His prudence prevented him from pursuing the retreating army; but he subsequently renewed the war, and forced the Arabian emirs who had maintained their power over several cities of southern Gaul to return to Spain. The whole of Aquitania was annexed to the Frankish empire, which was ruled by Charles, and after his death divided between his two sons, Austrasia being given to Carloman and Neustria to Pepin. The latter soon became possessed of the whole, and afterward assumed the title of king, the first of the Carolingian dynasty.

CHARLES I. (CHARLEMAGNE). See **CHARLES I. OF GERMANY.**

CHARLES II., the Bald, the fourth king of the Carolingian dynasty, born at Frankfort-on-the-Main in 823, died in a village at the foot of Mont Cenis in October, 877. The son of Louis le Débonnaire by his second wife, Judith of Bavaria, his birth gave rise to serious troubles between his father and his elder brothers. War followed, in which the old Louis le Débonnaire was harshly dealt with by his sons; and his death, June 20, 840, found Charles holding nearly the whole western part of the empire. His claim being, however, disputed by his eldest brother Lothaire, who had assumed the imperial dignity, Charles, to maintain his rights, formed with his second brother Louis, king of Bavaria, an aggressive alliance against the emperor, and defeated him in a desperate battle fought June 25, 841, at Fontenay or Fontanet, in Burgundy. The victory, however, weakened their resources to such an extent as to prevent them from following it up. Charles and Louis renewed their alliance in a solemn meeting at Strasburg, Charles taking an oath in the German language, and Louis in the vernacular of the people of Gaul. The words of this oath, which have been preserved, are the first monument of the Romance language, from which the French has sprung. The union of Charles and Louis brought Lothaire to terms; and the treaty of Verdun in 843 secured to the former the tenure of his kingdom, that is, the whole of Gaul W. of the Meuse, the Saône, and the Rhône, which henceforth was to be called France, and part of Spain N. of the Ebro. But the submission of all the provinces of this kingdom was far from being complete, and Charles had frequently to resort to arms against the people of Brittany and Aquitaine. Under his reign the Normans, who had previously desolated the coasts of Gaul, invaded the country by ascending the

rivers, burning and plundering the villages and the cities. Paris itself had to suffer by their ravages, Charles being unable to afford protection against them. On the death of his nephew, the emperor Louis II., in 875, Charles seized upon the imperial crown; but his power seems to have been rather diminished by this assumption of a new title. A few months later he was compelled to sign a decree by which the tenure of the counties was declared hereditary, which decree was the foundation of the feudal system in France. This was the last important act of his otherwise inglorious reign.

CHARLES THE FAT. See CHARLES THE FAT, Germany.

CHARLES III., the Simple, the eighth king of the Carolingian dynasty, born Sept. 17, 879, died at Péronne, Oct. 7, 929. A posthumous son of Louis the Stammerer, he was excluded from the throne first by his brothers, then by Charles the Fat of Germany, and finally by the election of Eudes. As soon, however, as he became of age, he asserted his claim to the crown, sought for the protection of the Carolingian princes of Germany, and was in 898 recognized as king by the majority of the French nation. Being unable to resist the incessant aggressions of the Normans, he concluded a treaty with their chief Rollo, at St. Clair-sur-Epte, in 911, by which he bestowed upon him as a duchy the whole N. W. part of Neustria, also giving him his sister in marriage. For a few years France enjoyed comparative quiet, but in 922 the barons revolted against the narrow-minded Charles, and elected as king Robert, the brother of Eudes. Charles defeated his rival, and killed him with his own hand; but he was in his turn defeated by the son of Robert, Hugh the Great, count of Paris; and having sought a refuge with Herbert, count of Vermandois, he was detained by him as prisoner until his death. The party which opposed the Carolingians then reigned paramount, and it was not till 936 that Louis IV. d'Outremer, the son of Charles, became king.

CHARLES IV., the Fair, the last king of the direct line of the Capetian dynasty, born in 1294, died at Vincennes, Jan. 31, 1328. The third son of Philip IV., the Fair, he succeeded his brother Philip V., the Tall, in 1322, and visited with severe punishment the Lombard money-changers for their many extortions, the judges for their prevarications, and the barons for their unlawful encroachments upon private property. He secretly aided his sister Isabella in her revolt against her husband, Edward II. of England, made a futile attempt to be elected emperor of Germany, and died leaving his third wife, Jeanne d'Évreux, pregnant. On her being delivered of a daughter, the crown went to Philip of Valois, the cousin of Charles, and the grandson of Philip III., the Bold. The Capetian direct line ended by three brothers succeeding each other: Louis X., Philip V., and Charles IV.; so did the collateral branches of Valois and Bourbon.

CHARLES V., the Wise, the third king of the family of Valois, son of John II., born Jan. 21, 1337, died at Vincennes, Sept. 16, 1380. He was a prince of very little military genius, but with much taste for learning. Being in command of a body of the French army at the battle of Poitiers, he deserted the field at an early period, while his father and younger brother fought bravely. On the captivity of the former (1356), he was appointed his lieutenant, and had to contend against a formidable popular rebellion, headed by Stephen Marcel, provost of the merchants of Paris, and Robert Le-coq, bishop of Laon. At length, after having succeeded in getting rid of the principal leader, who was murdered by one of his adherents, he assumed the title of regent, and concluded in 1360, with the English, the treaty of Brétigny for the liberation of the king. By this treaty, Edward III. was to remain in independent possession of all the provinces of the Loire, comprised under the general name of Aquitaine, with Ponthieu and the country around Calais; but he was to renounce his claims to the crown of France, as well as those to Normandy, Touraine, Anjou, Maine, Brittany, and Flanders; the ransom of John was fixed at 3,000,000 gold crowns, while two of his sons and several great lords of the kingdom were to be given as hostages. John was liberated; but the terms of his liberation not having been complied with, he returned to England, leaving for the second time the regency in the hands of Charles, who succeeded him on his death in 1364. Charles was now at full liberty to display the shrewdness of his policy, and soon worsted Edward III., who had defeated both his father and grandfather. Being greatly assisted by the valor and prudence of his great constable Du Guesclin, he destroyed several armies of the English, and wrested from them the French provinces which they had held for years. On the death of Edward, the only places still left in their hands were Bordeaux, Bayonne, Cherbourg, Calais, and a few other fortresses. By timely assistance to Henry of Trastamare against Pedro the Cruel, king of Castile, Charles had secured for himself an ally who was of great service in his naval contests, and consequently instrumental in his final success over England. Meanwhile, tranquillity, order, and prosperity had been restored to France; and several important learned institutions were founded, among the number the king's library, now the great national library in Paris. In his reign the Bastille was also erected, mainly with a view to hold the Parisians in submission. Charles V. was, if not one of the greatest, at least one of the most useful of French kings.

CHARLES VI., the Mad, or the Beloved, the fourth king of the family of Valois, born in Paris, Dec. 3, 1368, died Oct. 21, 1422. The son of Charles the Wise, he was but 11 years old when his father died; and his uncles, the dukes of Anjou, Berry, Burgundy, and Bour-

bon, undertook to reign in his name. A general rebellion broke out against their oppressive administration, especially in Paris, where the insurgents were called *Maillotins*, from the mallets with which they were armed. Charles was taken by the duke of Burgundy to Flanders, and won, Nov. 27, 1382, the battle of Roosebeke. This success resulted in the temporary submission of the great cities of France. The king's uncles availed themselves of this opportunity to levy new taxes upon the people, but Charles dismissed them in 1388, declaring that he intended to govern for himself; and for several years, at least, France enjoyed under his rule a wise and mild administration, which secured for the young king a popular affection which even subsequent misfortunes failed to obliterate. In 1392 Charles, while marching against the duke of Brittany, was violently frightened by the sudden appearance of a ragged maniac, who stopped his horse and cried: "Do not proceed further, noble king; you are betrayed." This overpowered his already weak mind, and he fell into a state of derangement, which was the next year aggravated by his running the risk of being burned alive at a masquerade ball. Henceforth he was disabled from attending to the duties of his position; and his uncles again seized the reins of government, the duke of Burgundy managing to secure his own ascendancy. The king's brother, Duke Louis of Orleans, soon attempted to snatch the power from his hands, and two opposite parties, Orleanists and Burgundians, arose to divide the court and the nation. The contest grew fiercer when John the Fearless of Burgundy succeeded his father, Philip the Bold, and his hatred toward his cousin of Orleans could only be gratified by causing the latter to be murdered, Nov. 23, 1407. The count of Armagnac, the leader of a formidable soldiery from the south of France, at once espoused the cause of Orleans, and henceforth this faction was called by the name of Armagnacs. Civil war commenced between these and the Burgundians, and the unfortunate king was entirely neglected and left to the care of menials; while his wife, Isabella of Bavaria, whom he had married in July, 1385, gave herself up to amours and political intrigues. The daughter of a horse dealer, Odette de Champdivers, sometimes styled the little queen from having been his mistress, was almost the only one who brought any consolation to the king's distracted mind. During his lucid intervals he had sense enough to sympathize with the misfortunes of France. The condition of the country was becoming worse every day, when a new enemy appeared in the person of Henry V. of England, who, landing on the coast of Normandy, gained a victory over the French at Agincourt, Oct. 25, 1415, as complete as those of Crécy and Poitiers. France was everywhere given up to pillage, murder, fighting, and bloodshed. At the end of four years there seemed to be a lull, and negotiations were entered into;

but the treacherous murder of John the Fearless, perpetrated in the presence of the dauphin Charles, Sept. 10, 1419, gave a new impetus to the civil war. Philip the Good, son of John the Fearless, eager to avenge his father's death, concluded a treaty at Troyes May 21, 1420, with the treacherous wife of Charles and Henry V. of England, in virtue of which the latter received the hand of the king's daughter Catharine, with the regency of France for the present and the assurance of succeeding to the throne after the king's death. In all these transactions the unfortunate prince had of course nothing to do, except to sanction them by his presence or signature. Henry V. did not long enjoy his prospect of grandeur, dying Aug. 31, 1422. Charles himself died shortly afterward, leaving most of France in English hands.

CHARLES VII., the Victorious, the fifth king of the house of Valois, born in Paris, Feb. 22, 1403, died at the castle of Mehun-sur-Yèvre, near Bourges, July 22, 1461. The fifth son of Charles VI. and Isabella, he became by the early death of his brothers heir apparent to the crown in 1416. In 1417 he was appointed lieutenant of the kingdom, and shortly afterward he assumed the title of regent, without however being able, on account of his indolent habits, to exert any authority; he was but a tool in the hands of his favorites, most of them leaders of the Armagnac faction. On the death of Henry V. and Charles VI. in 1422, Henry VI. of England was proclaimed king of France at St. Denis, and his authority recognized by the majority of the people, while Charles was supported only by a few citizens of central and southern France. He was so poor and powerless that his enemies called him the *roi de Bourges*, as if this city were the whole of his monarchy. The duke of Bedford, who governed in the name of Henry VI., successfully waged war against Charles, and the English troops, victorious in several encounters, concentrated themselves around Orleans, which was the stronghold of the French king. His position was utterly helpless, when suddenly a young peasant girl, Joan of Arc, the celebrated "maid of Orleans," came to his rescue. Her enthusiasm, patriotic devotion, and confidence in victory inspired the French troops with new ardor, while terror spread among the English. Orleans was delivered, the enemy repeatedly defeated, and the king triumphantly brought to Rheims, where he received the holy unction. From this time Charles was indeed the real king in the eyes of the whole people, who everywhere rose in his behalf. The war became a national one, in which the lower classes, who had until then remained nearly indifferent, took an active part. The capture and death of Joan of Arc, far from damping the popular enthusiasm, kindled a new spirit. The French gained considerable advantages; and finally the treaty of Arras, concluded in 1435, between the king and Philip of Burgundy, insured their ultimate triumph. Henceforth Charles appeared to be

a new man; he distinguished himself by wisdom, prudence, and bravery; he achieved the task which had been commenced by others, and partly deserved the glorious appellation which has been attached to his name. Peace was reestablished, order and tranquillity prevailed, and prosperity revived throughout the kingdom. A regular army was organized from 1439 to 1448; the finance department, the administration of justice, and the other branches of the government were put on a better footing. In many of his reforms Charles was assisted by Jacques Cœur, the richest and most enterprising merchant of the time, whom he had made minister of finance. The improved condition of the country secured the sympathies and, on the renewal of hostilities, the assistance even of those provinces which were still held by the English. Consequently, in the space of a few months, the foreigners were expelled from Normandy and Guienne; and in 1453 the whole of France had returned to its native king, except Calais, which alone remained for another century in the hands of the English. In this great work Charles VII. had been powerfully assisted by the popular feeling, the prominent representatives of which were Joan of Arc, the heroine, and Jacques Cœur, the merchant; to both he proved ungrateful, leaving the former at the mercy of the English, without the slightest attempt at her liberation, and proscribing the latter, to whose financial assistance he was especially indebted. The celebrated pragmatic sanction, which secured the freedom and privileges of the Gallican church against the encroachments of the Roman see, was negotiated by him in 1438. His later years were embittered by the intrigues and rebellions of the dauphin, the future Louis XI.; his fear of being poisoned by his son became so overwhelming, that he finally refused to take any food, and died of starvation.

CHARLES VIII., the seventh king of the house of Valois, born at Amboise, June 30, 1470, died April 7, 1498. Being only 13 years of age on the death of his father, Louis XI., his eldest sister, Anne de Beaujeu, seized the reins of government, overpowered Louis of Orleans and his associates, who attempted to resist her, and ruled France in peace and prosperity till her brother became of age. The chivalric romances and accounts of Charlemagne's heroic deeds had imbued his weak mind with the idea that it was his mission to restore the Roman empire, and to take Constantinople from the Turks. At the head of a powerful army he entered Italy in 1494, triumphantly marched through the peninsula, and took possession of Naples. Satisfied with his military exploits, he left a part of his army in Naples, and hurried home with a select body of about 9,000 soldiers. When in the neighborhood of Parma, he encountered at Fornovo an army of 40,000 Italians, whom he routed (July 6, 1495), and triumphantly reentered France. He soon learned that his army had been defeated by

the Spaniards under Gonzalvo de Cordova, and that the kingdom of Naples had returned to its old allegiance (1496). He was planning a new expedition when he suddenly expired from the effects of an apparently trifling accident.

CHARLES IX., the twelfth king of the family of Valois, born at St. Germain-en-Laye, June 27, 1550, died May 30, 1574. The second son of Henry II. and Catharine de' Medici, he succeeded his brother, Francis II., Dec. 5, 1560, when only 10 years old, under the regency of his mother. The hatred between the Catholics and the Protestants had been growing for years past; an attempt at conciliation through the conference of Poissy having proved a failure, hostilities soon broke out. The Protestants resorted to arms, headed by the prince of Condé. After being successful in the first encounters, they were defeated at Dreux in 1562 by the duke of Guise, who was assassinated a few months later while besieging Orleans. A treaty of peace, known as the edict of Amboise, was concluded March 19, 1563, between the regent and the leaders of the insurgents. The war was renewed in 1567, when the Protestants were again defeated at St. Denis by Montmorency. A new peace intervened, which was of very short duration, the enemies being again in the field toward the middle of 1568. This third war was signalized by the battles of Jarnac (March 13, 1569) and Moncontour (Oct. 3), won by Henry, duke of Anjou, the younger brother of the king; then peace, now believed to be final, returned again. The king himself, Queen Catharine de' Medici, and the whole court, seemed to be reconciled to the Protestant party; Coligni was received with great honor by his young sovereign, who fondly called him "father," and required his advice in the administration of the government; the king of Navarre, afterward Henry IV., married the king's sister, Margaret; the other Protestant chiefs were welcomed at the court. Charles IX., above all, tried to foster concord and friendship between the recent enemies, so that those uninitiated in the secret councils of the court were assured that all were safe, when suddenly it was reported that Admiral Coligni had been shot by a man commonly known as the king's assassin. This was an awful warning, but it was too late for the Protestants to take measures for their security; they were unarmed and defenceless. About daybreak on Aug. 24, St. Bartholomew's day, 1572, at a signal given from the Louvre, the Catholics of Paris rose in arms and mercilessly slaughtered their opponents, who had confided in the word of the king. It is difficult to determine what was the part of Charles IX. in the fatal deed. He seems to have acted under the pernicious influence of Catharine de' Medici. This terrible woman drew from him the frantic exclamation, which was construed as an order: "Well, then, kill them all, that not a single Huguenot may live to reproach me with their death!" He frequently afterward manifested signs of deep

remorse, and breathed his last when only 24 years of age, amid dreadful corporal and spiritual sufferings.

CHARLES X., the seventh and last king of the family of Bourbon, born at Versailles, Oct. 9, 1757, died at Görz, in Austria, Nov. 6, 1836. He was the fourth son of the dauphin, son of Louis XV., and received at his birth the names of Charles Philip, and the title of count of Artois. After being very indifferently educated under the superintendence of the duke de la Vauguyon, he married, Nov. 16, 1773, Maria Theresa of Savoy, a younger sister of the countess of Provence, by whom he had two sons, the dukes of Angoulême and Berry. Being of a very profligate disposition, he neglected his wife, both for ladies at the court and common courtesans. Among the latter was Mlle. Duthé, who enjoyed an unenviable celebrity. His scandalous conduct was, however, somewhat restricted by the influence of the dauphiness Marie Antoinette, and his love for Mme. de Polastron. On one occasion he rashly insulted his cousin, the duchess of Bourbon, at the opera ball; and his duel with the duke which grew out of this circumstance seriously impaired the favor which his affable and courteous manners had gained for him. He tried to make amends by distinguishing himself at the siege of Gibraltar, but in vain; his levity and inconsistency had destroyed the last vestige of his popularity. When the revolution broke out he became one of its most uncompromising enemies. But instead of supporting his unhappy brother, Louis XVI., he fled from Paris to Brussels, then to Turin, where he engaged in intrigues, the consequence of which was to increase the danger to which his brother was exposed. On May 20, 1791, he had an interview with the emperor Leopold at Mantua, and a few months later was present at the conference of Pilnitz, the only result of which was to give a new impetus to the revolutionary spirit in France. While he was going about begging assistance for the royalist cause, the king was arraigned before the convention, sentenced to death, and executed. The exiled prince, who now assumed the title of Monsieur, repaired to Russia, where Catharine II. presented him with a magnificently ornamented sword bearing this inscription: "*Donnée par Dieu pour le Roi.*" But this was a useless weapon in such weak hands. The ill-directed efforts of the Bourbons and their allies having proved fruitless on the Rhine, it was thought proper to give encouragement and assistance to the Vendéans or Chouans. Monsieur was consequently sent, in August, 1795, with English ships, to effect a landing on the coast of Brittany. Although supported by a large number of emigrants and some 2,500 English troops, the brave Charette, who was in waiting for him, having gathered nearly 20,000 Vendéans, and engaged his word that 60,000 more would rise in arms on the arrival of a Bourbon, the prince did not dare to land, and his cowardice was the signal of the ultimate defeat of

the monarchical party in western France. He afterward lived in obscurity, residing mainly in England, till the fall of Napoleon, when he repaired to Paris, and on April 12, 1814, was welcomed there by the provisional government, headed by Talleyrand. A part of the Parisian population hailed his return, while his affability of manners and kind words conciliated the good will of many. The most popular saying reported of him at the time was: "Friends, nothing is changed in France; there is only one Frenchman more." Notwithstanding this favorable beginning, 11 months had hardly elapsed when Monsieur was again compelled to leave France, after having vainly tried to secure the city of Lyons against the approach of Napoleon. The defeat of the emperor at Waterloo brought him back again to France in the train of the allied armies. During the first years of the restoration he kept aloof from public affairs; but he was the head of the ultra-royalist party, which so seriously interfered with the policy of Louis XVIII. That party at last prevailed, after the assassination of the duke de Berry (1820), by the accession of the Villèle cabinet, and the influence of Monsieur became prominent. He succeeded Louis XVIII., Sept. 16, 1824, under very favorable auspices, his brother not having been a favorite with the nation. At first he adopted some popular measures; but soon his government appeared to be ruled solely with a view to the reëstablishment of the old régime. A bill to indemnify the emigrants for their losses during the revolution was introduced; this bill, by which the nation was to assume a thousand millions of new debts, in behalf of those who had actually borne arms against it, was adopted in March, 1825. This was a great triumph for the reactionary party. Soon another bill was passed, decreeing the most severe penalty against what was called sacrilege. In the legislative session of 1826 an attempt was made to alter the law of inheritance, so as to reëstablish the right of primogeniture; this, however, failed. Another bill, to regulate or rather to destroy the freedom of the press, called *loi de justice et d'amour*, was not more successful. The public discontent was further increased by the favor shown by the government to the Jesuits, who had reëstablished themselves in France under the new appellation of *pères de la foi*. At last the popular sentiment broke out during a review of the national guards, held April 29, 1827, by the king himself; he was received by the cries of "Down with the ministers," "Down with Villèle." Greatly provoked by these manifestations, his haughty answer was that he "came to receive homage, not lessons." On the same night a decree of dissolution was issued against the national guards. A few weeks later the chamber of deputies was also dissolved, while the royalist party was reënforced in the chamber of peers by the addition of 76 new members. At the same time the freedom of the press was entire-

ly suppressed by the reestablishment of the censorship. To divert public attention, the government resolved on assisting Greece in her war of independence, but the glory achieved by French arms failed to restore popularity to the cabinet; and Charles X. at last consented to part with his ministers and choose new counsellors among the most liberal royalists. The Martignac ministry, formed Jan. 4, 1828, was the signal of a kind of reconciliation between the king and the nation. The measures then adopted were hailed with delight by the friends of constitutional liberty, but created the utmost dissatisfaction among the court party. The king, fearing the ascendancy of liberal principles and following the suggestions of the ultra royalists, dismissed the Martignac administration, and intrusted Prince Polignac with the formation of a new cabinet. The prince was the truest representative of that old royalist party which had "forgotten nothing and learned nothing." His mere name was considered as a challenge offered by the king to the nation; every one foresaw the coming struggle. In vain the government tried to assuage public opinion by the excitement of military success. The expedition against Algiers was undertaken; that stronghold of piracy was stormed on July 5, 1830. But all to no purpose; the interest of the whole nation was engrossed by home affairs. On the opening of the chambers, March 2, the king had made use of threatening language, and to this a majority of 221 deputies answered by voting an address declaring their want of confidence in the ministry. The king declined to receive the address, on which the chambers were adjourned, and on May 16 they were dissolved. New elections took place, and resulted in a still more powerful opposition majority. Incensed at this, and encouraged by the triumph of the French army in Algeria, the king resorted to a *coup d'état*. Decrees were promulgated suppressing entirely the freedom of the press, dissolving the newly elected but not yet opened chamber of deputies, and prescribing an essential modification in the mode of election, so as to secure the triumph of the court party. These ordinances fell like a thunderbolt on Paris. Resistance was immediately organized; barricades were built, and defended by bodies of workmen from the suburbs, and by artisans and printers, under the command of officers and young men from the polytechnic school. The insurrection was emphatically popular, and not confined to any particular class. The royal troops, under Marshal Marmont, offered slight resistance, and were driven from the capital in less than three days (July 27-29). Charles X. was so little conscious of the danger of his situation that he remained quietly at the palace of St. Cloud; he learned but gradually the defeat of his troops, being to the last under the impression that he had to deal only with a riot. But it was a revolution, and when he attempted to avoid its consequences it was too late. He recalled the fatal ordi-

nances, appointed a liberal ministry, and even abdicated in favor of his grandson, the duke of Bordeaux, the present count of Chambord, his surviving son, the duke d'Angoulême, equally resigning his rights. But the chiefs of the revolution would not accept such proposals; the king had no alternative but to depart. He retired first to Trianon, then to Rambouillet, under the protection of his guards. In the latter place he made some show of resistance; but on the appearance of 10,000 volunteers from Paris, he gave up entirely, and, accompanied by commissioners sent by the chamber of deputies, he directed his course toward Cherbourg. There, on Aug. 16, he embarked for England with his family and a few faithful servants, on board of two American ships, the *Great Britain* and the *Charles Carroll*. He landed at Cowes under the name of count de Ponthieu, and immediately repaired to the palace of Holyrood, in Scotland, which had been assigned to him as a residence by the English government. In this retreat he devoted his time to field sports, of which he was still very fond notwithstanding his old age, and to religious duties. After four years' residence, he left Scotland for Bohemia, where he lived successively at Buschtierad and the Hradschin in Prague. Finally he resolved to retire to Görz, and arrived there in October, 1836, but soon died of the cholera, after a sickness of five days.

III. GERMANY.

CHARLES I., Charlemagne, or Charles the Great (Ger. *Karl der Grosse*), emperor of the West and king of France, born according to some in Aix-la-Chapelle, according to others in the castle of Salzburg, near Neustadt, in the Bavarian district of Lower Franconia, April 2, 742, died in Aix-la-Chapelle, Jan. 28, 814. The second son of Pepin, the Frankish king, whose dominion reverted to him and his brother Carloman on his father's demise in 768. Carloman dying three years later, Charles secured the undivided sovereignty. He now found himself master of the whole of Gaul and western Germany; his ambition, however, was unsatisfied, and a succession of fortunate wars in Italy, Spain, and Germany added largely to his already extensive dominion. His first conquest was that of Lombardy. Motives of discontent and estrangement had for several years existed between him and Desiderius, king of the Lombards. He had before his accession to the throne married Desiderata, the daughter of the latter, and had recently sent her back in a scornful manner to her father. Desiderius himself had granted an asylum to the nephews and some of the bitterest enemies of his son-in-law; at the same time he assumed a hostile attitude toward the popes of Rome, whom Pepin had made firm allies of the Carolingians by bestowing upon them the exarchate of Ravenna. Charlemagne, yielding to his own anger and to the entreaties of Pope

Adrian I., crossed the Alps in 773 at the head of a powerful army, besieged Pavia for eight months, and took possession of it only when its defenders had been disabled by pestilence and famine. Desiderius was exiled to the monastery of Corbie in France, and Charlemagne crowned himself with the ancient iron crown of the Lombard kings; but he had scarcely left Italy when Adelgis, son of Desiderius, supported by the dukes of Spoleto, Friuli, and Benevento, rose in arms against the conqueror. The rebels were crushed at once, and Charlemagne, to make the submission of Lombardy more sure, appointed his second son, Pepin, to reign over the country (776). Meanwhile war was actively prosecuted against the Saxons; the most important, protracted, and terrific of all his wars. Commencing in 772, it terminated only in 804, after a duration of 32 years, with very little interruption. On his first expedition, he took Eresburg, destroyed the venerated statue known as *Irmingsaul*, and penetrated victoriously as far as the Weser. But the Saxons were far from being conquered. In 775 he invaded their country again, slaughtered all who offered resistance, devastated the towns which were not prompt enough in their submission, and now considered his power firmly established. Far from it; they rose the following year, and, notwithstanding repeated defeats, renewed their resistance in 777, but were again subdued. Charlemagne's power now seemed securely established. He held a *placitum* at Paderborn, where many Saxon tribes acknowledged his authority and were baptized. Wittikind, their intrepid chief, the hero who inspired them with his courage and love of independence, had been obliged to take refuge with a northern prince. Charlemagne improved this interval of apparent tranquillity to make war on Abderrahman, the new caliph of Cordova. Crossing the Pyrenees in 778, he took Pamplona, Saragossa, and the territory as far as the Ebro; but a severe misfortune attended his return to France. The rear guard of his army was overtaken in the narrow passes of Roncesvalles by the Basques, the inveterate enemies of the Franks, and destroyed to the last man; among the valiant chiefs who were slain was Roland, whom history scarcely notices till his later renown in the annals of chivalry. But the presence of Charlemagne was required on the Elbe; the indomitable Saxons had revolted again under Wittikind; they could not endure the foreign yoke, and, above all, they hated Christianity. Charlemagne adopted against them measures of the greatest severity and cruelty; more than 4,000 prisoners were at one time slaughtered; many thousands of the Saxons were transplanted with their families into Frankish countries; part of Saxony was laid waste, and every means resorted to to crush the spirit of its inhabitants. Two great battles, which took place at Detmold in 783, destroyed their last forces, and Wittikind, despairing of the future, surrendered in 785,

swore allegiance to Charlemagne at Attigny-sur-Seine, and was baptized. This, however, was far from being the last of these bloody struggles; the independence of Saxony found other champions, who more obscurely, but not less heroically, undertook their patriotic task. The alternate succession of risings and defeats went on almost uninterruptedly, until Saxony, completely exhausted by repeated losses, and bent down under the despotic organization devised by the conqueror, had no recourse but to give up her national freedom and religion. The diffusion of the gospel was aided by conquest; the bishoprics or missionary stations of Minden, Halberstadt, Verden, Bremen, Münster, Hildesheim, Osnabrück, and Paderborn were the origin of as many cities; and the old Saxon nationality was completely broken down. While this desperate struggle was still at its height, Charlemagne had to baffle the treacherous designs of Tassilo, the Agilolfingian duke of Bavaria, who, although a tributary of the Frankish monarch, held secret intercourse with his enemies, and attempted to unite the Saxons, the Lombards, the Avars, the Slavs, and the Saracens against him. The duke was arrested, arraigned as a traitor before an assembly of lords at Ingelheim in 787, and sentence of death passed upon him, which, however, was commuted to imprisonment in the monastery of Jumièges, near Rouen. Bavaria was now divided into counties under Frankish governors. Charlemagne afterward conquered several of the Slavic tribes along the banks of the Baltic, undertook a war of extermination against the Avars, which lasted from 794 to 796, and put their country under the administration of Frankish counts and bishops. Having thus taken possession of the northeast of Spain, the larger part of Italy, and northern and eastern Germany, he found himself at the close of the 8th century master of an empire bounded N. by the Baltic sea, the Eider, the North sea, and the British channel; W. by the Atlantic ocean; S. by the Ebro, the Mediterranean, the Volturno, and the Adriatic; and E. by the Theiss and the Oder. Margraviates, or military marches, were established for the protection of the land frontiers, while fleets were in readiness on the seashore to oppose the piratical invasions of the Saracens and the Northmen. So extensive a dominion seemed fully to warrant a higher appellation than that of king; and moreover, the ultimate aim of his conquests had been the restoration of the western Roman empire. Having been induced to visit Italy to protect Pope Leo III. against his rebellious clergy, the Frankish king was solemnly and triumphantly crowned by the grateful pontiff in St. Peter's church, on the Christmas day of the 800th year of the Christian era. Henceforth he styled himself emperor of the West, and, with a view of reëstablishing the ancient Roman empire, proposed to marry Irene, the Byzantine empress; a project baffled by her deposition.

This was a great era in the middle ages. The Christian kings of Spain, the Mussulmans of Fez, and the caliph of Bagdad, Haroun al-Rashid, sent ambassadors to present homages and gifts to the powerful western monarch.—However great as a warrior and the founder of an empire, Charlemagne deserves still more praise as a lawgiver, a civilizer, and a patron of learning, science, and art. He endeavored to establish order and a regular administration among the many nations which his sword had united, most of which were in a barbarous condition, totally different in their origin, language, and manners, and hostile to each other. Great national assemblies, known as *champs de Mai*, were held yearly in the spring. (See CHAMP DE MARS.) Other assemblies took place in the autumn, but were merely councils of military and ecclesiastical lords whose advice the emperor was pleased to receive, and who under his directions prepared the bills and projects to be submitted to the national meeting. In addition to the laws thus adopted by the nation, Charlemagne issued edicts known as capitularies, in which regulations for the administration of the empire as well as the management of the emperor's private property were enacted. The collection of these capitularies, a number of which have been preserved, is among the most valuable relics of the middle ages, and affords striking evidence of foresight, wisdom, and prudence in their author. His empire forming ethnologically various kingdoms, Charlemagne placed at their head his own sons with the title of kings; but they were nothing more than his lieutenants, the supreme power being concentrated in his own hands, he alone appointing the officers intrusted with the administration. His whole dominion was divided into a number of counties governed by earls (*Grafen*), and these were placed under the supervision of imperial delegates, or *missi dominici*, who four times every year visited the circuits assigned to them, holding provincial meetings and courts of justice, receiving the accounts of the collectors of public money, and adjusting the grievances of the people. He was thus enabled to control every branch of administration, as well as the proceedings of the various functionaries, who were appointed for a term of three years only. His protection extended to the clergy, increasing their wealth by a law upon tithes, their liberty by his respect for canonical elections, and their power by certain judicial prerogatives; but at the same time keeping them under his dominion, submitting them to the *missi dominici*, restricting their rights of asylum, interfering with questions of discipline and even of dogma, and causing the monasteries to be reformed by Benedict of Aniane. Trade and industry were not less objects of his fostering care; he granted privileges to merchants, and reduced as much as possible the tolls to which they were subjected. He established uniformity of currency, had the coinage executed in his palace, and regu-

lated the value of gold and silver coin. Beggars were not permitted to prowl about the country, but were provided for by the lords or communities to which they belonged. He bestowed particular attention upon general instruction and the revival of classical learning. Illustrious men were invited to his court from all parts of the world, and especially from Italy, to diffuse among his subjects various branches of learning, as grammar, rhetoric, logic, arithmetic, astronomy, history, theology, and medicine. The Anglo-Saxon Alcuin, a man of considerable information, if not thorough learning, seems to have been the leading spirit of this aggregation of teachers; he was the originator of the palatine school, a kind of normal institution, from which men thoroughly instructed were sent into the provinces, and constituting at the same time an academical society, which consisted of the emperor himself, several members of his family, mostly females, and the most distinguished of his courtiers. The academicians assumed names borrowed from antiquity; Charlemagne himself was styled David, while two of his daughters, Gisela and Rothruda, were called Delia and Columba. These ladies and some others were also engaged in making copies of ancient manuscripts, which task, however, specially devolved upon the monks of various monasteries. The emperor gave encouragement to this calling, paying largely for such copies, and establishing a library in his own palace at Aix-la-Chapelle. He himself was eager in his desire of knowledge and science, conversing with the learned in his leisure hours, and having books read to him during his meals. In the night he would frequently get up to study the course of the stars. Through such diligent application he became as much of a scholar as was consistent with his public duties; and some literary works were due to his encouragement, such as a German grammar and a collection of the national songs of ancient Germany. The fine arts were far from being neglected by him; he had the Gregorian chant adopted in the churches, and brought singers from Italy, whose concerts he patronized. Among the many palaces constructed by his order, we must mention those of Ingelheim, Nimeguen, and Aix-la-Chapelle. The last was a masterpiece of architecture, having been ornamented with columns and sculptural fragments brought from Italy; it was a large and magnificent building, the spacious halls and rooms of which were decorated in a splendid manner, and filled with most elegant and costly furniture. The basilica in the same city, erected also by Charlemagne, was equally celebrated, and became the pattern of many churches built during the 9th century. He moreover encouraged civil engineering; a wooden bridge 500 paces long was constructed at Mentz over the Rhine; and a gigantic canal was commenced, but not completed, to establish through this river and the Danube a water communication between the North and Black seas.—Char-

lemagne was of a tall and commanding figure; either standing or sitting, he had an air of grandeur and dignity; and notwithstanding the shortness of his neck and his obesity, he was well proportioned and remarkably active, with a firm step and manly appearance, his shrill voice alone being not in accordance with his person. An adept in the use of weapons, he was also an unrivalled swimmer and a consummate hunter. Although encouraging magnificence of attire among his courtiers, he was generally plainly dressed, giving preference to the old Frankish style of costume. He was frugal and temperate, and evinced great severity against drunkards. He had nine more or less legitimate wives, by whom he had at least twenty children. The only son who survived him was his successor, Louis le Débonnaire. Several of his daughters led a dissolute life and caused great scandal. The awe with which Charlemagne inspired his contemporaries increased as time rolled on; his historical deeds, amplified and adorned by poetry, powerfully seized upon the popular imagination; and the great emperor and his twelve legendary peers became the heroes of innumerable chivalric romances, which were recited or sung everywhere, and the collection of which is now styled "The Carolingian Cycle." His name has also won a halo of sanctity, the anti-pope Pascal III. having canonized him in 1165, and Louis XI. having ordered his anniversary to be celebrated on Jan. 28. The origin of many pious or learned institutions has been ascribed to him; and fiction and truth are so much blended in his history that it is difficult to disentangle the one from the other. But, however this may be, Charlemagne takes rank among those extraordinary men who, from time to time, appear to change the face of the world and inaugurate a new era in the destinies of mankind.—The cathedral of Aix-la-Chapelle stands on the site where Charlemagne had erected a chapel, which he designed as his burial place. The chapel was destroyed by the Normans, and rebuilt in its present form by Otho III. toward the close of the 10th century. The position of the tomb in which once reposed the remains of Charlemagne is marked by a slab of marble under the centre of the dome, inscribed with the words *Carolo Magno*. When the vault was opened by Otho III., the body of Charlemagne was found seated on his throne, clothed in the imperial robes. These relics are now deposited in Vienna, excepting the throne, which alone remains in the cathedral of Aix-la-Chapelle.—The literary works attributed to Charlemagne are: 1, his "Capitularies" (first collected by Ansegise, abbot of St. Wandrille; best edition that of Étienne Baluze, 2 vols. folio, Paris, 1677); 2, "Letters" contained in the collection of De Bouquet; 3, a "Grammar," of which fragments are to be found in the *Polygraphia* of Trithemius; 4, his "Testament," contained in Bouchel's *Bibliothèque du droit français*, tom.

iii. (folio, Paris, 1677); 5, some Latin poems, such as the "Epitaph of Pope Adrian" and the "Song of Roland;" 6, the "Caroline Books."—Among the books which treat of Charlemagne, we may refer to the great biography of his contemporary, Eginhard, *Vita Caroli Magni*, in Duchesne's *Rerum Francorum Scriptores* (best edition by Pertz, in the *Monumenta Germaniæ Historica*; Monachus Sagalensis, *De Gestis Caroli Magni Libri II.*; Donatus Acciaiolus, *De Vita Caroli Magni Commentarii*; Leclerc de la Bruère, *Histoire du règne de Charlemagne*; Hauréau, *Charlemagne et sa cour*; Struve, *Rerum Germanicarum Scriptores*, tom. i.; Dippold, *Leben Kaiser Karls des Grossen* (Tübingen, 1810); Gaillard, *Histoire de Charlemagne* (2d ed., 4 vols., Paris, 1819); Lorenz, *Karls des Grossen Privat- und Hofleben*, in Raumer's *Historisches Taschenbuch* (1832); Abel, *Jahrbücher des fränkischen Reichs unter Karl dem Grossen* (Berlin, 1866 *et seq.*). Piper has edited from the original MS. *Karl des Grossen Kalendarium und Ostertafel* (Berlin, 1858). Among the more popular works upon this monarch may be mentioned the "History of Charlemagne," by G. P. R. James (1832), and Bulfinch's "Legends of Charlemagne" (1863).

CHARLES II. See CHARLES II., THE BALD, France.

CHARLES III., the Fat, the last emperor of the Carolingian dynasty, born about 832, died in 888. He was the third son of Louis the Germanic, and received the kingdom of Swabia for his portion of his father's possessions. After the death of his oldest brother, Carloman of Bavaria, in 880, he succeeded him in the imperial dignity and in the possession of Italy; and after that of his younger brother, Louis of Saxony, in 882, he became king of all Germany. On the death of Carloman of France in 884, Charles the Fat united France under his sceptre with Germany and Italy, and the vast empire of Charlemagne was thus again vested in one and the same sovereign. He proved, however, unworthy of this exalted position. He became a passive tool in the hand of his minister, an inactive spectator of the sufferings of his people, and was covered with domestic as well as public disgrace. His incapacity and cowardice soon became manifest. Paris being besieged by the Northmen, he marched against them with a large army from Germany; but instead of fighting the enemy, he offered them large sums of money and the pillage of Burgundy to obtain their retreat. This shameful conduct raised general indignation; the Bavarians, Saxons, Thuringians, and finally the Alemanni, deserted him and deposed him solemnly in an assembly at Trebur in 887. He had already been disowned by the French. He died the next year, poor and forsaken, in a cloister near Constance. He was noted for inordinate love of the pleasures of the table, and this as well as his corpulence gave him the surname of "the Fat."

CHARLES IV., emperor of Germany, a member of the family of Luxemburg, and son of King John of Bohemia, born in Prague, May 13, 1316, died there, Nov. 29, 1378. When seven years old he was taken to Paris to be educated at the French court; but on the death of the French king Charles IV. in 1328, his father removed him to the court of Luxemburg, and after a four years' residence there summoned him to Italy, where King John had been appointed the viceroy of the emperor Louis the Bavarian, with whom he was at that time in close friendship. The viceroyalty was now for a time transferred to Charles, who soon exchanged the onerous office for the margraviate of Moravia. The relations of King John with the emperor had in the mean time changed, and they soon became openly hostile. In the war excited by Louis's summary disposition of Carinthia, John joined the opponents of the emperor; and Charles, acting as his father's ally, conquered and laid waste (1337) the lands of the count von Görz, one of the most important of his enemies. In the few years following the Carinthian war the enmity which had long existed between Louis and the popes grew more and more bitter. Clement VI., who succeeded to the papal chair in 1342, in the next year renewed the excommunication already pronounced against the emperor, pushed his hostility so far as to excite for a time the resistance of the German diet, and spared no pains to raise up enemies to Louis throughout the empire. Among these enemies Charles already occupied a leading place when, in 1346, his father's death at the battle of Crécy left him king of Bohemia. The time now seemed to have arrived for a successful and final opposition to Louis's rule; and at the instigation of the pope five electors and a great number of the papal party met at Rhens on the Rhine and chose Charles emperor, in July, 1346, but not until he had submitted to such humiliating conditions as they wished to impose upon him. In spite of this election he was still too weak to actually assume the imperial dignity in anything but name, and Louis maintained his position successfully until his death in 1347, an event which seemed at last to leave Charles's way entirely clear. But no sooner was his chief rival dead than new opponents met him. The electors of the Palatinate and Brandenburg, with other powerful rulers, declared his election void, and offered the imperial crown first to Edward of England, who refused it; then to the margrave of Meissen, who also declined it; and finally to Count Günther of Schwarzburg, who accepted it. Charles made no preparations for an open conflict with this formidable antagonist, but devoted himself to aiding various schemes against Günther's supporters—upholding the pretensions of Waldemar, a pretender to the electorate of Brandenburg, and endeavoring by this and similar means to compel his enemies to withdraw their aid from his rival. The con-

test was soon terminated, however, by the withdrawal of Günther himself, and his death soon afterward, brought about, it was said, by poison; a report which Charles's enemies everywhere used against him. Charles now sought a reconciliation with his opponents; he took for his second wife the daughter of the elector palatine, and gave his own daughter in marriage to Duke Rudolph of Austria; and finally so won over those who had opposed his election that they gave in their adhesion, and he found himself at last in undisputed possession of the imperial throne. The next few years he employed in plans for increasing the power and wealth of his immediate family. He secured through his father-in-law the right of inheritance to the Palatinate; and on the death of his second wife he married the daughter of Duke Henry of Jauer, gaining with her the prospective possession of the principality. In 1354 he visited Italy, and was crowned king of that country, his coronation being celebrated with great pomp at Milan. In the spring of 1355 he was crowned emperor at Rome by Cardinal Bertrandi, but, according to a vow imposed upon him, he spent but one day within the city walls. His conduct with regard to the great political disputes then agitating Italy was indecisive and spiritless; he made enemies both of the Guelphs and the Ghibellines, and seemed to care for little but the acquisition of large sums of money, which he took with great avidity in return for the various honors and privileges he bestowed. Hated by all parties, he hastened back to Germany soon after his coronation. In 1356 he issued the famous "golden bull," prescribing the rights and duties of the electors and various princes of the empire, and the manner of the election of emperors; regulating taxes, the disposition of revenues, and the coinage; limiting the rights and privileges of cities; and containing other regulations for the administration of the affairs of the imperial government. This decree, which a German writer calls the only thing of importance that Charles did for the empire, remained for centuries one of the principal parts of its law; but the pope, enraged at finding himself left by its provisions almost powerless to influence elections, extorted as compensations from the emperor, who showed a life-long subservience to papal authority, numerous concessions of privileges to the clergy. Charles's weak rule permitted feuds and dissensions in every quarter of the countries he governed. Zürich and the duke of Austria carried on a war which Charles was compelled to end by forcible interference in 1356; later he himself became involved in difficulties with Swabia, and then with Count Eberhard of Würtemberg; while brotherhoods of knights little better than robbers, and princes in the prosecution of personal feuds, devastated and plundered at will throughout Germany. Troubles arose in Italy. The Visconti, whom Charles had confirmed in all their usurped power, ex-

exercised the greatest tyranny throughout the country, especially against the church; and in 1368 the emperor, summoned to the pope's aid, marched into Italy with a considerable army, only to allow himself to be bribed by the usurpers, and to retire with immense sums of money. During the remaining ten years of his life he occupied himself chiefly, as he had done throughout his reign, with care for the interests of his family and of Bohemia. By treaties, purchases, and all the means in his power, he added lands to the possession of his house; he had secured the right of inheritance to Brandenburg in 1363; in 1368 he had paid an immense sum for the possession of Silesia and Lower Lusatia; and in 1373 he annexed the margraviate of Brandenburg to Bohemia. By lavish gifts to the electors he secured the recognition of his son Wenceslas as his successor, and before his death devised to him also the crowns of Bohemia and Silesia. Such talents as Charles possessed were generally employed for purposes of deceit; he was neither a warrior nor a statesman, but devoted himself to schemes for money-getting with something of the petty spirit of a miserly trader—bargaining, overreaching, and employing the lowest means for gaining comparatively trifling sums. Such benefits as he conferred upon the empire were generally the indirect consequences rather than the direct objects of his plans; and although he paid some attention to education, art, the embellishment of the great cities, and the advancement of trade, yet he neglected the interests of the empire as a whole, and left it a prey to feuds and lawlessness.

CHARLES V., emperor of Germany, and king of Spain under the title of Charles I., born at Ghent, Feb. 24, 1500, died at the monastery of Yuste, near Plasencia, Spain, Sept. 21, 1558. He was the eldest son of Philip of Burgundy, archduke of Austria, and Joanna, daughter of Ferdinand and Isabella of Spain. His paternal grandfather was the emperor Maximilian, Philip of Burgundy being the offspring of that emperor's marriage with the beautiful Mary, daughter of Charles the Bold and Isabella of Bourbon. By the death of his father in 1506 Charles became, when only six years old, heir presumptive to the entire possessions of the house of Hapsburg in Germany, in right of his grandfather Maximilian, and to the dukedom of Burgundy, as it was then called, afterward the Spanish Netherlands, in right of his grandmother Mary. He was educated in this portion of his great possessions, under the care of William Croy, lord of Chièvres, who had him thoroughly instructed in the learning and accomplishments of the time; he brought him up stern, cold, regular in his life, and somewhat formal in manner; the tendency of his education being to make him rather a German in spirit than a Spaniard. By the death of Ferdinand, his maternal grandfather, in 1516, he inherited the whole kingdom of Spain, the

Castilian portions of which Ferdinand had governed since 1507 as regent, the kingdom of Naples, and the then literally boundless Spanish empire in America. In spite of his youth, he at once ascended the Spanish throne and took the conduct of affairs into his own hands. He was now the most powerful ruler in Europe. His boast that the sun never set on his dominions was justified by the greatness of his possessions. He bore on his escutcheon two globes, and had stamped upon his coin two pillars representing the pillars of Hercules (denoting the western limit of Europe), with the motto *Plus ultra* ("More beyond"). The armies at his command in his various territories were enormous; and the revenues upon which he could draw seemed practically unlimited. Thus situated, it was natural that Charles should direct his first aspirations toward the imperial power so long held by his grandfather. He was early looked upon as one of the leading candidates for the succession; and on the election following Maximilian's death in 1519 he was chosen emperor (June 28), Francis I. of France being his only really dangerous competitor for the honor. He was crowned at Aix-la-Chapelle Oct. 23, 1520, after having signed an agreement (the *Wahlkapitulation*) intended by the electors to restrain him in some degree in the arbitrary exercise of the immense power at his command. He entered upon his administration just as Luther had aroused Europe by those acts which formed the beginning of the reformation. The strong excitement now pervading Germany, and the multitude of unsettled questions besides this of the religious controversy, determined Charles to call a great diet for the discussion of affairs. It met at Worms in the winter of 1521; Luther appeared before it and made his memorable defence on April 17 and 18. But the emperor did not yet perceive the importance of the religious agitation which had arisen throughout the northern portion of his empire. His mind was still occupied with affairs in Spain, which were in a most unsettled state. He was also about to begin a war with France; for although he and his jealous and disappointed competitor Francis had sworn that the result of the election should not disturb the peace between them, a pretext was not long wanting to give the two rivals an opportunity to try their strength. Charles's delay in fulfilling his promise to restore Navarre to Henri d'Albret formed the wished-for excuse; it was made a *casus belli*, and both monarchs prepared for the conflict. With his attention principally occupied by these plans, the emperor was more annoyed by than interested in the religious controversies of Germany; he issued a decree of outlawry against Luther, hoping thus hurriedly to dispose of the matter in its beginning, and before the close of the year he left Germany for Spain by way of the Netherlands and England. His visit to the latter country was made for the purpose of gaining over Henry

VIII., whom Francis was endeavoring to persuade into an alliance in the coming war; and so far as defeating this plan was concerned, Charles's interviews with Henry were successful. Arrived in Spain, he subdued a revolt of the cities of Castile against the crown; but he had barely succeeded in restoring order when the French war broke out both along the borders of Navarre and of the Netherlands; and at the same time the Turks under Solymán captured Belgrade and penetrated into Hungary, the ill-fated king of which, Louis II., was Charles's brother-in-law. The French war first received Charles's full attention. The conflict rapidly extended, and attained its greatest force in Italy. The French at first met with success on the Spanish border, but they were defeated in the Netherlands; and Charles added greatly to his strength by at last gaining Henry VIII. of England to his side, after an unsuccessful attempt made at Calais to conclude a general peace. He now added to his previous good fortune a series of brilliant victories in Italy, won by his generals Prospero Colonna and Frundsberg. Another great gain for him was the desertion of the constable of France, Charles of Bourbon, to the imperial army. On Feb. 24, 1525, the battle of Pavia crowned his triumphs. Francis was taken prisoner, and was treated with courtesy by his conqueror, who, however, imposed such hard conditions of peace that the French king at first declared that he would rather remain a prisoner for life than submit to them. A compromise was at last effected, and though its conditions were but little better than those of the former offer, it was confirmed by the treaty of Madrid, Jan. 14, 1526; an agreement which left Charles even much more powerful than at the beginning of his reign. Meanwhile matters in Germany had been left largely under the charge of Charles's brother Ferdinand, to whom he had ceded his properly Austrian possessions, and who had conducted affairs in the empire with great skill and success. Through the conflict between the Swabian confederation and Duke Ulrich of Würtemberg, he succeeded in acquiring the latter's territory, which was subsequently given to Ferdinand, who, after the death of Louis II. at Mohács (1526), had become his successor both in Hungary and Bohemia. The confederation itself Charles made use of as a means of help against the Turkish invasion, which, after Mohács, threatened the empire itself. The result of the rapid increase of Charles's power was to excite the greatest anxiety among the governments of Europe, no one of which was now able to cope successfully with the emperor. Coalitions of several states could alone give any hope of adequate resistance to his encroachments. The pope, Clement VII., who perhaps had most of all reason to fear the growth of the imperial power, now formed an alliance with several Italian states and France; declared Francis absolved from his agreements in the treaty of Madrid, on the ground that the concessions he

had made had been extorted by force; and laid his plans for freeing all Italy from the rule of the emperor. But the coalition proved unavailing. The imperial troops under the constable de Bourbon penetrated to Rome, captured and sacked the city, and compelled the pope to surrender himself to Charles, treating the pontiff with no little indignity (May, 1527). The emperor now attempted to play a double part. He affected great indignation at the disrespect shown to the papal authority, declared that the capture of the pope's person had been made without his knowledge, and even assumed mourning, with his whole court, on account of his grief at the misfortunes of the holy father; but he continued to hold the pope a close prisoner for seven months. But Charles himself was now almost as desirous of peace as the members of the defeated coalition. He was in a position to force his enemies to accept the hardest terms, and on June 29, 1529, he signed with the pope the treaty of Barcelona; shortly afterward he also ended the war with Francis by the treaty of Cambrai (Aug. 5). By these treaties he gained possession of most of Italy, and compelled the payment of a large indemnity by his antagonists; the pope was forced to crown him at Bologna, and his power was more firmly established than ever. Charles now (1530) turned his attention entirely to the affairs of Germany. His first aim was to smooth over and pacify rather than to crush the religious dissensions now most violently agitating the country; for he needed the help of the German princes against the Turks, who had in 1529 even penetrated to Vienna. To further these plans, the emperor called a diet at Augsburg, which assembled in March, 1530. But all efforts at a reconciliation of the contending parties were useless. The opportunity given by the diet called forth in June the celebrated Augsburg confession, which only served to show more clearly than ever the impossibility of half-way measures; and when the emperor refused to recognize their creed as permissible in the empire, the Protestant princes in a body declared that they would give him no aid against the Turkish invasion; and, meeting at Smalcald in 1531, they formed a confederation which was secretly aided by England and France. The Turks continued their assaults; and by 1532 Charles found himself so hard pressed that he was forced at last to give way. By the Nuremberg agreement he engaged to permit the Protestants religious freedom for the time being, relegating the final question of the status of Protestantism to a council to be held in the future. Aided now by the Protestant forces, the imperial army advanced against the Turks, over whom Charles's general, Schärtlin, had in the mean time gained an important victory. The Mohammedans did not wait for actual conflict, but retreated through Hungary. The emperor now went to Italy, and debated with the pope concerning a projected council by which it was proposed to settle the affairs

of Germany; but he accomplished no immediate result. In 1535 he began from Spain a campaign against the Turkish pirates, who had possessed themselves of Tunis, and were annoying the Spanish fleets. Tunis was taken, and 22,000 Christian slaves who had been imprisoned there were restored to liberty. New troubles had broken out in Germany. Ulric of Württemberg had regained his possessions, and the Swabian confederation had been broken up (1533). A new war broke out with Francis I., who this time effected an alliance with the Turks; but though he invaded Italy at the same time that Solymán renewed his attack on Hungary, Charles's generals defeated both. A truce of ten years, agreed upon in 1538, with much talk of an enduring peace, had hardly begun before it was broken by a new disagreement about the terms upon which such a peace could be arranged. Henry VIII. of England now joined Charles; and after experiencing a severe defeat at Ceresole, and repairing it by victories in France and at sea, the latter again came out of the war as conqueror, at the peace of Crespy, Sept. 18, 1544. During the progress of the conflict he had also found time and means to make his power in Spain more nearly absolute through changes in the form of government (1539), to repress a revolt in the Netherlands (1540), and to undertake an expedition against Algiers (1541), which however was a failure. The peace of Crespy concluded, Charles again turned toward German affairs; and allying himself with the pope, Duke Maurice of Saxony, and his own brother Ferdinand, he began a campaign against the Protestant princes of the Smalcald league, who had aroused his anger by their opposition to the settlement of religious questions by a council. He defeated them in the battle of Mühlberg, April 24, 1547, took away the territory of the elector of Saxony and gave it to Duke Maurice, issued a decree against Magdeburg for espousing the Protestant cause, and finally, in a second diet at Augsburg (1548), issued the so-called *Interim*, a regulation fixing the degree of toleration and the forms of faith to be observed pending the still anticipated decision of the general council assembled at Trent. But his plans were suddenly defeated by a rapidly executed scheme of his former ally Duke Maurice, who was now alarmed at the apparent tendency of Charles's measures, and who allied himself with Henry II. of France, who had in 1547 succeeded Charles's old enemy Francis. In the summer of 1552 Maurice suddenly appeared with an army before Innspruck, where the emperor lay ill of the gout, at the same time that Henry invaded and took possession of a large portion of Lorraine. Charles fled before Maurice, narrowly escaping capture; he was unprepared for a war, and yielded to the Protestants' demands in the treaty of Passau, Aug. 2, 1552, which gave them entire religious freedom. He made some further efforts to

contend with Henry, but found himself unable to recapture what he had lost. Thus suddenly deprived of much of his power, depressed by illness, and disappointed in his chief plans, the emperor announced at the Augsburg diet of 1555 his intention of retiring altogether from the world. Resigning his kingdoms of Spain, the Indies, Naples, and the Netherlands to his son Philip in 1555-'6, he entered the Spanish monastery of Yuste, near Plasencia. His brother Ferdinand succeeded him as emperor. At Yuste Charles spent the remainder of his life, still endeavoring to exercise influence on the politics of Europe, remaining in constant correspondence with the principal men of the various states, and strangely mingling these occupations with study, mechanical labor, and composition. Shortly before his death he had all the ceremonies of his funeral performed, even taking his place in the coffin prepared for his body.—A man of the most remarkable executive ability, manifesting a power almost amounting to genius in the formation of his plans, and an almost unparalleled energy in carrying them out, Charles was nevertheless shortsighted in regard to the great questions of his time, and never freed his action from the narrowest motives of personal or family aggrandizement. "To gain the empire over Francis, and to leave to Don Philip a richer heritage than the dauphin could expect, were," says Motley in his masterly summing up of the emperor's character, "the great motives of the unparalleled energy displayed by Charles during the longer and more successful part of his career." His war with the reformation was rather against its political than its religious tendencies, and, until it was too late to oppose it with success, he was blind to the vast importance of the movement. Motley says of him that in spite of his rigid observance of religious rites, the bigoted intolerance he manifested toward the close of his life, and his harsh measures against the Protestants of the Netherlands, he was no fanatic. "He believed in nothing, save that when the course of the imperial will was impeded, and the interests of his imperial house in jeopardy, pontiffs were to succumb as well as Anabaptists." His private life, for a powerful monarch of that age, was decent and orderly; his greatest vice was gluttony, which in his retirement he carried to the utmost excess. In manner he was cold, formal, and repellent, without grace or the power of winning; but he often succeeded in persuading by the ingenuity of his arguments. Of his military and administrative talents Motley says: "He was inferior to no general of his age. He was the first to arm when a battle was to be fought, and the last to take off his harness. He was calm in great reverses. It is said that he was never known to change color except upon two occasions; a man of a phlegmatical, stoical temperament, without a sentiment, and without a tear; essentially a man of action, a military chieftain. Yet,

though brave and warlike, he was entirely without chivalry. He trampled on the weak antagonist, whether burgher or petty potentate. He was as false as water. He inveigled his foes who trusted to imperial promises by arts unworthy an emperor or a gentleman. He was not only greedy for additional dominion, but he was avaricious in small matters, and hated to part with a dollar. He knew men, especially he knew their weaknesses, and he knew how to turn them to account. He was indefatigable in the discharge of business; and if it were possible that half a world could be administered as if it were the property of a private individual, the task would have been perhaps as well accomplished by Charles as any other man."—Among the works treating specially of Charles V., the most important are those of Antonio de Vera, *Vida y hechos de Carlos V.*; Prudencio de Sandoval, *Historia de la vida y hechos del emperador Carlos V.*; Robertson, "History of the Reign of the Emperor Charles V." (London, 1769; Lanz, *Correspondenz des Kaisers Karl V.* (Leipsic, 1844-'6); and Charles's instructions to his son Philip II., translated into French by Teissier (the Hague, 1700). The MS. of a description of the capture of Tunis, in the handwriting of Charles, dated Tunis, July 23, 1535, and addressed by him to his sister Mary, regent of the Netherlands, has been discovered by M. Gachard, keeper of the Belgian archives. For the life of Charles V. after his retirement, the best original authorities are MSS. in the archives of Simancas. Upon these are chiefly founded the Gonzalez MS.; the *Chronique de Charles Quint*, by Pichot (Paris, 1854); the *Retraite et mort de Charles Quint*, by Gachard; Mignet's *Charles Quint*, &c.; Stirling's "Cloister Life of the Emperor Charles V.;" Prescott's appendix to Robertson's history; and Motley's "Rise of the Dutch Republic," vol. i.

CHARLES VI., emperor of Germany, and a pretender to the throne of Spain under the title of Charles III., the second son of the emperor Leopold I., and the last in the male line of the pure Hapsburg family, born Oct. 1, 1685, died Oct. 20, 1740. He was brought up in the expectation of succeeding to the Spanish throne, which he should by right have inherited from the childless Charles II., the reigning Hapsburg king. But the latter becoming ill, the question of the succession began to occupy the attention of several of the European governments, and became a subject of intrigue especially for the reigning families of France and Bavaria, both of which claimed the right to the inheritance through their descent in the female line; Louis XIV. being, like Leopold I., the son of a daughter of Philip III., and the Bavarian prince Joseph Ferdinand being a grand-nephew of Charles II. through Maria Antonia, daughter of the Spanish king's sister. The complications resulting from these various claims were somewhat simplified by the sudden death of Joseph Ferdinand in February,

1699, which left the French king untrammelled in his efforts to secure recognition of his alleged rights over the throne of Spain. The marquis d'Harcourt, Louis XIV.'s ambassador at Madrid, outmanœuvred Count Harrach, the German emissary, completely gained the ear of Charles II., and finally induced him to make a will declaring Philip of Anjou, the second grandson of Louis, to be heir to the Spanish throne, and confirming him and his heirs in the right of succession. This will was dated Oct. 2, 1700. On Nov. 1 Charles II. died at the capital, and 12 days later Louis XIV. declared that on the part of his grandson he accepted the possession of the kingdom of Spain. Philip, under the title of Philip V., was crowned at once, and at first met with no opposition, being recognized by all the European rulers excepting the emperor Leopold. But in the autumn of the next year, seeing renewed cause to fear Louis's encroachments, England and Holland decided to sustain the claims of Charles. On Sept. 7, 1701, a triple alliance was signed at the Hague between these two powers and Austria; and in 1702-'3 Prussia, the German empire, and Portugal joined the coalition. In 1703 Charles was proclaimed at Vienna king of the Spanish monarchy, under the title of Charles III. He went by way of Holland to England, whence he set sail with 12,000 men for Spain, nearly all parts of which were now held by the French. He landed at Lisbon, and with the assistance of the Portuguese attempted to invade Spain on its western frontier, but was repulsed by the duke of Berwick. In Catalonia and Valencia, on the opposite side of the peninsula, the population was supposed to be better inclined toward him; and in 1705, Peterborough having arrived at Lisbon with reinforcements from England, Charles embarked with his suite on the British fleet and sailed for the Mediterranean. Valencia received him with favor, and siege was laid to Barcelona, which was compelled by the genius and enterprise of Peterborough to surrender in October. Eight months later the English under the earl of Galway took Madrid, where Charles was again proclaimed king in June, 1706; but he remained at Barcelona and refused to go in person to receive the homage of his subjects at the capital, because he had not the equipage and retinue that he considered proper—an action very characteristic of the man. The war had now assumed a doubtful aspect, each side winning victories and experiencing defeat, and the capital twice changing hands between the contending armies. Charles personally manifested, or was permitted, but little activity. He remained shut up in Barcelona until the death of his brother the emperor Joseph, who had in 1705 succeeded Leopold, recalled him in 1711 to Germany. Charles now came into possession of all the countries that had been ruled by his father, which changed at once the whole aspect of affairs. Those of the great powers who had

entered the war to prevent the accumulation of too great possessions in the hands of the French king, now feared a similar massing of power under the government of Charles; and after the latter's coronation as emperor, which took place at Frankfort in December, 1711, they began, at first through secret negotiations and afterward openly, to withdraw from his support in the matter of the Spanish crown. Charles at first attempted with some success, with the assistance of Prince Eugene, to carry on the war in the Netherlands; but when in 1713 his former allies made peace with France by the treaty of Utrecht, and when the princes of the empire during the following year manifested the greatest reluctance to give him the aid he needed in his plans, he found himself compelled to yield, and concluded the peace of Rastadt in 1714, abandoning his chief claims, and securing only the Spanish possessions in the Netherlands and Italy. In this way terminated the war of the Spanish succession, which for more than 12 years had agitated all western Europe, and had employed the most famous military leaders of the time.—In 1715 Charles undertook the defence of the Venetian republic against the Turks, who had declared war against it, and Prince Eugene gained during the campaigns which followed the decisive victories of Peterwardein (Aug. 5, 1716) and Belgrade (Aug. 16, 1717), besides numerous minor successes. In 1718 the war was ended by the peace of Passarowitz, by the terms of which Belgrade, northern Serbia, and parts of Slavonia, Bosnia, and Wallachia were added to the imperial dominions. But Charles had only terminated one conflict because he found himself engaged in another. The Spaniards attacked Sicily, and sought to win back the Italian possessions they had conveyed to Charles at Rastadt. In repelling this attempt the emperor gained the alliance of England, France, and Holland; and the war made against these combined forces was of short duration. An English fleet drove the Spanish troops from Sicily, and after the fall of the Spanish minister Cardinal Alberoni, to whose schemes the conflict owed its origin, peace was made in 1720. By the death of his only son, Charles had been led to turn his attention to the question of the Austrian succession. Anxious to hand down his realms to his immediate descendants, he had in 1713 issued his pragmatic sanction, authorizing the transmission of the powers of his family through the female line, and appointing his daughter Maria Theresa as his successor. The consent of the daughter of his brother Joseph and of the princes of the empire was easily obtained; but France refused to recognize the new law, as did also Bavaria and Saxony, to the heirs of whose thrones Joseph's two daughters were married. To obtain the support of the principal European states in this matter now became one of the chief aims of Charles. His persistent efforts for some years failed to produce any decisive result, but

in 1725 he succeeded in gaining the alliance of Spain. A coalition for opposition to his plan was now formed by England, France, Denmark, and Holland; and when Charles had been successively joined by Russia and Prussia, whose support he purchased by immense sacrifices of territory and privileges, all the leading powers of Europe stood in two opposing parties. A great war seemed imminent, when through the intervention of the pope an arrangement was brought about, and signed at Vienna, March 16, 1731, by which, at the cost of still greater concessions on the part of the emperor, the pragmatic sanction was at last recognized by all. Spain's consent was purchased by the cession of Tuscany, Parma, and Piacenza; France was conciliated by the promise of Lorraine; England and Holland by the abolition of the commercial society of Ostend; and Augustus II. of Poland and Saxony, by the assurance of the succession to the crown of Poland of his son Augustus III. In accordance with this last promise, Charles, upon the death of Augustus in 1733, declared at once for his descendant; and in this he was joined by Russia; but France, Spain, and Sardinia supported the claims of Stanislas Leszczynski, the former king, who still had a strong party in the country of which he had once lost the crown. A new war now broke out; but Charles was not long able to cope with the great force brought against him. Russia aided him but little; the French overran and conquered Milan, nearly all Lombardy, and all Lorraine; the Spaniards possessed themselves of Naples and Sicily; and in order to secure his end, and give the succession in Poland to Augustus III., at the preliminary peace of Vienna, Oct. 3, 1735, he was obliged to permanently abandon all these portions of his territory. Equal misfortune attended him in a war which in the next year he declared against the Turks. In the three years of its continuance he lost nearly all the conquests made in his last conflict with the sultan; and when, at the solicitation of Maria Theresa, peace was again restored by the treaty of Belgrade, Sept. 18, 1739, his power was at a lower ebb than ever before; his armies were entirely demoralized; the finances of the empire were in a state of the greatest possible confusion; and the influence of the Hapsburgs had almost disappeared in the affairs of Europe.

CHARLES VII. (Karl Albrecht), emperor of Germany, born in Brussels, Aug. 6, 1697, died in Munich, Jan. 20, 1745. His father was Maximilian Emanuel, elector of Bavaria, and governor of the Spanish Netherlands. Joseph I., having taken possession of the elector's possessions in Bavaria, outlawed him, and detained his son as prisoner at Klagenfurt and Görz, where the young prince, however, enjoyed every advantage of education. Liberated in 1714, after the conclusion of the treaty of peace of Rastadt, Charles Albert was sent as commander of the troops against Turkey in 1716-'18. In 1722 he married a daughter of

Joseph I., having previously renounced all rights arising from this marriage to the Austrian dominions, and adhered to the pragmatic sanction. Four years afterward he succeeded his father as elector of Bavaria. His first act now was to protest against the pragmatic sanction, and after the death of Charles VI. in 1740 he put forth his claims to the Austrian succession, which had already been urged by his father, immediately on the accession of Maria Theresa. In the midst of the general opposition to which this accession gave rise, he succeeded in forming an alliance with France and Spain, at Nymphenburg, May 18, 1741. With the assistance of French troops he captured Linz, where he was proclaimed archduke of Austria; and advancing further, surprised and captured Prague, where he caused himself to be proclaimed king of Bohemia. Almost immediately afterward he was unanimously chosen German emperor, and proceeded to Frankfort, where, on Feb. 21, 1742, he was crowned by his brother, the elector of Cologne. The Hungarians, however, rose in favor of Maria Theresa, whose army occupied Munich, reconquered Upper Austria and Bohemia, and compelled Charles to resort to flight. The efforts of his general, Seckendorf, enabled him to return to Munich, April 19, 1743; but in June he was again expelled by the victories of Maria Theresa's troops. About the same time his allies, the French, were defeated near Dettingen by the English allies of Maria Theresa. Only by his alliance with Frederick of Prussia (May 22, 1744), who invaded Bohemia, and by the exploits of Seckendorf, was he enabled to turn the tide and regain his capital; a success which he accomplished just before his death.

IV. NAPLES.

CHARLES OF ANJOU, king of Naples and Sicily, count of Anjou and Provence, born about 1220, died in 1285. He was the youngest brother of Louis IX. of France, and married Beatrix, the heiress of Provence, thus becoming related to Henry III. of England and Richard of Cornwall, the king elect of Germany, who had married the two eldest sisters of Beatrix. He accompanied his brother in his first crusade, landing with him in Egypt in 1249, and being taken with him a prisoner by the Saracens. On his liberation he came back to Provence, where he had first to reestablish his authority in some of the large cities. He greatly assisted his mother, Blanche of Castile, in her regency during the king's absence in Palestine. On the death of the emperor Conrad IV. the kingdom of the Two Sicilies was offered to him by Pope Urban IV., in defiance of the rights of the Hohenstaufen. Crowned at Rome, he marched against Manfred, the natural brother of Conrad IV., who had been proclaimed king by the Sicilians. At Grandella, near Benevento, he won a great battle in 1266. Here his rival was slain, and he assumed at once over the reluctant Italians a power which

he maintained by unmitigated severity. The numerous adherents of the Hohenstaufens, aware of the popular feeling, invited young Conradin, son of Conrad, to Italy. This prince, then scarcely 16 years old, entered his hereditary states, where he was enthusiastically received. Everything seemed to promise him victory; his army was numerous and full of confidence; but Charles, with forces comparatively small, succeeded in defeating his opponent in 1268, at the battle of Tagliacozzo, and making him his prisoner. He subsequently had him executed on the principal square of Naples, after going through the mockery of a trial. The friends and adherents of the prince were also unmercifully dealt with, and the unpopularity of the conqueror was still further increased by the insolence of his French soldiery. In 1270 Charles sailed for Tunis, to join his brother Louis IX. in his second crusade. On his arrival he found Louis dead; but he succeeded in compelling the bey of Tunis to acknowledge himself his tributary. On his return he planned the conquest of the eastern empire, but his schemes were baffled by the insurrection commonly called the "Sicilian vespers," March 30, 1282. Sicily placed itself under the protection of Don Pedro of Aragon, and Charles tried in vain to reconquer the island. He was overpowered by the superior cunning of Pedro and the prowess of the admiral Roger de Loria. During this hard contest it was proposed that a duel should take place at Bordeaux between the two princes, a proposal eagerly accepted by Charles, although he was already 60 years old; but the offer was only made by Pedro to gain time, and the Aragonese did not appear on the appointed day. Charles repaired in haste to Italy, hoping to take revenge on the battle field; but on arriving at Gaeta he learned that his son had been defeated and taken prisoner in a naval engagement with the Aragonese admiral. This misfortune preyed heavily upon his mind; the inflexible warrior now became as wavering as he had been resolute. His death soon followed. He was succeeded by his son, Charles II., called the *Lame*, who began to reign in 1289, after his liberation. He also tried in vain to reconquer Sicily, and died in 1309.

CHARLES III., of Durazzo, king of Naples and Hungary, born in 1345, assassinated in Buda, Feb. 8, 1387. He was the son of Louis de Duras, or Durazzo, count of Gravina, who had rebelled against Queen Joanna I. of Naples, and died in prison. The queen had adopted Charles as her son, but in 1380 set him aside in favor of Louis duke of Anjou, father of Charles V. of France. Charles of Durazzo then entered into an alliance with Louis the Great, king of Hungary, the bitter enemy of Joanna. At the instigation of Pope Urban VI. and of the king of Hungary, Charles levied an army and set out to invade Naples. Passing through Rome, he was crowned by the pope, entered Naples in July, 1381, defeated the troops of the queen, and made a prisoner her fourth husband, Otho

of Brunswick. The queen also fell into his hands, and he urged her to confirm her former adoption of him; upon her refusal he shut her up in the castle of Muro, where she was put to death by his order, May 22, 1382. The arrival of the duke of Anjou brought on a desultory war which lasted two years, until the duke died, Oct. 11, 1384. Urban VI. was then at Nocera, in the kingdom of Naples, intriguing for the crown for his nephew. Charles, who was ill, invited Urban to come to Naples, but received for reply that it was customary for kings to come to popes, not for popes to go to kings. Margaret, the wife of Charles, in order to get rid of the pope, prohibited the bringing of wine to Nocera, whereupon Urban excommunicated Charles and his queen, and laid the kingdom under interdict, and ineffective hostilities took place. In 1385 the Hungarian magnates, discontented with the rule of Elizabeth, widow of Louis the Great, invited Charles to assume the government. He repaired to Hungary, and was crowned Dec. 31, 1386; but on the 5th of the following February he was stabbed by order of Elizabeth, and in her presence; he survived three days. As he was under excommunication, his corpse remained without sepulture till 1391.

V. SARDINIA.

CHARLES ALBERT (CARLO ALBERTO AMADEO), king of Sardinia, born Oct. 2, 1798, died at Oporto, July 28, 1849. The son of Charles Emanuel of Savoy-Carignan, of a younger branch of the royal family, and having consequently no hope of ever obtaining the crown except by the extinction of the direct line, he early adopted liberal principles, and was even affiliated with the carbonari. Being appointed regent, March 13, 1821, on the abdication of King Victor Emanuel, he proclaimed in Sardinia the constitution adopted by the cortes of Spain and appointed a provisional junta; but his plans were baffled by the marching of an Austrian army into Piedmont, and the rejection by King Charles Felix of all his measures. He then withdrew from Turin, resigned his office, and left the kingdom. In 1823 he served as a volunteer in the French army which under the duke of Angoulême invaded Spain, to crush its restored liberty; he was consequently charged with perfidy by his old associates. In 1824 he was allowed to return to Turin, and for a while in 1829 held the post of viceroy of the island of Sardinia. On the death of Charles Felix, the last of the elder branch, April 27, 1831, Charles Albert succeeded to the throne, and adopted a policy which was far from realizing the anticipations of the partisans of freedom. Some reforms took place; the feudal system was abolished; encouragement was given to agriculture, industry, and science; civil and criminal laws were reduced to a code; and the army received an entirely new organization, which greatly increased its efficiency; but these measures were mingled with many others hostile

to national liberty. On the accession of Pope Pius IX. in 1846 Charles Albert seemed to return to his former inclinations, granted a constitution to Sardinia, created a civic guard, amnestied the exiles of 1821, and granted more liberty to the press. On the outbreak of the revolution of 1848 he presented himself as the champion of Italian independence, and at once aided with his arms the insurgents in Lombardy and the duchies of Parma, Piacenza, and Modena, refusing French offers of aid with the words, *L'Italia farà da sè* ("Italy will help herself"). He fought successfully at first, defeating the Austrians at Pastrengo, April 30, 1848; Goito, May 29; and reducing Pizzighetone and Peschiera. But, ill supported by the Lombard troops, he was in his turn worsted at Custoza, July 25, by Marshal Radetzky, who had taken Vicenza, Treviso, and Padua, obliged to hastily retreat to and from Milan, and had to sue for an armistice, through which he lost all his former advantages. On the expiration of the truce, relying on the simultaneous operations of the Hungarians against the Austrians, he resumed hostilities; but his army, under Gen. Chrzanowski, was completely destroyed at Novara, March 23, 1849, and the hopes which Italy had placed in him were entirely lost. He then resigned the crown to his elder son, Victor Emanuel II., and retired to Oporto, where he died four months later.

VI. SAVOY.

CHARLES EMANUEL I., the Great, duke of Savoy, born at the castle of Rivoli, Jan. 12, 1562, died at Savillan, July 26, 1630. He succeeded his father, Philibert Emanuel, surnamed Ironhead, in 1580. His bold and enterprising spirit soon embroiled him in the wars of his time, and he successively entered into alliances with Spain, France, and the emperor of Germany, which he broke, however, as soon as it suited his interests. But he was possessed of remarkable talent, even of great scientific accomplishments, and distinguished himself by his courage in many a battle. In 1585 he married Catharine, the daughter of Philip II. of Spain. This connection, and some pretensions to the throne of France after the death of Henry III., made him the enemy of Henry IV., who had still to conquer his kingdom. Involved in war with Henry for the marquise of Saluzzo, and with the Swiss cantons of Geneva and Bern, he was compelled by a defeat at St. Joire (October, 1589) to an unprofitable peace; but he soon recommenced hostilities in alliance with the Catholic league, penetrated into Provence, occupied Barcelonette, Antibes, and Fréjus, and entered Aix as victor (November, 1590). This was but the commencement of a long war, which was carried on with varied success, and after a series of victories and defeats was terminated by the peace of Lyons (1601), which gave Saluzzo to Charles Emanuel in exchange for some small frontier districts ceded to France. He then made a sudden attack on

Geneva, but the enterprise failed; many of his soldiers were killed, others hanged as robbers. Afraid of the growing influence of Spain in Italy, he entered into alliance with France and Venice; but after the assassination of Henry IV. (1610), France concluded peace with Spain, abandoning the duke of Savoy. He then sought the alliance of the house of Hapsburg, and after the extinction of the ducal line of Mantua laid claims to Montferrat (1612). After the death of the emperor Matthias (1619), he became a candidate for the crown of Germany, but was beaten by Ferdinand II. Restless in his ambition (which also led him into schemes of conquest in Cyprus and Macedonia), he attacked Genoa (1624), and finally brought upon himself the enmity of all his former allies. The French occupied Pignerol, threatened Turin, and finally conquered Savoy. Broken by these disasters, the old Charles Emanuel died suddenly.

VII. SPAIN.

CHARLES I. See CHARLES V., Germany.

CHARLES II., king of Spain, son of Philip IV. and Marianna of Austria, born Nov. 6, 1661, died Nov. 1, 1700. Philip, dying when his son was but four years old, left the kingdom under the government of the queen and a council appointed by her. She chose for it men attached to her interests and holding her views, making her confessor, the grand inquisitor Neidhard, one of its leaders, but excluding both from this and all other important offices the second Don John of Austria, illegitimate son of Philip IV. Don John, whose military services had been of the greatest value to the Spanish throne, resented this neglect; and, assisted by the people, with whom his cause was popular, he marched with the army under his command against Madrid. The queen was compelled to dismiss Neidhard, to appoint John to the viceroyalty of Aragon, and to consent to several important concessions. In 1672 war with France added its evils to these internal disturbances; in 1674 Sicily was lost; and the Spanish kingdom was now brought by misgovernment to the worst condition it had known for many years. This moment Charles seized to make himself independent of the restraints of the regency; and in 1675, when barely 14 years of age, he assumed the control of affairs. Two years later he obliged his mother to retire to a convent, and made Don John his chief councillor. So long as the latter lived a great improvement was perceptible, and the affairs of the kingdom were skilfully conducted. In 1678 the treaty of Nimeguen was concluded with France; and although its terms were extremely hard, requiring the cession of Franche-Comté and several important towns in the Netherlands, it was only through the ability of Don John that Spain secured peace even on such conditions. On the conclusion of this treaty Charles received in marriage the niece of Louis XIV., Louisa, daughter of the duke of Orleans.

But Don John had barely brought the affairs of the kingdom into a tolerable condition when his death, Sept. 17, 1679, left them to fall into a worse state than before. Charles gave himself up to every kind of frivolity, paid little attention to the interests of the state, and allowed the conduct of the government to pass into the hands of unworthy favorites; his mother, returning from her retirement, regained much of her authority, and used it without scruple. In 1689 Queen Louisa, the only one who had exerted a good influence over the king, died; and the only strong opposing element in the king's conduct being thus taken away, he was left to advisers in the interests of Austria, who for the next few years ruled in such a way as to make Spain little more than a dependency of that empire. In 1690 Charles married Anna, widow of the elector palatine, and sister of the emperor of Germany; and thus became more than ever devoted to the party in European politics of which his council were already the allies. Even before the death of Louisa he had joined a coalition against Louis XIV., whose armies were threatening the Netherlands. But instead of his driving back the French in the north, they invaded his kingdom in 1694, and penetrated to Barcelona before the peace of Ryswick put an end to the war (1697). Charles, though twice married, was still without children; and, obliged to abandon the hope of direct descendants, he began to devote himself to the question of the succession to the Spanish throne. The complicated intrigues having their motive in the desire to gain this for one or another of the claimants (see CHARLES VI., Germany) occupied the last five years of his life, and ended, so far as he was concerned, in his making his will in favor of Philip of Anjou, who succeeded him under the title of Philip V.

CHARLES III., king of Spain and of the Two Sicilies, second son of Philip V. and Elizabeth Farnese, born Jan. 20, 1716, died Dec. 13, 1788. Since his elder brother Ferdinand would by right succeed to the Spanish throne, Charles's ambitious mother began almost at his birth to make schemes for gaining for him a separate kingdom; and it was through her efforts that the emperor Charles VI. was forced to grant, among the first concessions he made to secure Spain's consent to the pragmatic sanction, the possession of the duchies of Parma and Piacenza in Italy. To these duchies was to be added Tuscany so soon as the extinction of the line of the Medici, the last of whose race now ruled over it, should leave its throne vacant. This happened before Charles was 14 years old; and in 1731 his father sent him to the Spanish army in Italy, to occupy his new possessions. In 1734, during the war excited by the question of the Polish election (see CHARLES VI., Germany), he led the Spanish troops into Naples and subdued that country; he conquered Sicily also, and the emperor Charles VI. was compelled to confirm him in his

possession of both kingdoms, under the title of king of the Two Sicilies, before Spain would consent to give its full assent to the Austrian plan of succession, the recognition of which it was the aim of nearly all Charles VI.'s later treaties to secure. The first years of his reign, during the continuance of war, were occupied only with the defence of his kingdom; but on the return of peace he turned his attention to its internal administration, and governed with much wisdom and skill. In 1759 his brother Ferdinand VI. died, and Charles succeeded to the Spanish throne. He now conferred the kingdom of the Two Sicilies on his third son, Ferdinand, decreeing at the same time that it should not henceforth be united with Spain. In Spain Charles gratified the hopes excited by his excellent rule in Naples and Sicily. He undertook extensive reforms in the administration of the finances; introduced, in spite of the opposition of the clergy, many liberal provisions into the laws relating to education and religious administration; restricted the power of the inquisition, and put an end to the interference of the Jesuits in political affairs, finally banishing them from the kingdom (see ARANDA); reestablished the coinage on the former basis; encouraged the institution of a bank at Madrid; and established societies for the promotion of the arts and sciences. In the war which ended with the recognition of American independence, Spain took part against England, but with small success. An attempt against Algiers also attained but slight results; and Charles's reign is rather remembered for its internal improvements than for its foreign policy.

CHARLES IV., king of Spain, born in Naples, Nov. 12, 1748, died in Rome, Jan. 19, 1819. The son of Charles III., he succeeded to the throne in 1788, having married at an early age his cousin, Maria Louisa of Parma, by whom he was entirely controlled. When Manuel Godoy, a handsome private in the body guards, became her lover, she contrived to make him the friend of her husband; and she succeeded so well that they lived together on the most intimate terms, the favorite of the queen becoming also the favorite of the king. He was always ready to confer new favors upon Godoy; raised him very rapidly to the rank of a lieutenant general, and bestowed upon him the title of duke of Alcudia and the office of minister of foreign affairs. Complications arose with the French republic, owing to the efforts of Charles to save the life of his cousin, Louis XVI., whose execution he resented by declaring war against France. His army, however, was soon worsted, and he was happy to conclude in 1795 a treaty of peace at Basel. This treaty was signed by Godoy, who then assumed the title of "Prince of the Peace." In consequence of this alliance with France, Charles became involved in a war with Portugal and England. The hostilities against the former country did not last long, nor were they severe; but in the contest with the lat-

ter, the Spanish navy received a deadly blow at the battle of Trafalgar (Oct. 21, 1805). Napoleon, who found a pliant tool in Godoy, finally resolved on deposing Charles IV., who also had an enemy in his own son Ferdinand. The young prince, whose bad qualities were still unknown to the nation, gained universal favor by his opposition to Godoy and the French rule, and used his influence to annoy his father. Charles, disgusted with his son's conduct, and tired of the French domination, resolved to retire to Spanish America; but on the very day he intended leaving his royal residence at Aranjuez, March 18, 1808, he was stopped by a tumult of the populace instigated by Ferdinand. The rage of the people was now directed against the queen and Godoy. In order to save Godoy's life, Charles abdicated (March 19) in favor of Ferdinand, but a few days later sought to withdraw the abdication. Napoleon put an end to the feud between father and son by deposing them both. Charles and Ferdinand were taken to Bayonne, where Napoleon was to pronounce between them as an umpire. As soon as the emperor got them in his power, he obliged Ferdinand to restore the crown to his father, who in turn relinquished it to Napoleon. This episode was the turning point of the fortunes of Napoleon. Charles received in exchange for his crown the castle of Compiègne, surrounded by a forest abounding in game, with a yearly pension of 6,000,000 francs. Notwithstanding the allurements of Compiègne, Charles went to Marseilles; and in 1811 he was permitted to repair to Rome, in company with his wife and Godoy. After the fall of Napoleon, Ferdinand having given dissatisfaction to the Spaniards, a proposition was made to Charles to renew his claims to the crown; but he refused, his only desire being to spend his latter years in retirement in the company of his wife and her paramour. The former having died in December, 1818, grief preyed so much upon his mind that he died within a month afterward.

VIII. SWEDEN.

CHARLES IX., king of Sweden, fourth son of Gustavus Vasa, born in 1550, died Oct. 30, 1611. Eric XIV., successor of Gustavus, excited the dislike of the people, and his brothers John and Charles united against him; he was deposed, and succeeded by John, who died in 1592. His legal successor was his son Sigismund, who had been elected king of Poland, being the son of a princess of the house of Jagiello. Sigismund being a Catholic, and bitterly hostile to Lutheranism, which had been introduced into Sweden by Gustavus Vasa, Charles, by the consent of the senate, assumed the government, and a decree was passed that Lutheranism should be the only religion of Sweden, and that Sigismund should not be recognized as king until he had signed the decree. This he did, and was crowned in 1593, but he became obnoxious on account of the favor which

he manifested to Catholicism. There was also a party, led by Charles, opposed to a union of the crowns of Poland and Sweden. A war ensued. Sigismund was defeated, and resigned the crown of Sweden in favor of his young son Ladislas, who was sent to Sweden to be educated as a Protestant, under the eye of Charles, who was appointed regent. After a while Sigismund renewed his pretensions, and was opposed by Charles, to whom the crown of Sweden was offered. This he at first declined, and made propositions to Sigismund, which were rejected, and the war broke out afresh. At length the states again offered the crown to Charles, making the succession hereditary in his family. He accepted, and the coronation took place in 1604. Charles carried the war into Poland, but there had little success. He also became involved in hostilities with Russia, where his general, De la Gardie, gained important advantages. This alarmed Christian IV. of Denmark, who declared war against Sweden, and captured several strong places. Charles, in spite of his age and infirmities, challenged Christian to mortal combat, which was contemptuously declined. Charles died soon after, leaving the war with Denmark and Russia to his son Gustavus Adolphus. Charles IX. was a monarch of considerable ability, though harsh and cruel in character. He instituted a new code of laws, founded several cities, established the university of Gothenburg, and in other ways did much to promote education. He wrote a rhymed chronicle of Sweden, which is often quoted by historians. His letters to Henry IV. of France, the elector palatine, and the landgrave of Hesse, on the means of making peace with Sigismund III. of Poland, have been published in German (4to, Amsterdam, 1608).

CHARLES X., Gustavus, born at Nyköping, Nov. 8, 1622, died at Gothenburg, Feb. 13, 1660. He was the son of John Casimir, prince palatine of Deux-Ponts, and of Catharine, daughter of Charles IX. and sister of Gustavus Adolphus of Sweden. He was carefully educated at the university of Upsal, and afterward travelled in Germany, France, and Switzerland. Gustavus Adolphus, falling at the battle of Lützen (1632), left his kingdom to his infant daughter Christina. The Swedes, however, still carried on the thirty years' war in Germany, and Prince Charles in 1642 entered the Swedish army, and served with distinction under Torstenson. In 1648 he was appointed generalissimo of the Swedish forces in Germany. But the war having in that year been ended by the treaty of Westphalia, Charles returned to Sweden, where he was received with great favor, and was declared heir apparent to the crown. He became enamored of his erratic cousin Queen Christina, who however made light of his attachment, and refused to marry him, but in 1654 abdicated in his favor, and Charles was crowned June 16. He found his kingdom in great disorder. Most of the revenue was absorbed by the pension set-

tled upon Christina, and the interval of peace had impaired the military spirit of the nation. John Casimir, king of Poland, son of that Sigismund who had been set aside in Sweden in favor of Charles IX., made pretensions to the Swedish crown. Charles thereupon invaded Poland, gained several victories, captured Warsaw and Cracow, and in three months made himself master of all Poland, John Casimir taking refuge in Silesia. Frederick William, elector of Brandenburg, had made incursions into ducal Prussia, which gave umbrage to Charles, who marched against him, and compelled him to acknowledge himself a vassal of Sweden. The rapid success of the Swedes alarmed all Europe, and John Casimir, assured of support, renewed the war. In the depth of winter Charles marched again into Poland, gained a great victory over Czarniecki, and then moved upon Dantzic. The Poles rallied, and, aided by the Tartars, recaptured Warsaw, whither Charles and the elector of Brandenburg marched; and in July, 1656, a battle lasting three days was fought near that city, in which the Swedes were finally victorious. Charles rewarded the services of Frederick William by recognizing him as independent sovereign of Prussia. France, England, and Austria grew jealous of Sweden, the czar Alexis made some hostile movements, and Frederick III. of Denmark declared war against her, and invaded the duchy of Bremen. Charles, leaving a small force in Poland, marched into Holstein, sending Wrangel with another corps to Bremen, and the Swedes gained considerable successes in both directions; but a naval battle, lasting two days, was fought with no decisive result. Charles was now without a single ally. Poland was in full insurrection; Russia, Austria, and Denmark were in arms; Turkey showed signs of hostility; and the elector of Brandenburg declared against Sweden. Charles resolved upon a sudden blow against Denmark, his nearest enemy. In January, 1658, at the head of 20,000 men, he appeared upon the shore of the Little Belt, which was now frozen over. He crossed upon the ice to the island of Fünen, where he cut to pieces a Danish force of 4,500, and then advanced to Langland, Laaland, Falster, and finally to Seeland. The Danes were struck with terror at this unexpected invasion, and gladly accepted the terms offered by Charles, giving up some important places on the Belt. Charles also made peace with the Russians, ceding to them several conquests which they had made. In 1659 the king of Denmark began to show signs of hostile purposes, and Charles resolved to anticipate his overt action. He suddenly appeared with his fleet before Copenhagen. A vigorous assault by the Swedes was repulsed, and a blockade was thereupon established; but the Dutch were unwilling that either Sweden or Denmark should have entire control of the northern waters, and the Dutch fleets supplied provisions to the besieged capital. Charles went back to

Sweden to raise fresh subsidies; but while engaged in strengthening his armies and fleets, he died suddenly of fever.—Charles X. was a ruler of great ability and unbounded ambition. He aspired to the sovereignty of the north of Europe. He purposed to extend the boundaries of Sweden from the gulf of Finland and Bothnia to the North sea; and according to the reports of the French ambassador, he cherished designs still more vast: when he had made himself master of the north, he would, like a second Alaric, descend upon Italy with a great army and navy, and bring Rome again under the power of the Goths. His life has been written by Pufendorf, *De Rebus a Carolo Gustavo gestis* (2 vols., Nuremberg, 1696); and in Swedish by Lundblad, who also translated the work into French (1825). He was succeeded by his infant son Charles XI. (born in 1655, died in 1697).

CHARLES XII., born in Stockholm, June 27, 1682, killed at the siege of the fortress of Frederikshald, Norway, Dec. 11, 1718. He was the eldest son of Charles XI. (1660–1697), a peaceful prince, who improved the internal condition of his kingdom, opened the succession to females, and left the crown with a full treasury to his son. Charles was well educated under the care of his father, and early acquired great facility in speaking French, German, and Latin; he had also a more than ordinary knowledge of history, geography, and mathematics, especially of the latter science; and it is said that his favorite work was Quintus Curtius's account of the victories of Alexander the Great, whose career his own so much resembled. He was but 15 years old when he was declared by the estates to have attained his majority, and succeeded to the throne (1697). At first he showed little inclination or aptitude for business, devoting himself mainly to bear hunting. But before he had been two years on the throne a league between Russia, Denmark, Saxony, and Poland was brought about by Patkul, a Livonian noble, who had been ill-used by Charles XI., and, flying to the Russians, had been condemned to death *in contumaciam*. Peter I. of Russia sent Patkul as his ambassador to Augustus of Saxony and Poland, and, taking advantage of the quarrel of Sweden with Livonia, occupied the shores of the gulf of Finland. Denmark had also been rendered hostile by the annexation of Schleswig-Holstein to Sweden, and the Danish troops invaded the territories of Frederick, duke of Holstein-Gottorp, who had married Hedwig Sophia, the sister of Charles. Frederick repaired to Stockholm to demand the aid of Charles, who entered fully into the enterprise, obtained by the treaty of the Hague the aid of England and Holland, and assumed the initiative with great energy. In May, 1700, he embarked at Carlserona for the island of Zealand, designing to attack Copenhagen with a fleet of 30 ships of the line, besides transports, assisted by a Dutch and English squad-

ron. In his first engagement Charles gave evidence of the impetuous courage for which he was afterward distinguished; for, on nearing the place of disembarkation, he leaped into the sea, and was the first man on the enemy's soil. Copenhagen was bombarded by the fleets, and would have been invested and closely besieged, when further operations were terminated by negotiations, which had for their result the signing of a separate peace at Travendal (Aug. 8, 1700), Frederick IV. of Denmark deserting the coalition, and resigning Schleswig-Holstein to the house of Gottorp. In the mean time a Polish army had overrun Swedish Livonia, and laid siege to Riga, while Peter of Russia besieged Narva. The sword which Charles now drew was never again to be sheathed. From this time forth he affected the habits of an old campaigner; wine was banished from his board; coarse bread was often his only food, and he not unfrequently slept on the ground, wrapped in his heavy cloak. His dress, too, at a period when men of gentle birth paid the greatest attention to their apparel, and especially to the hair, was affectedly coarse and ultra-military. Without awaiting reinforcements, or losing any time, in the depth of winter he proceeded by forced marches across Livonia into Esthonia, where he attacked the Russian besieging army before Narva, with but 8,500 men against 50,000, and utterly defeated it, Nov. 30, 1700. Instead of following up his success, he turned aside to attack the Polish and Saxon armies, which were posted in a strong position on the Düna. On the first attack his men were repulsed with some loss; but rallying them in the middle of the stream, he reformed them in the channel of the river, and led them to a decisive victory. Shortly after this Augustus sent his mistress, Aurora von Königsmark, reputed the most beautiful woman in Europe, in the hope of entangling him in some intrigue; but Charles refused to see her. Another army was brought against him under the Saxon general Riese; but in vain, for Charles was everywhere victorious. At Kliszów, July 19, 1702, he gained another victory, which would have been decisive had not Charles been detained by a broken leg at Cracow, which delayed the campaign so much that, although he was closely pursued for four days by the Swedes under Rehnsköld, Augustus continually escaped, and afterward found a respite, owing to the invasion of Finland by the Russians, which required the whole attention of Charles till 1705. He thus wasted time in petty struggles with Poland and Saxony, allowing the young and growing colossus of the north to recuperate itself at its leisure, when he might have crushed the embryo power which in the end crushed himself. At this time, however, his thoughts seem to have been solely fixed on placing another king on the throne of Poland, young Sobieski having been surprised by Augustus at Ohlau in Silesia and carried into Saxony. Stanislas Leszcynski was

therefore elected king by the partisans of Sweden and Poland; and, although Rehnsköld was at first held in check by the manœuvring of Von Schullenburg, whose retreat across the Oder is famous in the annals of war, yet on his advancing to aid the czar, whom Charles was driving out of Lithuania, he was completely routed at Fraustadt (February, 1706) by his former opponent; in consequence of which defeat Augustus fell back upon Russia, and Charles, dashing rapidly across Silesia into Saxony, was there received with enthusiasm. This bold step so terrified Augustus that he sent his two principal councillors from Poland, with full powers to treat with Charles; but when the treaty had actually been signed, having been compelled during the progress of secret negotiations to assist his Russian ally at Kalisz, where Peter was victorious, he was so much elated that he declared the report that peace had been concluded between himself and Charles false in every particular. The declaration did nothing, however, to eject Charles from Saxony, of which he kept absolute possession, and in which Augustus was held in contempt and detestation. The Saxon was soon compelled to lower his pretensions, and to meet Charles in conference at Altranstädt, where peace was definitely concluded (Sept. 24, 1706). By it Augustus resigned all claims to the throne of Poland, and surrendered to the conqueror young Sobieski and the unhappy Patkul, against whom the vengeance of Charles was particularly excited, and whom he caused to be broken on the wheel. Charles now took up his residence in Saxony, and acted as though he was its sovereign, recruiting his armies from its subjects, and compelling the emperor Joseph I. of Germany, who had dispossessed his Protestant subjects of 125 churches, which had been given up to the Jesuits, to restore those which had been confiscated, and to permit the erection of six new ones. The emperor was at this time hard beset by his enemies in the war of Spanish succession, and the empire, if Sweden had joined the coalition against it, would have been in peril of total ruin. In order to avert this calamity, Marlborough was sent to visit the Swedish conqueror. The courtly talents of the handsome and polished Englishman were not exerted in vain. Charles was persuaded to withhold his aid from the coalition, and to turn the weight of his arms and military genius against Russia. In September, 1707, he invaded that country at the head of 43,000 men, marching almost by the very route which Napoleon followed with ten times the number of troops a little more than a century later, and shared almost identically the same fate. Charles crossed the Beresina at Borisov, and stormed the Russian lines at Golovtchin, wading the river Vabis, in which he sunk up to the neck, at the head of his forlorn hope. Thence he pursued the enemy with such inconsiderate haste and rashness that he involved himself and his army in forests and morasses.

His artillery was lost in the swamps, and his men died of hunger, while he was yet advancing. But he pressed resolutely onward, the enemy wasting the country before him. Gen. Löwenhaupt, who was attempting to join him with reënforcements from Sweden, was waylaid and defeated, after a desperate conflict which lasted during three days, by the czar in person, at Liesna; notwithstanding which, he succeeded in joining his master at the head of 6,000 men. Up to this time it had been the plan of Charles to strike direct at Moscow; but when he reached Smolensk he was persuaded by Mazeppa, the hetman of the Cossacks, to turn his line of march toward the Ukraine, where the hordes were not as yet reconciled to the Russian yoke, and where they had promised to aid him. But Peter laid waste the country, constantly retreating before him and refusing to deliver battle; and Mazeppa, who was proscribed, failed to aid him until he forced his way, with fearful loss of life from cold, hunger, and fatigue, in the depth of the winter 1708-'9, as far as Gadatch upon the Dnieper in lat. 52°, where he retired into winter quarters with the intention of attacking Poltava, a strong town on the river Vorskla, with an abundance of all provisions and supplies of which his army was in want, in the commencement of spring. Before that time arrived, however, his forces were so fearfully reduced that Peter, who since his defeat at Narva had completely reorganized his army, resolved to fight, and appeared at the head of 70,000 men, at the moment when Charles was about to invest the city. It so happened that while reconnoitring the advance of the enemy Charles was dangerously wounded in the thigh, and was obliged to limit his exertions on the day of battle, July 8, 1709, to issuing his commands from a litter instead of directing their manœuvres himself, and charging in person at their head. All advantages, however, without counting this, were in favor of the enemy: vast superiority of numbers, better equipment, perfect condition of men and animals, and a superb artillery. There was reason enough why the Russian should win the day, and he did so completely. Charles escaped with extreme difficulty, with a handful of followers, into Turkish territory, old Mazeppa adhering faithfully to his fallen fortunes. The last salvo was fired by Prince Maximilian Emanuel of Würtemberg, who commanded a Swedish regiment. He was taken prisoner and treated with extreme distinction by the czar. The Swedish division of Löwenhaupt was overtaken and compelled to surrender on the Dnieper, and Charles, escaping to Bender on the Dniester, a strong fortress which was then in Turkish territory, where he was hospitably received and allowed to fix his residence by the Ottoman Porte, employed the whole power and energy of his mind to bring about a war between Turkey and Russia. This he succeeded in doing, and the grand vizier, taking the field in 1711

at the head of 200,000 men, shut Peter up on the Pruth; and his affairs seemed utterly ruined when his yet unacknowledged wife, afterward empress as Catharine I., bribed the grand vizier with all her jewels to allow the Russians to escape. That day was decisive of the fall of Charles and the rise of Russia. Charles, who had been greatly aggrieved that to him had not been assigned the chief command of the Turkish army, galloped impatiently into the camp, but too late to prevent the escape of the czar. Frustrated as he was and severely mortified, the king of Sweden still continued year after year, till 1713, to linger at Bender, incessantly employed in endeavoring to awaken the Turkish government to a consciousness of the danger of allowing the Russians to consolidate their rising power, and constantly hoping that he had succeeded, but ever hoping in vain. He effected the overthrow, by the intrigues of the agents whom he employed at Constantinople, of four successive grand viziers, and felt justified in his long delay by the reasonable hopes he entertained of placing himself at the head of a powerful Turkish army. In the mean time Livonia and Esthonia fell a prey to Russia, immediately after the calamity of Poltava. Riga surrendered. Courland became the property of Peter, who caused its duke to marry his niece Anna Petrovna, and then designedly and deliberately drank him to death. Pomerania was next invaded. The Saxons seized the whole of Poland on the flight of Stanislas, who, deserted by all his adherents, joined Charles in Turkey; the allied forces of Saxony and Russia made themselves masters of all Swedish Pomerania, with the exception of Stralsund and Wismar; and after the war had been carried on with the utmost cruelty, Stade, Altona, Garz, and Wolgast being burned to the ground in the dead of winter, and most of their inhabitants perishing of hunger and cold, Prussia was induced to join the anti-Swedish league by the promise of the future possession of Stettin. But about this time events took place in Turkey which nearly altered the whole state of affairs in Europe. The Russian agents having at length persuaded the sultan that the residence of Charles at Bender was dangerous to his safety, as he was plotting, they said, to attack Turkey from Poland should he succeed in establishing Stanislas on that throne, he received intimation that he must leave Bender; and on his positively refusing to do so, orders were issued to the seraskier of that place to bring him, dead or alive, to Adrianople. Refusing to submit, he barricaded his house, and, with the 200 or 300 men who composed his personal retinue, defended it until, the roof taking fire, he was forced to sally out, when his spurs becoming entangled, he fell, and was mastered and made prisoner (Feb. 12, 1713). He was removed to Demotika, near Adrianople, where, obstinate as ever, he remained ten months in bed, feigning sickness, until, becoming satisfied that he

could expect to obtain nothing from the Porte, he sent off a parting embassy to Constantinople, in order to conceal his intentions, and then taking horse, in disguise, by night, travelled through Hungary, Austria, Bavaria, the Palatinate, Westphalia, and Mecklenburg, in order to avoid the Saxons and Prussians, and reached Stralsund during a dark night (Nov. 22, 1714). The moment it was known that Charles was in the city, it was invested by a combined army of Danes, Saxons, Russians, and Prussians. It was defended by Charles with extraordinary skill and talent for nearly a year; but despairing of receiving aid from without, he was forced to abandon it, Dec. 15, 1715, when he retired to Lund in Scania, where he set himself to defend his coasts. For the remainder of his reign the war was carried on for the most part by sea, and generally to the prejudice of the Swedes, though not without Charles at times making dangerous efforts against Norway. At this time his principal friend and adviser was Baron Görtz, the minister of Holstein, who all but succeeded in breaking up the anti-Swedish league, which had just been joined by George I. of England. It was the policy of Görtz to gain over Peter the Great by any concession which might be needful, by his aid or connivance to conquer Norway, and thence, with the aid of a preconceived Jacobite rising, to land in Scotland, and dethrone George I. in favor of the pretender. A treaty had been agreed upon by which Peter should retain his conquests on the gulf of Finland, Stanislas should be replaced on the throne of Poland, and Charles should be married to Anna Petrovna, the widow of the duke of Courland. Accident dissolved the whole scheme. A Swedish despatch fell into the hands of the Danes. Denmark dreaded the union of Russia and Sweden; Saxony saw that she would lose Poland; Hanover, that her projects upon Bremen and Verden, Prussia that hers on Stettin would fail. Frederick of Hesse would no longer be heir to the crown of Sweden; while the power of Charles by so great a marriage would swell to a height dangerous to the aspirations of the Swedish aristocracy. A small Swedish force under Armfeldt had perished from cold while crossing the mountains which separate Norway from Sweden, and another, commanded by Charles in person, was besieging the fortress of Frederikshald in the south of Norway, when he was shot through the head while standing in the trenches at night exposed to the enemy's fire. It was generally supposed that he was assassinated by an emissary of the party opposed to his projects, and the question of his death gave rise to a discussion continued for many years, and resulting in the publication of more than 200 books and pamphlets. The controversy was finally settled by an inquest held at Stockholm in 1859 by the Swedish government, when the body of Charles was examined by three eminent physicians in the presence of King Charles XV., his ministers, the royal

princes, and other persons of note. The inquest after careful investigation decided that the fatal wound was inflicted by a musket ball fired from the besieged fortress. His tomb is in the chapel opposite to that where the remains of Gustavus Adolphus are interred, in the royal mausoleum in the Ridderholms church in Stockholm. The walls are decorated with trophies of his various battles, including a standard taken with his own hands in Poland. The hat, clothes, and sword worn by him at the time of his death are preserved in the chapel. Ulrica Eleonora and her husband Frederick of Hesse succeeded him on the throne of Sweden. Görtz, for his endeavors to preserve the integrity of the kingdom, was sentenced to the block. Sweden was as fatally dismembered, in order to secure the succession of a false heir to her crown, as she could have been by the utmost spite of her enemies.—See Norberg, *Konung Carls XII. historia*; Adlerfeld, *Histoire militaire de Charles XII.*; Lundblad, *Konung Carls XII. historia* (Stockholm, 1835-'40); German translation, Hamburg, 1835-'40); and Voltaire, *Histoire de Charles XII.*

CHARLES XIII., born Oct. 7, 1748, died Feb. 5, 1818. He was the second son of Adolphus Frederick and Louisa Ulrica, sister of Frederick the Great of Prussia. Destined from his birth to fill the high office of lord high admiral of Sweden, he received a naval education, and made several cruises in his youth. In 1765 he became president of the society of sciences at Upsal, and in 1770 commenced the tour of Europe. On the death of his father, and the accession of his brother Gustavus III. to the throne of Sweden (1771), he was recalled, and played a very important part in the revolution of 1772, by which the power of the kingdom was vested in the person of the king, with the consent of the estates. This was effected mainly by the establishment of the order of Vasa, and by the organization of clubs and committees among the young officers of the army and navy in the confidence of the king. It was agreed that the brothers of the king should superintend and commence the movement in the country, while the king himself should attend to the management of the affair in the capital. The revolution broke out by the pretended siege of Christianstad, in August, 1772, by Prince Charles, in which no one was injured; and the whole business was so admirably managed that without the spilling of a drop of blood the country was delivered from the tyranny of the nobles, and the king restored to the authority of his ancestors. Shortly after these events Prince Charles was created duke of Södermanland, and appointed governor general of Stockholm. But war soon breaking out against Russia, which persisted in fomenting dissensions in Sweden, he returned to his old profession, assumed the command of the Swedish fleets, and defeated the Russians in a naval engagement in the gulf of Finland; in reward for which he was raised to the governorship. On the murder of

Gustavus III. in 1792 he was appointed regent; in which situation, at a highly critical period, he preserved the kingdom for his nephew Gustavus in its constitutional form, kept it externally and internally at peace, and united for the protection of navigation in the northern seas with the Danes. In 1796 he resigned his power to Gustavus, who ascended the throne under the title of Gustavus IV. Adolphus. After his nephew's accession Prince Charles retired into private life, passing his time in literary and scientific pursuits, and appeared no more in public affairs until, Gustavus having become a religious fanatic, a revolution broke out in 1809, by which he was deposed and his uncle placed at the head of affairs, first as administrator of the realm, and afterward (June 6, 1809) as king of Sweden. His reign was cast in stormy times, during the career of Napoleon; but he conducted the affairs of state with such consummate ability and prudence, that while almost every other European kingdom was in some degree a sufferer from the long-protracted warfare, Sweden not only suffered no loss, but received Norway at the restoration of peace as a compensation for the loss of Finland. Charles XIII. had married in 1774 Hedwig Elizabeth Charlotte, princess of Holstein-Gottorp; but having no heir, he had adopted Prince Christian of Holstein-Sonderburg-Augustenburg as his successor; and on his dying prematurely, chose Bernadotte to succeed him (1810).

CHARLES XIV. JOHN. See BERNADOTTE.

CHARLES XV., king of Sweden and Norway, born May 3, 1826, died at Malmö, Sept. 18, 1872. He succeeded his father Oscar I., son of Bernadotte, July 8, 1859, and was crowned in Stockholm May 3, and at Drontheim, Norway, Aug. 5, 1860. The great parliamentary and many other liberal reforms were instituted in Sweden during his reign, and he was extremely popular with all classes on account of his enlightened policy as well as his personal qualities. He was an excellent sportsman and artist, an accomplished poet and writer, and author of several works. During the Franco-German war of 1870-'71, he sympathized with France, but prudently refrained from committing his state. His death was mourned in Sweden and Norway as a great public calamity. His wife Louise, a Dutch princess, died March 30, 1871. Their only child, the princess Louise, married the crown prince of Denmark, July 28, 1869. By his will he left to the state most of his artistic collection, including the portion of the paintings relating to Scandinavia; the collection of arms to be placed in the national museum, the rest to remain in the chateau of Ulriksdal. He was succeeded by his brother Oscar II.

IX. WÜRTEMBERG.

CHARLES I. (KARL FRIEDRICH ALEXANDER), born March 6, 1823. He married July 13, 1846, the Russian grand duchess Olga, daughter of the emperor Nicholas, and a sister of the present czar. He succeeded to the throne

June 25, 1864, on the death of his father William I. He sided with Austria in the German war of 1866, but after the battle of Sadowa concluded a secret military treaty with Prussia, and took part on her side in the Franco-German war of 1870-71, joining the new German empire at the close of 1870.

OTHER PRINCES.

CHARLES, archduke of Austria, third son of the emperor Leopold II., younger brother of Francis I., and uncle of Ferdinand I., born in Florence, Sept. 5, 1771, died April 30, 1847. Of weak constitution and sickly, he seemed to promise little, but was soon attracted by military subjects, and became fond of geometry and other serious studies. He was 20 years old at the time of the first war of the emperor, his brother, against France (1792). Under Hohenlohe he took part in the battle of Jemmapes against Dumouriez, and afterward commanded the van of the prince of Coburg, distinguishing himself in the engagements of Aldenhoven and Neerwinden, in which the French were defeated. Belgium having been reconquered, he was appointed its governor general, March 25, 1793. In 1794 he had a part of the Austrian command in the battles of Landrecy, Tournay, Courtray, and Fleurus, against the victorious army of Pichegru. When the Netherlands were lost, he retired for some time to Vienna to restore his impaired health. In 1796 he took the field again as field marshal of the empire, and commander-in-chief of the Austrian army on the Rhine; and his victories over Jourdan at Neumarkt, Teining, and Amberg soon compelled Moreau, who had advanced as far as Munich, to undertake his famous retreat; the French were driven over the Rhine, and only maintained in their possession the bridges of Hüningen and Kehl. Both these positions Charles attacked and took in the following winter. But while things were going on successfully in Germany under his command, the French under Bonaparte were everywhere victorious in Italy, and were rapidly advancing toward the heart of Austria; and when Charles was sent there to check their progress, the victorious young general, imitating the words of Cæsar, could say, "Hitherto I have had to combat armies without a commander; now I have to combat a commander without an army." Charles was compelled to conclude the preliminary treaty of Leoben, April 18, 1797, which was soon followed by the peace of Campo Formio. Having lived for some time in Bohemia as governor of that kingdom, he was again called to arms after the violent breaking off of the congress of Rastadt (1799), and again defeated the French under Jourdan, who had crossed the Rhine, in the battles of Ostrach and Stockach. Dissensions between him and the commanders of the allied Russian troops checked his successful operations, and after the defeat of Korsakoff by Masséna at Zürich, he had again to guard the Rhine. Bad health

compelled him in March, 1800, to resign his command to Kray, and to retire to Bohemia. He was not yet restored when he had to hasten again to the defence of the empire of his brother, which, by the admirable marches of Napoleon over the Alps and of Moreau through Germany, was brought to the brink of ruin. The armistice of Steier concluded by him with the latter was the preliminary of the peace of Lunéville (1801). His great services were now recognized by his appointment as president of the aulic council of war at Vienna, as well as by a proposition made at the diet of the German empire to reward him with a statue and the title of savior of Germany; which honors, however, he refused to accept. In 1805 he commanded the Austrian army in Italy against Masséna, but his victory at Caldiero (Oct. 29-31) was of little avail, as Napoleon after the surrender of Ulm was rapidly advancing toward Vienna. The hasty retreat of the archduke Ferdinand to Bohemia, and the battle of Austerlitz, compelled Francis to the peace of Presburg (Dec. 25). Charles was now made generalissimo of all the Austrian armies, and minister of war, with unlimited power, which he used for the reorganization of the forces of the empire and the creation of a strong reserve and militia. In 1808, after the abdication of Charles IV., king of Spain, the provinces of Catalonia and Aragon called him to the throne of Spain and India, and an English frigate was sent to carry him from Trieste, but was sent back with his thanks. In the war of 1809 he commanded in Bavaria, while his brothers John and Ferdinand led the armies in Italy and Poland; he advanced as far as Ratisbon, but Napoleon's victories at Thann, Abensberg, Landshut, Eckmühl, and Ratisbon (April 19-23) compelled him to retreat. Having, however, received new reinforcements, he checked Napoleon, who had taken Vienna, in the battle of Aspern and Essling (May 21, 22). This advantage brought little more than glory, and he was defeated at the battle of Wagram, July 5, 6, and retreated continually fighting to Znaym. An armistice, and soon after the peace of Schönbrunn, put an end to the campaign. Charles was wounded, and feeling at the same time personally mortified, he resigned on July 30 his military command and all his offices, and retired to Teschen, whence he afterward went to Vienna. After the return of Napoleon from Elba, he again served for a short time as governor of Mentz; but this was the last act of his public life. He married in 1815 Henrietta, princess of Nassau-Weilburg, and became the father of a numerous family, among whom he lived in quiet retirement. An equestrian statue of him was erected in Vienna in 1860. He is known in military literature especially by his *Grundsätze der Strategie, erläutert durch die Darstellung des Feldzugs von 1796 in Deutschland* (3 vols., Vienna, 1814), and *Geschichte des Feldzugs von 1799 in Deutschland und der Schweiz* (2 vols., 1819). In 1862 a col-

lection of his military writings was published in Vienna.

CHARLES (KARL THEODOR MAXIMILIAN AUGUST), prince of Bavaria and grand prior of the order of Malta, a German soldier, born in Munich, July 7, 1795. He is a son of King Maximilian I. by his first wife Wilhelmine Auguste of Hesse-Darmstadt. He fought against Napoleon at the battle of Hanau (1813), became a general of division, and took part in the campaign of 1814. His differences with Prince Wrede led to his retirement from 1822 till some time after the latter's death in 1838, when his brother King Louis I. appointed him field marshal and general inspector of the army. In the Austro-Prussian war of 1866 he was commander-in-chief of the 7th and 8th corps of the Bavarian army, which cooperated with the Austrian, after which he retired from the public service.

CHARLES I., prince of Roumania, born in Prussia, April 20, 1839. He is a son of Prince Anthony of Hohenzollern, and a brother of Prince Leopold, who was proposed for the Spanish throne in 1870, and belongs to a junior and mediatized branch of the Prussian royal family. He was educated in Dresden, entered the Prussian army in 1857, and served during the Schleswig-Holstein campaign in 1864. After Couza's downfall in 1866, and the refusal of the count of Flanders, brother of Leopold II. of Belgium, to become the ruler of Roumania, Prince Charles was elected in April to that position, with hereditary rights, by a *plébiscite* of the Roumanian people. He reached Bucharest on May 20, in disguise, in order to avoid complications with Austria, which, on the eve of war with Prussia, had protested against the elevation of a Prussian to the sovereignty of the Danubian principalities. He assumed the government on May 22, and was formally recognized on Oct. 24 by the sultan and by the other powers, who had guaranteed the treaties relating to the status of Roumania. Disgusted with the factious spirit of the opposition in the chambers, and insulting anti-Prussian manifestations during the Franco-German war, he declared in 1871 his readiness to resign, but was persuaded to desist from this determination.

CHARLES AUGUSTUS, grand duke of Saxe-Weimar-Eisenach, born Sept. 3, 1757, died June 14, 1828. Having lost his father in the first year of his life, he was very carefully educated together with his posthumous brother, Frederick Ferdinand Constantine, under the regency of his young mother, who in the first year after the death of her husband was herself still under the guardianship of her father. Upon the recommendation of Frederick the Great she appointed as their governor the count of Görtz, afterward Prussian minister, giving them as teachers Seidler and Hermann, Wieland and Knebel, while Schmid conducted the affairs of the little state through the difficulties of the seven years' war. In December, 1774, Charles Augustus together with his brother entered upon a jour-

ney to France and Switzerland, during which he made the acquaintance of Goethe, who became his friend, and afterward his minister. Having been declared reigning duke by his mother on his 18th birthday, he married Louisa, princess of Hesse-Darmstadt, and continued the liberal and reformatory government of his mother, gathering around him at Weimar a circle of distinguished men, among whom were Goethe, Herder, Wieland, and Schiller. In 1786 he took service in the Prussian army, was in the campaigns of 1792-'3 on the Rhine as volunteer, was made Prussian lieutenant general in 1797, and remained in service till after the battle of Jena (1806), when he retired to his dukedom and joined the Rhenish confederacy. His soldiers now fought for Napoleon in Tyrol, Spain, and Russia. Having gone over to the coalition in 1813, he entered the Russian service in the following year, and led an army of Saxons, Hessians, and Russians into the Netherlands. He then went to Paris, London, and Vienna, and took part in the campaign of 1815. The congress of Vienna rewarded him by enlarging his state, and erecting it into a grand duchy, besides granting him a compensation of 800,000 thalers. He was the first of the German princes to introduce the promised constitutional representation (1816), and allowed freedom to the press, until he was induced to adopt restrictive measures by the complications that followed the great gathering at the Wartburg in 1817. He died of apoplexy at Graditz, near Torgau, on his return from Berlin. Several scientific and agricultural institutions, a park, and a botanical garden are among the improvements with which he adorned his country.

CHARLES DE BLOIS, or *de Châtillon*, duke of Brittany, died in 1364. He was the nephew of Philip VI. of France, who, anxious to secure his fortune, married him to Jeanne de Penthièvre, heiress apparent to the ducal crown of Brittany. But on the death of John III., in 1341, the claim of Jeanne was disputed by John of Montfort, brother of the deceased, who asserted that Brittany could not revert to female sovereigns. Thence arose a war of 20 years' duration, in which the kings of England and of France participated, the former giving assistance to Montfort, while the latter supported Charles de Blois. His cause at first promised to be successful; his competitor died about 1345, whereupon Jeanne of Montfort came boldly forward in behalf of her young son, and displayed such courage, inspired her followers with such enthusiasm, and obtained such assistance from the chivalry of England, that fortune at last declared for her. Charles was killed in battle, and the duchy of Brittany was awarded to young Montfort.

CHARLES THE BOLD, duke of Burgundy, son of Philip the Good and Isabella of Portugal, born at Dijon, Nov. 10, 1433, killed in battle near Nancy, Jan. 5, 1477. On the day of his baptism he was created count of Charolais. In infancy

he was taken by his mother to the Netherlands, and at an early age he was confided to the care of the lord of Auxy, who found him a difficult charge. He had a violent temper and obstinate will, but remarkable application, and he acquired more learning than was common among nobles of the time. At the age of 19, in the rebellion of Ghent (1452), he distinguished himself at the battle of Gavre. He was betrothed to a daughter of Charles VII. of France, but she died, and in 1454 he married Isabella of Bourbon, who died in 1465. He was noted for marital fidelity, dislike of luxury, and love for labor and manly sports; but he shared in the pleasures of society, was a graceful dancer, good musician, and the best chess player of his time. In person he was of medium height, with a powerful frame insensible to fatigue, pleasant face, and fine voice, and he was naturally eloquent. In consequence of a quarrel with his father he retired to the Netherlands. In the so-called "war of the public weal" in France (1465) he took an active part, commanding a Burgundian contingent of 10,000 men, and greatly distinguishing himself at Monthéry, where he was wounded. In the subsequent treaty of Conflans he compelled Louis XI. to yield to the demands of the confederates. In 1466 he compelled Liège, which had made war upon Burgundy, to accept his terms of peace, and to pay a large fine, and a subsidy for the expenses of his expedition. In July of that year he marched against Dinant, and completely destroyed it. The death of his father, June 15, 1467, made Charles, at the age of 33, duke of Burgundy. He remodelled the court, and though he lived in great splendor, he required economy and exactness in accounts. Three times a week he held a public audience in which the meanest of his subjects might approach him and be heard. His administration of justice was strictly impartial, without regard to the rank of the offender, and he tolerated no parasites or sycophants. But he was full of extravagant fancies, and his egotism was unbounded. In July, 1468, he married Margaret of York, sister of Edward IV. Immediately afterward the war with Liège was resumed, and in October he marched with 40,000 men against the place and sacked and burned it. This, in connection with his recent triumph over Louis XI. by the conditions of the treaty of Péronne, raised Charles to the highest place among sovereigns. His alliance was sought by all. In the spring of 1469 Sigismund, duke of Austria, hoping to secure him as an ally against the Swiss, conveyed to him for a consideration his possessions in Alsace. Edward IV. conferred on him the order of the garter. Charles wrote and spoke English with facility. It was one of his boasts that he was "more English than the English themselves;" and, Lancastrian by descent, he looked for the possible chance of some time inheriting the English throne. In 1470, when Warwick drove Edward IV. out of England

and forced him to take refuge in Flanders, Charles sent him funds, followers, and a fleet to enable him to return. In February, 1471, with an army of 30,000 men, he began a war with Louis XI. Amiens was besieged for weeks; then followed a truce for three months, with a renewal which was broken by Louis. Thereupon Charles put his army in motion, plundered and burned Nesle in Vermandois, and besieged Beauvais. Here he was unsuccessful, and in three weeks he broke camp for a raid through the plains of Normandy which gave him the title of "the terrible." Not a farm house was left standing; the growing crops were destroyed; a record by Charles's provost marshal states that 2,072 castles and villages were razed or burned. A year's truce followed. This closes the first period of Charles's career, in his failure to undermine the monarchy of France. The second period opens with his efforts to build up beside France a stronger power. The acquisition of Gelderland at the close of 1472 added the fifth duchy to Burgundy. The year following Charles appeared as a military reformer. He had discovered the defects of feudal forces, and began to organize a standing army. Louis had succeeded in forming a league against him, combining France, Austria, the Swiss cantons, and some of the Alsatian free towns. The result was the loss of Alsace; but whether this was owing to a popular insurrection, or, as Charles claimed, to the "conspiracy," is doubtful. The Swiss, who promised to protect Alsace, declared war against Burgundy, and in 1475 the French army invaded the territory, and Charles found himself in the centre of gathering foes. Meanwhile, months before, he had drawn up his army before Neuss; but at the end of the eleventh month he raised the siege, broke camp, and retired without a single conquest. This was in June; in July Edward of England invaded France, and Charles hastened to Calais to join him. He proposed, however, to prosecute the war in concert, but not in company, with his ally; and while Edward should be engaged elsewhere, he would sweep the French out of Lorraine. But in a few days Edward concluded a peace with Louis, which excited the contempt and anger of Charles, and induced a final separation between him and Edward. Compensation came a few months later with the surrender, Nov. 29, 1475, of Nancy to Charles, completing the conquest of Lorraine. He now began an expedition which he expected would be a final blow to all his enemies. Before entering upon his Swiss campaign, he ratified, Jan. 22, 1476, a treaty giving his only child Mary to Maximilian, son of the German emperor Frederick, thus uniting the houses of Burgundy and Hapsburg. In February Charles crossed the Jura and attacked Granson. The garrison soon surrendered, and every one of the 412 prisoners was immediately hanged. Meanwhile the Swiss cantons had been gathering. Charles, to his surprise, was attacked in his fortified camp; the

Burgundian army was put to flight (March 3); as Charles said, "Twenty thousand men turned their backs on ten thousand without drawing a sword," and the slaughter of the fugitives was frightful. But the victorious Swiss soon returned from the pursuit to plunder the camp. The spoils were enormous. Charles, with the intention of holding his court in Savoy, and dazzling the Italian powers by its splendor, had brought with him the state jewels, paraphernalia, and regalia, all of which fell into the hands of the Swiss. These spoils included three great diamonds, one of which is now in the papal tiara, another in the treasury of Vienna, and the third is believed to be the celebrated Sanci diamond owned by Prince Demidoff. The Swiss churches and arsenals still exhibit Burgundian tapestries, banners, cannon, and suits of armor as trophies of the field of Granson. The remnants of the Burgundian army gathered in camp at Lausanne, where, after long prostration by illness, Charles organized another army, with which he invested Morat. The confederates gave him battle, June 22, and completely annihilated his army. Charles's loss has been estimated at from 22,000 to 26,000 men, but by this battle he lost also Lorraine. He was now alone; his allies shrank from him, and he was looked upon as a doomed man. The pope, the emperor of Germany, and Matthias Corvinus of Hungary made a combined effort to save him by offers of mediation with the confederates; but the unconquerable pride of Charles made their efforts fruitless. He gathered an army of 20,000 men, and in September commenced a prolonged siege of Nancy, during which his army dwindled to 10,000. He was urged to withdraw from Lorraine, but stubbornly refused. He would not await an attack in his camp, but on the night of Saturday, Jan. 4, 1477, he silently marched his forces to a position half a league southeast of Nancy. On Sunday morning, after mass, the troops of René, duke of Lorraine, marched out against the Burgundians. The battle was brief. Charles fought with desperation, but was soon struck down by a Swiss halberd. In an hour the Burgundian army was destroyed. On Monday the stripped and mutilated body of the duke was found in a ditch, and was brought to Nancy, where it lay in state for five days in front of the high altar in the church of St. George, and on the following Sunday it was buried. In September, 1550, it was removed to Bruges and laid beside the remains of his daughter in the church of Notre Dame. A simple stone cross still marks the spot where the body of Charles the Bold, the last duke of Burgundy, was found in the field of Nancy.—See "History of Charles the Bold, Duke of Burgundy," by John Foster Kirk (3 vols. 8vo, Philadelphia, 1864-'8).

CHARLES EDWARD (LOUIS PHILIP CASIMIR), an English prince, called the young pretender, son of James Stuart and Clementina Sobieska,

and grandson of James II., born in Rome, Dec. 31, 1720, died there, Jan. 30, 1788. The Jacobite party saw in his birth ground for new hopes. The incapacity of the pretender, or chevalier de St. George, as exhibited in 1715-'16, and the failure of Alberoni's plan for his restoration in 1719, had well nigh driven them to despair. The birth of Charles Edward, and the high character of the race to which his mother belonged, caused a reaction in their feelings, and prolonged the struggle between the constitutionalists and the divine-right party for another generation, which was marked by desperate intrigue, and was concluded in wholesale slaughter. Charles early gave indications of talent, and of a firmness of purpose inherited from his mother, which misfortune caused to degenerate into sheer obstinacy. He was well educated by Protestant tutors, acquiring accurate knowledge of English, French, and Italian, and of the history of England. His physical education was attended to, and he was dexterous in all manly exercises. He had some taste for the fine arts and skill in music. In his 14th year he made his first campaign, serving in the Spanish army that besieged Gaeta, in the war between Spain and Austria. Though so young, he bore himself bravely. In 1737 he made the tour of Italy, and, to the annoyance of the British government, was everywhere well received. At Venice the honors due to a crowned head were accorded to him, for which the Venetian ambassador was dismissed from England. His character at this time was that of an amiable, accomplished youth, and his sweetness of disposition is frequently mentioned. From a very early period his mind dwelt upon the thought of recovering the British throne, and England and France becoming involved in the war of the Austrian succession, Charles was invited to France in 1744 to take command of an army that was to be sent to England. He went to Paris, but Louis XV. would not see him. He made a favorable impression on all persons with whom he came in contact, and particularly upon Marshal Saxe, who was to have been the real head of the invading army. That army was assembled on the channel coast, and consisted of 15,000 men. The transports were to be convoyed by 20 ships of the line and 5 frigates. The English were greatly alarmed. Their channel fleet was small, most of their ships being in the Mediterranean, where they had been sent to the assistance of the house of Austria. The prince and the marshal embarked at the close of February. This was the most favorable turn that the fortunes of the Stuarts ever took after the flight of James II. There was much discontent in England, they had a powerful party in Scotland, and the Irish Catholics looked upon them as promised deliverers. Marshal Saxe was the ablest of living soldiers, and Charles was enthusiastic and resolute. But on March 6 a great storm arose and raged for a week. Many vessels

filled with troops were lost, and the rest were forced back to France. Though Charles earnestly pressed the French government to renew the attempt, he failed; whereupon he directed his attention to private efforts, and with difficulty was prevented from sailing to Scotland in a fishing boat. In 1745, having obtained some assistance from individuals of British origin in France, he fitted out two vessels, the *Elizabeth* of 67 guns, and the *Doutelle* of 16, and placing a quantity of arms and ammunition on board of them, sailed for Scotland, accompanied by a few friends. Of money he had less than £4,000. The *Elizabeth* was brought to action by a British cruiser, and was compelled to fly. This was a serious loss, as most of the stores were in her. The *Doutelle* escaped, and after some adventures Charles landed at Moidart, July 28, where he was joined by a few persons, whose numbers were soon increased, the most prominent of the highland chiefs being Donald Cameron the younger of Lochiel. The Stuart standard was raised at Glenfinnan a few days after. His army now rapidly increased, many clans rising in his behalf. He baffled Sir John Cope, the royal general, descended upon the lowlands, entered Perth, and took possession of Edinburgh, Sept. 17. The lowlanders who joined him were not numerous. The victory of Prestonpans, won Sept. 22, in which Cope's army was annihilated by the highlanders in five minutes, raised the prestige of Charles's arms, and he was enabled to march into England at the head of 6,000 men, entering that country Nov. 8. He took Carlisle, and penetrated to Swarkstone Bridge, 6 m. beyond Derby, and 94 from London, without encountering any opposition, his superior military genius enabling him to baffle the English army under Wade. But if he met no opposition, neither was his force increased, save by a few individuals, most of whom were of the lowest rank. The English nobility at that time contained many Jacobites, and they were still more numerous among the gentry; yet they remained quiet. Discouraged by this coldness, the chiefs compelled Charles to return to Scotland, where a new army had been formed, partly composed of troops from France, and partly of native levies. Charles was bitterly opposed to this course, and the view he took showed his superiority. Had the army pressed forward, London would have fallen into its hands. On the retreat, the insurgents evinced their usual military preëminence, outmarching even their mounted enemies, and inflicting a bloody repulse upon them at Clifton. They took Glasgow after their return, and defeated the English army, commanded by Hawley, Jan. 17, at Falkirk. The duke of Cumberland was then sent to Scotland, and Charles was compelled to retreat again, much against his will. Toward the middle of April, 1746, the two armies were near to one another, and Charles planned a night attack on Cumberland, which failed because of want of due informa-

tion respecting the country. On April 16 was fought the battle of Culloden, which was as fatal to the prince's character for generalship as to the fortunes of his house. With a fatigued, starved, and diminished army he awaited the attack of the superior royal forces, the latter being well supplied with everything necessary to render them efficient. At first the action was one of artillery only, in which the highlanders suffered terribly. At length their right wing charged, swept away a large portion of the first English line, and was itself almost annihilated by the fire and bayonets of the second line. Even then the royal army would have been defeated had the Macdonalds imitated the daring bravery of the MacLeans, Frasers, MacIntoshes, Stuarts, and Camerons; but, angry because they had been placed on the left, whereas they claimed the right as theirs from the day of Bannockburn, they refused to charge, and gave the enemy victory. Culloden was the last battle fought for the fated line of the Stuarts. Charles fled, and after five months of the most romantic wanderings he escaped to France, where he was well received, the king for the first time personally welcoming him. He was a great favorite at court. Some faint show was made of renewing the attempt to invade England, but Charles refused to promise to cede Ireland to France in the event of success, and the plan fell through. He visited Madrid in 1747, and was well received. In 1748 he was expelled from France in compliance with the terms of the peace of Aix-la-Chapelle. This treatment he had brought upon himself, for the French government had sought in every way to avoid extremities, and nothing but the prince's obstinacy made violence necessary. He was also compelled to leave Avignon, and refused a home in Venice. He visited Germany, and afterward resided for some time in the duchy of Bouillon. He became a Protestant in or about 1752. He was engaged in some Jacobite conspiracies, and visited London in 1750 and in 1753. The story that he was present at the coronation of George III. is slenderly supported. He finally took up his residence in Florence. His father dying at the close of 1765, he became the legitimate king of Great Britain. This title he never assumed, but was known as the count of Albany, which designation he had borne as early as 1734. He married in 1772 the princess Louisa of Stolberg-Gedern, who was more than 30 years his junior. The only effect of this marriage was to add domestic misery to the sufferings of the prince. Alfieri was the princess's lover. She fled from her husband, and a judicial separation took place in 1783. His last years were spent at Rome, where he died on the anniversary of the execution of his great-grandfather, though most accounts place the event on the following day. He left an illegitimate daughter, who survived him but a year. He was one of those rare characters who bear prosperity better than adver-

sity. His talents were high, and no member of the Stuart family ever exhibited more practical ability. His conduct in the campaign of 1745-'6 evinced an original genius for war. He found himself in circumstances entirely new, and he adapted himself to them with all the facility of genius.—The history of Charles, and of his Scottish campaign, has been written by Walter Scott, Robert Chambers, Pichot, J. H. Jesse, Earl Stanhope, C. L. Klose, and others. There is much curious matter respecting the conduct of the Jacobites, and of the prince and his family, in the "Memoirs of Sir R. Strange, and of Andrew Lumisden," by Mr. Dennistoun, Mr. Lumisden having been private secretary to both Charles and his father. In the early years of the 19th century the interest in the history of "the young pretender" was renewed by the writings of Scott, who introduced him into two of his novels, "Waverley" and "Redgauntlet."

CHARLES, Jacques Alexandre César, a French physicist, born at Beaugency, Nov. 12, 1746, died in Paris, April 7, 1823. He was remarkable for his skill in public experiments and demonstrations; and his lecture room, in which he popularized the electrical discovery of Franklin, was attended by one of the most brilliant assemblies of Paris. Montgolfier having sent up a balloon filled with rarefied air, Charles immediately constructed the first balloon ever made capable of holding hydrogen gas, with which an aeronaut successfully ascended, Aug. 2, 1783. Charles afterward made an aërostatic voyage himself, rising to the height of 7,000 ft. He invented the megascope and other ingenious optical instruments, was a member of the academy of sciences and librarian of the institute, and had one of the most beautiful cabinets in Europe.

CHARLES CITY, a S. E. county of Virginia, bounded S. by James river, N. and E. by the Chickahominy; area, 184 sq. m.; pop. in 1870, 4,975, of whom 3,153 were colored. It was one of the eight original shires into which Virginia was divided in 1634. The chief productions in 1870 were 55,269 bushels of wheat, 111,244 of Indian corn, and 47,578 of oats. There were 355 horses, 880 milch cows, 926 other cattle, and 3,903 swine. Capital, Charles City Court House.

CHARLES MIX, a S. E. county of Dakota, having the Missouri river on its S. W. border; pop. in 1870, 152, of whom 117 were civilized Indians. The chief productions in 1870 were 8,810 bushels of Indian corn, and 1,315 of potatoes. The value of live stock was \$22,250. Capital, Greenwood.

CHARLES RIVER, a stream rising in Worcester co., Mass., and flowing through Norfolk and Middlesex counties into Boston harbor. The towns on its banks are Hopkinton, Milford, Bellingham, Franklin, Medway, Medfield, Sherburne, Dover, Dedham, Needham, Natick, Newton, Waltham, Watertown, Brighton, and

Cambridge. It affords numerous sites for mills and factories, and is navigable to Watertown, 7 m. W. of Boston. The lower part of its course is the favorite training place of the boat clubs of Harvard university. It is now (1873) proposed to draw from the upper part of this river an additional supply of water for Boston.

CHARLES'S WAIN, a name given to the constellation Ursa Major, or the Great Bear, often called also the Dipper. The literal meaning of the name is the rustic's wagon, and some fancied resemblance doubtless was the occasion of its use.

CHARLESTON, a county of South Carolina, bordering on the Atlantic, including several islands, of which the largest is Edisto; area, 1,906 sq. m.; pop. in 1870, 88,863, of whom 60,603 were colored. The Santee river bounds it on the north, and it is drained by Ashley and Cooper rivers, which unite to form the harbor of Charleston. The other chief river is the Edisto, and there are numerous inlets, including, besides Charleston harbor, the N. and S. Edisto and S. Santee, which are generally navigable by small craft. The coast is broken by several bays and protected by a stretch of sandy islands. The surface is low, level, and in some places exposed to inundation. The soil embraces every variety, from the richest alluvial mould to the most sterile sand. There are large quantities of waste land, most of it reclaimable. The famous sea island cotton is raised along the rivers and coast. Formerly indigo, tobacco, silk, and wine were extensively produced. The olive, orange, and lemon have been found to mature in the open air, though cut down by occasional severe winters. The palmetto and the pine are among the indigenous forest trees. The South Carolina railroad, which terminates at Charleston city, runs through this county, and also the Savannah and Charleston and the Northeastern railroads. A communication between the Santee and Cooper rivers has been opened by a canal 22 m. long. The chief productions in 1870 were 170,087 bushels of Indian corn, 24,110 of peas and beans, 62,984 of sweet potatoes, 5,512 bales of cotton, and 4,329,217 lbs. of rice. There were 1,044 horses, 1,220 mules and asses, 2,565 milch cows, 4,321 other cattle, 2,869 sheep, and 10,390 swine. Capital, Charleston.

CHARLESTON, a city, the capital of West Virginia and of Kanawha county, on the Kanawha river, 60 m. from its mouth and at its confluence with Elk river, 233 m. W. by N. of Richmond, and 130 m. S. by W. of Wheeling; pop. in 1870, 3,162, of whom 761 were colored. The Kanawha is 300 yards wide here, and is navigable throughout the year. The valley of this river is rich in salt, coal, iron, and timber, and Charleston is a central point for the working and shipping of these articles. In the vicinity of the city are 10 salt furnaces; more salt is made here annually than at any other point in the country except Syracuse, N. Y.

They are situated in the Kanawha Salines, beginning about 2 m. above Charleston, and extending up the river on both sides for 10 m. A great variety of coal is found in abundance, such as cannel, splint, and all kinds of bituminous coals. Locks and dams are in process of construction on Elk river in order to facilitate the transportation of the immense quantities of coal and timber that abound along its banks for over 100 m. The Chesapeake and Ohio railroad, which is designed to be one of the great through routes between the east and west, passes through Charleston. The Northern and Southern West Virginia railroad, in progress, terminates here. The state house is a capacious stone building, 138 ft. long, 56 wide, and 140 high, erected in 1870 at a cost, including land, of about \$60,000. The other state institutions are in other parts of the state. The manufacturing establishments comprise 2 iron founderies with machine works attached to each, 4 saw and planing mills, a cabinet factory, 2 factories for making staves and headings for salt and flour barrels, a pump factory, a mineral water factory, 2 large flour mills, and a woollen factory. There are a high school called the Charleston institute, a public school, a Roman Catholic seminary, and several private schools. There are 8 churches, 4 weekly newspapers, and a monthly periodical. The seat of government was removed from Wheeling to Charleston by an act of the legislature of 1869, which went into effect April 30, 1870.

CHARLESTON, the chief commercial city of South Carolina, a port of entry, and capital of Charleston co., in lat. $32^{\circ} 45' N.$, lon. $79^{\circ} 57' W.$, 100 m. S. S. E. of Columbia, the capital of the state, 82 m. N. E. of Savannah, Ga., and 455 m. S. S. W. of Washington, D. C. It stands at the confluence of the Ashley and Cooper rivers, which here unite and form a spacious harbor. These rivers run a parallel course for nearly 6 m., widening as they approach the sea, thus gradually narrowing the site of the city into a peninsula. The city is built upon low and level land, and to one approaching by water seems to rise from the sea. The harbor is a large estuary extending about 7 m. S. E. to the Atlantic, with an average width of 2 m. It is landlocked on all sides except an entrance of about a mile in width. S. of this entrance, extending along the coast, is Morris island, about 5 m. long and 3 m. wide. The width of the inner harbor at its mouth is something over a mile. The passage is defended by four fortresses. On the right hand, at the entrance, is Fort Moultrie, on Sullivan's island, occupying the site of the fort which, on June 28, 1776, beat off the British fleet of Sir Peter Parker. On the left hand, raised upon a shoal in the harbor, and directly covering the channel, is Fort Sumter. Immediately in front of the city, and but a mile from it, is Castle Pinckney, covering the crest of a mud shoal, and facing the entrance. A little S. of Pinck-

ney is Fort Ripley, a small square work, built in 1862. On the S. side of the harbor, about $1\frac{1}{2}$ m. from the city, are the ruins of Fort Johnson. The outer harbor, lying within the bar, extends from Sullivan's island to the south channel, below the lighthouse, a distance of 6 m. The bar consists of successive ranges of sand banks, which stretch away before the entrance for several leagues; and as these ranges consist in part of quicksand, they are liable, from storms and undercurrents, to occasional change of locality, greatly increasing the difficulty of pilotage. Between these successive ranges of sand are formed several channels of varying depths of water. There are four of these channels: the ship channel, with 16 ft. water at ebb; the small or middle channel, with 14 ft.; Lawford's, or the south channel, with 10 ft.; and Maffit's, close to the shores of Sullivan's island. The ship channel is $11\frac{1}{2}$ m. from the city, the middle $7\frac{1}{2}$, while that of Maffit is still nearer. The approach to the coast is easy, the shoaling gradual, and with proper care and good seamanship the soundings alone would assure the mariner of safety. The lights along the coast of this district begin at Cape Roman; there is a light at Bull's, and floating lights and bell boats contribute to disarm all the dangers of the coast. The lighthouse at the entrance of Charleston harbor is on Lighthouse island, and W. of the ship channel, lat. $32^{\circ} 41' 55'' N.$, lon. $79^{\circ} 52' 29'' W.$ The tower is of brick, 110 ft. high; the light is at an elevation of 133 ft. above the sea. It may be seen at a distance, in good weather, of 20 nautical miles. The beacon in front of the main light is visible at a distance of 10 nautical miles. The height of the light above the sea level is 50 ft. There are beacons also on Morris and Sullivan's islands, at Fort Sumter, Castle Pinckney, Mount Pleasant, and on the battery at White point, all within the harbor. From the entrance of the middle channel a full view of the city is obtained, guided by the spire of St. Michael's church, which bears from this point about N. $63^{\circ} W.$ The surrounding country is noted for the picturesque character of its scenery. Rice and cotton fields, oaks, magnolias, myrtles, and jasmynes abound in profusion. On Sullivan's island are many cottages owned by the wealthy citizens of Charleston and vicinity, and occupied by them during the summer. The mean annual temperature at Charleston in 1872 was 65.5° ; total rainfall, 58.83 inches; prevailing wind, southwest. The mean temperature in January was 45° , February 48.5° , March 51° , April 65.6° , May 74.9° , June 79.7° , July 84.1° , August 81.8° , September 77.8° , October 69° , November 59° , December 49° .—The population in 1800 was 18,711; 1810, 24,711; 1820, 24,780; 1830, 30,289; 1840, 29,261; 1850, 42,985; 1860, 40,519, of whom 17,146 were colored; 1870, 48,956, of whom 22,749 were colored. Only 4,892 of the total population in 1871 were foreigners. There were 6,861 dwellings, with an average of 7.14 persons

Charleston, from the Bay.

to each, and 9,098 families, with an average of 5.38 persons to each. There were 18,705 persons engaged in mechanical occupations, 9,949 in professional and personal services, 4,929 in manufactures and mining, 3,496 in trade and transportation, and 331 in agriculture. The corporate limits of Charleston extend from Battery or White point, on the extreme southern verge of the city, to an arbitrary line on the north, fully three miles above. The city covers a large extent of territory. The dwellings are generally isolated, having large open grounds on every side. The city is laid out with tolerable regularity. The streets, with few exceptions, cross at right angles. The two principal, King and Meeting, run N. and S., nearly parallel, the whole length of the city, but converge to intersection near the northern limits. The cross streets extend from E. to W., from Cooper to Ashley river, and are generally narrow. The principal streets are well paved and lighted with gas. The houses are mostly of brick or wood. There are few regular blocks or rows of buildings, and no uniformity; but what is lost in this respect is gained in variety, and, with fine gardens, open plats of shrubbery, shade and fruit trees, creepers, vines, the magnolia, the oak, the cedar, and the pride of India, girdling the white dwellings and the green verandahs, the effect is highly picturesque. There are few public squares, and these are generally small. The Battery is a popular promenade, lying near the water's edge and commanding an extensive view of the bay; it is surrounded by fine private residences. The principal public buildings are the orphan house, with its spacious grounds; the new custom house, which has been in process of construction for several years; the city hall, corner of Broad and Meeting streets; and the medical college and Roper hospital, in Queen street. The academy of music, corner of King and Market streets, which was converted to its present use in 1869, is one of the finest theatres in the south. It has a front of 60 ft., is 231 ft. deep, 75 ft. high, and cost \$160,000. Besides

the theatre, with accommodations for 1,200 persons, it has two large halls for concerts, lectures, and public meetings. St. Michael's church is a noted edifice, built in 1752. A fine view of the sea and the shores may be obtained from the tower, which contains a chime of bells, and can be seen far out at sea. St. Philip's church (Episcopal), in Church street, is the oldest church establishment in Charleston, but the present edifice is not quite so old as that of St. Michael's. Interred in the adjoining graveyard are the bodies of many noted persons, including Gadsden, Rutledge, and Pinckney. Here also is the tomb of John C. Calhoun, consisting of a plain granite slab supported by walls of brick and bearing the inscription "Calhoun." Just outside of the city, on the N. boundary, is the Magnolia cemetery, in which there are some fine monuments. The railroads centring in Charleston are the Savannah and Charleston, the Northeastern, extending from Charleston to Florence, and the South Carolina, extending to Augusta, Ga. There is a tri-weekly line of eight steamers running to New York, and there are two steamers each to Baltimore, Philadelphia, and Boston. There are also steamers to Savannah and Florida, and to various points on the South Carolina coast. The different parts of the city are connected by lines of street cars and omnibuses. —Charleston is the nearest of the important southern ports to the northern cities, and is the first harbor having ample room and good anchorage reached by southward-bound vessels on the long stretch from the Chesapeake. It is the principal shipping port of the state and adjacent country. For the year ending June 30, 1871, the value of imports from foreign countries was \$621,559; exports to foreign ports, \$12,387,524. Included in the exports were 5,084 bales of sea island cotton, valued at \$829,892, and 172,643 of upland cotton, valued at \$11,195,972. There entered from foreign countries 51 American vessels, 12,039 tons, and 106 foreign vessels, 36,065 tons; cleared for foreign ports, 64 American vessels, 25,813 tons,

and 120 foreign vessels, 48,726 tons; entered in the coastwise trade, 485 vessels, 347,731 tons; cleared, 430 vessels, 318,801 tons; registered, enrolled, and licensed, 160 vessels, 8,270 tons, of which 19 with a tonnage of 3,548 were steamers. During the year there were built 12 vessels of 308 tons. The total exports for the year ending Aug. 31, 1872, were valued at \$10,927,986, and the imports at \$734,471. The total number of merchant vessels belonging to the port was 152, of 6,006 tons. The most important article of export is cotton. In the extent of this trade Charleston ranks next to New York and New Orleans. Its amount for a series of years ending Aug. 31 is shown in the following statement:

YEARS.	Sea Island, bales.	Upland, bales.	Total, bales.
1866.....	5,630	102,521	108,151
1867.....	16,441	133,418	169,859
1868.....	9,352	235,713	245,065
1869.....	7,340	195,280	202,570
1870.....	12,848	236,653	349,501
1871.....	11,684	342,811	354,495
1872.....	11,789	270,565	282,154

Between a third and a half of the total exports are shipped to foreign ports, chiefly those of England and France, and the remainder to northern ports of the United States. Rice also enters largely into the commerce of the city, the exports in 1872 amounting to 42,574 tierces; 1871, 43,917; 1870, 38,688; 1869, 35,609; 1867, 22,333. In 1872, 18,460,339 ft. of lumber were shipped, 15,728,467 in 1871, 13,205,066 in 1870, and 18,558,652 in 1869. Naval stores form a leading article of commerce, the exports in 1872 amounting to 147,910 barrels. The wholesale trade of Charleston has greatly increased since the war. In 1872 the sales of dry goods amounted to \$3,000,000; boots and shoes, \$1,200,000; clothing, \$400,000; drugs and medicines, \$375,000; hats and caps, \$175,000. In 1873 Charleston had 3 national banks and 4 state banks, with an aggregate paid-up capital of \$2,930,000, and current deposits amounting to \$1,590,000; and 4 savings banks, with deposits to the amount of \$1,155,990. The manufacture of fertilizers from the valuable beds of marl and phosphate rocks in the vicinity has since 1868 been developed into one of the most important industries in the city. In 1873 there were 6 factories in and near the city, employing a capital of \$400,000. The shipments of fertilizers have advanced from 3 tons in 1867 to 27,355 tons in 1871, and 30,646 tons in the first six months of 1872. In connection with this business the manufacture of sulphuric acid is extensively carried on. Five of the establishments mentioned above have acid chambers, and from 1869 to July 1, 1872, manufactured 10,614 tons of sulphuric acid, valued at \$350,200. The exports of crude phosphate rock from Charleston and Beaufort from Jan. 1, 1867, to July 1, 1872, amounted to 206,305 tons, valued at \$1,450,000; of this amount 90,225 tons were shipped to foreign

and 116,080 tons to domestic ports. The amount consumed by local companies during this period was 36,110 tons, valued at \$250,000. According to the census of 1870, the total number of manufacturing establishments in Charleston county, which were chiefly in the city, was 224, using 54 steam engines of 1,140 horse power, and employing 2,579 hands. The capital invested amounted to \$1,538,539; wages paid during the year, \$616,962; value of materials consumed, \$1,264,731; of products, \$2,431,763. The chief establishments were 13 bakeries, 13 manufactories of carriages and wagons, 2 of fertilizers, 8 of flour, 15 of sawed lumber, 7 of machinery, 13 of tar and turpentine, and 7 establishments for ship building and repairing. Among the most important industrial establishments in Charleston are the capacious mills for removing the husk from rice and preparing the grain for market. A large proportion of the rice crop of South Carolina and Georgia is cleaned at these mills, which turn out about 30,000 tierces per annum. There are 3 of these mills, employing a capital of about \$500,000.—The city is divided into 8 wards. The government is vested in a mayor and 18 aldermen. The fire department comprises 14 engine companies, 6 having steam fire engines, and one hook and ladder company. Among the charitable institutions are an almshouse, dispensaries, the orphan house for both sexes, which usually has about 200 inmates, Shaw's orphan asylum, and the Roper hospital. The schools of the city are under the control of 8 commissioners elected by the people and a superintendent chosen by the commissioners. In 1872 the number of children of school age was 12,727, of whom 5,068 were enrolled in the public schools. There were 8 public schools (5 grammar and 3 primary), with 64 male and 4 female teachers, and 2,620 pupils in attendance, and a high school with 65 pupils. The total school expenditures amounted to \$40,453, of which \$36,813 was for teachers' wages. There are also several private schools and a school connected with the Catholic convent. Charleston college, founded in 1787, in 1872 had 5 instructors, 50 students, and a library of 8,000 volumes. The medical college of the state of South Carolina had 9 professors. The Charleston library society, founded in 1748, has 14,000 volumes, and the apprentices' library is a valuable collection. There are 3 daily, 2 tri-weekly, 2 semi-weekly, and 6 weekly newspapers, and 3 monthly periodicals. The city has a literary and a scientific society, and several social organizations. The chamber of commerce and the board of trade are influential bodies. There are 14 lodges and 6 chapters of freemasons, and 6 lodges and 5 encampments of odd fellows. The total number of churches is 39, embracing the following denominations: 10 Episcopal, of which 2 are for colored persons; 7 Methodist, of which 4 are colored; 7 Roman Catholic; 6 Presbyterian, including 1 colored; 4 Baptist, of which

2 are colored; 3 Lutheran, 1 Unitarian, and 1 Huguenot.—Charleston was originally settled about 1679, by an English colony under William Sayle, who became the first governor. He first attempted a settlement at Beaufort, but abandoned this place in consequence of its insecurity. It was too easily accessible by sea, and too difficult of defence in a period when England had several maritime competitors. Sayle transplanted his colony next to the W. side of Ashley river. After his death another removal took place, and the colonists passed over E. of the river, and planted themselves on the W. bank of the Cooper; and Oyster Point became Charleston. Its history from that period to the close of the revolution, nearly 100 years, is one of curious and remarkable interest. Charleston was one of the first among the chief places of the south to assert a common cause with and for the colonies. It was the first to assert its own independence, and to make a constitution for itself. It was thrice attempted by the enemy: first in the assault by Sir Peter Parker and Gen. Clinton on the palmetto fort (since Fort Moultrie) at Sullivan's island, in 1776, when the British fleet and army were beaten off, and almost destroyed; next by the attempted *coup de main* of Gen. Prevost, in 1779; and thirdly, in the regular investment of the city by Sir Henry Clinton, when it stood a siege of six weeks by 12,000 British regulars, and succumbed at last to overwhelming force, May 12, 1780. The city was evacuated by the British Dec. 14, 1782. Charleston was the leading city both in the nullification movement (see SOUTH CAROLINA) and in the incipient stage of southern secession. Open hostilities in the civil war began at Charleston with the bombardment of Fort Sumter by the confederates on April 12, 1861. (See FORT SUMTER.) From this time until the spring of 1865 the city remained in possession of the confederates. Early in the spring of 1863 preparations were made for a naval attack upon the fortifications in Charleston harbor; and on April 6 the federal fleet of 9 iron-clads, carrying 30 guns, commanded by Admiral Du Pont, crossed the bar and entered the harbor. The fortifications in the harbor were formidable, consisting of the forts and numerous batteries well mounted with heavy guns. Moreover, the channel between Fort Sumter and Sullivan's island was obstructed by a tight hawser buoyed up by floating casks, to which were attached torpedoes and other submarine obstacles, while impassable rows of piles had been driven in the channel between Fort Sumter and Cummings point. The attack was made on the 7th, when the gunboats were subjected to such a terrific fire from all the forts that they were soon compelled to withdraw. Morris island and the entrance to Charleston harbor having been subsequently occupied by the Union forces under Gen. Gillmore, occasional shots were directed against Charleston. Upon the surrender of Columbia, the state capital, to Gen. Sherman on Feb. 17, 1865,

Charleston was evacuated by the confederate forces, all the public buildings, stores, cotton warehouses, shipping, &c., having been fired by order of Gen. Hardee, who was in command of the city. On the 18th Charleston was occupied by the federal troops, who exerted themselves to extinguish the flames. During the war many buildings were destroyed, and the towers and steeples of churches riddled with shot and shell. Business and trade were paralyzed. Since its close rapid progress has been made in the work of rebuilding, and in every department of trade and industry. In 1872, \$473,800 was spent for new buildings and repairs in the city, besides \$177,509 for similar purposes on Sullivan's island.

CHARLESTOWN (Indian, *Mishawun*), a city of Middlesex co., Massachusetts, one of the oldest places in the state, separated from Boston on the south by Charles river. It occupies a peninsula formed by the Charles and Mystic, connecting on the northwest with the mainland at Somerville by a very narrow isthmus. Originally the territory was large, but Woburn, Stoneham, Burlington, Somerville, Malden, much of Medford, and portions of Cambridge, Arlington, and Reading have been taken from it, leaving Charlestown in extent the smallest town in the state. It is connected with Boston by the Charles river and Warren bridges, completed in 1786 and 1828 respectively, so that the two places form but one community for most social and business purposes. It is also connected with Chelsea by the Chelsea bridge, with East Cambridge by the Prison Point bridge, and with Malden by the Malden bridge. Horse cars run to Boston and the adjoining towns, and the Eastern, Fitchburg, and Boston and Maine railroads pass through the city. Since the beginning of this century the population has exhibited a steady growth. In 1800 it was 2,751; 1810, 4,959; 1820, 6,591; 1830, 8,783; 1840, 11,484; 1850, 17,216; 1860, 25,065; 1870, 28,323. Of the population in 1870, 6,924 were foreigners. The peninsula is about $1\frac{1}{4}$ m. long. The surface is very uneven, and near the centre rises into two eminences, known as Bunker and Breed's hills. The streets are generally spacious and finely shaded. The most noteworthy are Main, Bunker Hill, and Medford streets, which, starting at the S. extremity, extend the whole length of the peninsula, and joining at the neck form a broad avenue, which passes on into Somerville. These, in the upper part of the peninsula, are crossed with considerable regularity by other streets passing from the Mystic to the Charles, while the S. portion is more irregularly laid out. The city is for the most part handsomely built. Charlestown is chiefly known as the seat of the Massachusetts state prison, of a United States navy yard, and of Bunker Hill monument. The state prison is upon a low point of land, known as Prison point, at the W. extremity of the city. The walls are washed on the west and north by tide water. It was built in 1805,

but has since been much improved and enlarged, and contains 650 cells, with 14 solitary ones for punishment, a chapel, hospital, school room, workshops, storehouses, &c. This institution, which is one of the best of its kind in the country, is conducted on the congregate system, the convicts working together in shops during the day, but being separated at night. The labor is let to contractors, the prisoners being employed in shoemaking, blacksmithing, bronzing, in the manufacture of brushes, chains, iron bedsteads, spring beds, and in foundry work. There is a library of over 3,000 volumes, a Sunday school with an average attendance of over 100, and an evening school attended by 140 prisoners. The whole number of convicts in prison during the year ending Sept. 30, 1872, was 703, of whom 160 were received during the year; discharged, 122; died, 19; in prison at the end of the year, 562, of whom 382 were natives, 180 foreigners,

Hill monument, 221 ft. high, co-spiciously situated on Breed's hill, itself 75 ft. above the sea, commands an extensive view of the surrounding country, and is much resorted to by visitors. (See BUNKER HILL.)—Charlestown forms a part of the Boston customs district, and is a place of considerable business. The principal manufactories are 2 of steam boilers, 3 of cabinet ware, 1 of cameras, 1 of sashes, doors, and blinds, 1 of masts and spars, 1 of pumps and blocks, 1 of shoe bindings, 1 of soap, 1 of soap stone, 1 of tables, 2 of varnish, 1 of wooden ware, 1 bookbindery, 1 brass and copper foundry, 1 brewery, 1 distillery, 4 leather-carrying establishments, 2 grist mills, 1 iron foundry, 9 establishments for dressing and coloring morocco, and 1 tannery. The Charlestown gas company has a capital of \$400,000. There are 2 national banks, with \$650,000 capital; 2 savings banks, with deposits in 1871 amounting to \$4,738,649; and 1

fire insurance company. Charlestown has been connected with the ice trade from an early period, and great numbers of vessels are annually laden with that article at its wharves. The city is divided into 3 wards. The government is vested in a mayor, a board of aldermen consisting of 3 from each ward, and a common council of 6 from each ward. The police department consists of a chief of police, a captain, a lieutenant, 31 policemen, and 14 substitutes and special policemen. The fire department is under the charge of a

Charlestown Navy Yard.

and 40 were colored; 62 were serving out a life sentence. The number of officers was 38. The total expenditure during the year amounted to \$134,560 21; the total receipts reached the sum of \$149,195 44, of which \$126,010 23 were the earnings of convicts; net income of the prison, \$14,635 23. The net income averages about \$20,000 a year. The price obtained for the labor of each convict averages 99 cents a day. The number of convicts in prison Feb. 15, 1873, was 585. The navy yard, established in 1798, is on the N. side of Charles river, at the E. extremity of the city; it is enclosed by a high wall of great strength, and covers about 60 acres. The yard contains several dwelling houses, numerous storehouses, ropewalks, machine shops, ship houses, cannon foundries, &c. The dry dock, which was opened in 1833, is 341 ft. long, 80 broad, 60 deep, and cost \$670,000. Some of the best ships of the national marine have been built at this yard. Bunker

chief engineer, 4 assistants, and a secretary. There are 2 steam engines, 5 hose companies, and a hook and ladder company. The city is supplied with water from Mystic lake in Medford, 5 m. distant. It was first introduced in 1864. Among the charities are the Charlestown poor's fund, founded by Richard Russell in 1674, and now amounting to about \$23,000, the Winchester home for aged and indigent women, and the Devens benevolent society (organized in 1819 under the name of the female benevolent society). Other institutions worthy of mention are the children's home association, the young men's Christian association, and a working men's trading association. The schools are under the charge of a board, consisting of the mayor, a secretary, treasurer, superintendent, and 6 members from each ward. They have under their management a high school, 5 grammar, 38 primary, and 3 intermediate schools, and a select school.

There are 13 male and 101 female teachers; average attendance about 5,000. The Howard grammar school, house, completed in 1872, cost \$92,000. The public library was established in 1860, and contains about 15,000 volumes. There are also four circulating libraries and two weekly newspapers. The city contains 13 churches, viz.: 3 Baptist, 2 Methodist, 2 Roman Catholic, 2 Congregational, 1 Episcopal, 1 Independent, 1 Unitarian, and 1 Universalist.—Charlestown dates from 1628, though Mr. R. Frothingham, the local historian ("History of Charlestown," 1848), thinks that July 4, 1629, is the only date for the foundation of the town for which any good authority can be adduced. It is one of the most interesting spots in American history. A flourishing and noted place in the colonial period, it became conspicuous at the very commencement of the revolution, as well from political as from military circumstances. The British force that fled from Concord and Lexington fell back upon Charlestown, and Gen. Gage threatened to destroy the place if the troops were molested. Most of the inhabitants left their homes, so that on June 17, 1775, when the town was destroyed, not above a tenth part of their number were present. The resolution to fortify Bunker hill, taken by the Massachusetts committee of safety, led to the battle of that name. In the course of this battle, and as one of its incidents, Charlestown was destroyed by a discharge of shells from Copp's hill in Boston, and by men who were landed for the purpose of firing the town. The destruction was complete, with the exception of a few houses. About 400 buildings were burned, and the value of property lost was estimated at over \$500,000. In 1873 a provisional act for the incorporation of Charlestown with Boston on Jan. 1, 1874, was confirmed by the vote of its inhabitants.

CHARLESTOWN, a town of West Virginia, capital of Jefferson co., on the Winchester, Potomac, and Strasburg division of the Baltimore and Ohio railroad, about 10 m. S. W. of Harper's Ferry; pop. in 1870, 1,593, of whom 537 were colored. It is surrounded by a fertile and beautiful country. There are three or four churches, an academy, and a bank. John Brown was tried and executed here Dec. 2, 1859.

CHARLET, Nicolas Toussaint, a French artist, born in Paris in 1792, died there in 1845. His father was a poor soldier, and he received but a scanty education; but while employed in registering recruits for the municipality he laid the foundation for his remarkable knowledge of soldierly characteristics. Being a zealous Bonapartist, he lost his place in 1816. He then studied under Gros, and soon produced his first lithographic work, representing a Waterloo grenadier under the popular title, *La garde meurt, mais ne se rend pas*. Encouraged by its great success, he executed thousands of lithographic prints and drawings in water colors and sepia, with humorous, grotesque,

and graceful representations of the soldier's life, which became exceedingly popular. He struggled with adversity till about 1820, when, after his return from a visit to London with the painter Géricault, he found a more regular and lucrative market for his productions; and in the opinion of his admirers, their patriotic spirit contributed nearly as much as the songs of Béranger in paving the way for the revolution of 1830. In 1831 he was made chevalier and afterward officer of the legion of honor. At the close of 1832 he reproduced the incidents of the siege of the citadel of Antwerp from his observations on the spot. His painting, in 1836, of an "Episode in the Retreat from Russia," in the museum of Lyons, which was regarded by Alfred de Musset as a perfect poem, led the government to commission him in 1837 to paint a picture of the passage of the Rhine at Kehl by Moreau for the Versailles museum; and his "Convoy of Wounded Soldiers halting in a Ravine" is in that of Valenciennes. In 1838 he was appointed professor of design in the polytechnic school, and introduced pen drawing in place of previous methods of instruction. He also continued to produce lithographic works, including 52 renowned illustrations of *La vie civile, politique et militaire du caporal Valentin* (1838-'42), and 500 plates for Bourdin's *Mémorial de Sainte-Hélène* (1841-'2). Despite ill health he was active to the last. D. A. M. Raffet (1804-'60) and J. L. H. Bellangé (1800-'66) were among his ablest pupils. His life-long friend Col. J. F. L. de La Combe published *Charlet, sa vie, ses lettres, suivi d'une description raisonnée de son œuvre lithographique* (Paris, 1856).

CHARLEVILLE (early in the middle ages called *Arca Remorum* and *Carolopolis*), an old town of France, in the department of Ardennes, on the Meuse, about a mile N. of Mézières, with which it is connected by a suspension bridge, and 10 m. N. W. of Sedan; pop. in 1866, 11,244. It was a military station until the end of the 17th century, when its fortifications were destroyed, and subsequently the royal manufactory of arms was removed. The prosperity of the town has since increased. It has an active export trade in wine, spirits, coal, iron, and slates; a manufactory of muskets, nail works, copper founderies, and tanneries; a commodious port, a public library of 25,000 volumes, a college, an ecclesiastical school, normal school, and theatre.

CHARLEVOIX, a N. W. county of Michigan, bordering on Lake Michigan, and intersected by Green river; area, about 500 sq. m.; pop. in 1870, 1,724. Its N. W. shore is deeply indented by Little Traverse bay, and two or three considerable lakes lie wholly or partly within its boundaries. The chief productions in 1870 were 5,527 bushels of wheat, 5,155 of Indian corn, 3,251 of oats, 31,310 of potatoes, and 18,066 lbs. of maple sugar. The value of live stock was \$28,602. Capital, Charlevoix.

CHARLEVOIX, an E. county of Quebec, Canada, bounded N. E. by the river Saguenay, and S. E. by the St. Lawrence; area, 5,224 sq. m.; pop. in 1871, 15,611, all but 341 of French descent, and all but 9 Roman Catholics. It is traversed by the Laurentian mountains, and much of the rest of the surface is rugged, and some of it mountainous. The rivers Gouffre, Malbaie, Menin, Bouchard, and Noire fall into the St. Lawrence; the Petit Saguenay into the Saguenay. Numerous lakes are interspersed over the surface. Capital, Baie St. Paul.

CHARLEVOIX, Pierre François Xavier de, a French historian, critic, and traveller, born at St. Quentin, Oct. 29, 1682, died at La Flèche, Feb. 1, 1761. He entered the society of Jesus in 1698, and while a scholar he was sent to Quebec in 1705 and was employed for four years in teaching in the college at that place. On completing his divinity studies he became professor of belles-lettres in France. After publishing a history of Christianity in Japan he returned to Canada in 1720, to write his history of that province. He remained for a time at Sault St. Louis, where his room is still shown, ascended the St. Lawrence, and reaching the Mississippi by way of the Illinois, descended to New Orleans, returning to France by way of Santo Domingo, after two years' absence. In 1724 he published a life of Mother Mary of the Incarnation, first superior of the Ursulines at Quebec, and from 1733 to 1755 he was one of the directors of the *Journal de Trévoux*. He published in succession a history of Santo Domingo and a history of Japan, and in 1744 his *Histoire de la Nouvelle France*, which had been held back for nearly 20 years. With it appeared his journal while in America, addressed to the duchess de Lesdiguière, which was soon after translated into English and highly esteemed. The history, though praised and cited by historical scholars, remained untranslated till recently, when an edition in English was published at New York by J. G. Shea (6 vols., 1865-'72). His last work was a history of Paraguay (1756).

CHARLOTTE, a S. county of Virginia, bounded S. W. by Staunton river; area, 550 sq. m.; pop. in 1870, 14,513, of whom 9,613 were colored. The surface is hilly. The Atlantic, Mississippi, and Ohio railroad crosses the N. end, and the Richmond, Danville, and Piedmont road traverses the county. The chief productions in 1870 were 75,194 bushels of wheat, 194,260 of Indian corn, 118,931 of oats, and 1,964,736 lbs. of tobacco. There were 1,035 horses, 1,715 milch cows, 2,506 other cattle, 3,223 sheep, and 7,224 swine. Capital, Marysville.

CHARLOTTE, a city of North Carolina, capital of Mecklenburg co., on Sugar creek, 125 m. W. S. W. of Raleigh; pop. in 1870, 4,473, of whom 1,880 were colored. The Charlotte, Columbia, and Augusta, the Wilmington, Charlotte, and Rutherford, and the North Carolina railroads meet here. A plank road 120 m.

long connects it with Fayetteville. The city is situated upon the gold range of the Atlantic states, and its prosperity is principally owing to the working of the mines in its vicinity. A branch mint for coining gold was established here in 1838, which up to March 31, 1861, when it was closed by the civil war, produced 1,206,954 pieces, valued at \$5,048,641 50. It was reopened in 1869, and up to June 30, 1872, \$50,751 63 in unparted bars were produced. The total deposits to that date amounted to \$5,118,644 89. Under the coinage act of 1873, this establishment ceased to be operated as a mint, but is continued as an assay office. Charlotte contains several schools, churches, and cotton factories, and three banks with an aggregate capital of \$700,000. It has two daily, two tri-weekly, and four weekly newspapers, and a monthly periodical. The "Mecklenburg Declaration of Independence" was adopted here, May 31, 1775. The British troops occupied Charlotte in 1780, and for a time it was the American headquarters.

CHARLOTTE, a S. W. county of New Brunswick, Canada, bounded W. by Maine, S. W. by the St. Croix river, and S. by the bay of Fundy and Passamaquoddy bay; area, 1,323½ sq. m.; pop. in 1871, 25,882, of whom 10,703 were English in origin or descent, 10,154 Irish, and 4,319 Scotch. The town of St. Stephen is the highest point to which boats can ascend the St. Croix, which is 2 m. wide at its mouth. The county is traversed by the Western Extension, a part of the North American and European, and by the New Brunswick and Canada railways. The soil is adapted to all kinds of agricultural produce found in this latitude; but the inhabitants are largely employed in ship building, fisheries, and commerce. St. Andrews, the county town, is situated at the mouth of the St. Croix.

CHARLOTTE AMALIE, a town of the West Indies. See SAINT THOMAS.

CHARLOTTE AUGUSTA, commonly called Princess Charlotte, daughter of Queen Caroline and George IV., born at Carlton house, Jan. 7, 1796, died at Claremont, Nov. 6, 1817. At an early age she was placed under the care of the bishop of Exeter and Lady Clifford, and became one of the most accomplished princesses of her day. The prince of Orange was proposed to her as husband, but she bestowed her affections upon Prince Leopold of Saxe-Coburg, who in 1831 became king of Belgium. She married him May 2, 1816, and they took up their residence at Claremont, where she died after having been delivered of a stillborn child. Her death caused universal grief in England. It was said that by proper treatment the life of the mother at least might have been saved; and the physician who had attended her committed suicide in despair. Some of her letters, published in the "Quarterly Review," 1873, give a touching account of her unfortunate domestic life previous to her marriage.

CHARLOTTE HARBOR, or **Boca Grande**, an inlet on the W. coast of Florida, in Manatee co., about 25 m. long, and from 8 to 10 m. wide, but only 10 or 12 ft. deep. Its entrance, which lies between Boca Grande key and Gasperilla bay, is three quarters of a mile wide and 6 fathoms deep. This harbor is sheltered from the sea by islands, and produces fine oysters and a great variety of fish and wild fowl.

CHARLOTTENBURG, a town of Prussia, in the province of Brandenburg, on the left bank of the Spree, connected with Berlin by a fine promenade 4 m. long, which is lighted at night; pop. in 1871, 19,518. The place takes its name from Sophia Charlotte, the queen of Frederick I., who shortly before her death in 1705 caused a palace to be built there. The park, which is always open to the public, contains Rauch's recumbent statue of the queen, one of the finest works of modern art. Frederick the Great added a new chateau, and endowed it with a valuable gallery of art, which, especially the part which contained the paintings, was injured during the occupation of the

Royal Palace, Charlottenburg.

place by the Austrians and Russians in 1760. There are fine gardens connected with the palace. The town is a favorite resort and summer residence of the Berliners.

CHARLOTTESVILLE, a town of Virginia, capital of Albemarle co., on Moore's creek, 2 m. above its entrance into Rivanna river, and 65 m. N. W. of Richmond; pop. in 1870, 2,838, of whom 1,473 were colored. It is on the Orange, Alexandria, and Manassas, and the Chesapeake and Ohio railroads. It is the seat of the university of Virginia, an institution planned by Thomas Jefferson, founded in 1819, and whose buildings were erected at an expense of over \$200,000. (See VIRGINIA, UNIVERSITY OF.) A tri-weekly and two weekly newspapers are published here.

CHARLOTTETOWN, the capital of Prince Edward Island, in Queen's co., on the N. side of East river and on the strait of Cumberland, 42 m. N. W. of Pictou, Nova Scotia; pop. in 1871, 8,807. The site, looking toward the south, rises gently from the water. The harbor is good. The colonial building is of Nova

Scotia freestone. Among the other principal buildings are the post office, court house, market, athenæum, public hall, and normal school; the Prince of Wales, St. Dunstan, and Methodist colleges; a convent, lunatic asylum, government house, exchange, and jail. The town is lighted with gas. Here is an office of the New York, Newfoundland, and London telegraph company. Tri-weekly steamers ply during the season of navigation to Shediac and Pictou, and weekly to Georgetown, Port Selkirk, Crapaud, Mount Stewart, Port Hope, and Hawkesbury; a ferry steamer crosses the East river to Southport every hour. Communication with New Brunswick is made in winter by a small boat from Cape Traverse to Cape Tormentine, 9 m. distant. Large exports of all kinds of grain except wheat are made, to which are added potatoes, fish, and pork.

CHARLTON, a S. E. county of Georgia, bounded N. E. by the Satilla river, and separated from Florida on the S. E., S., and S. W. by St. Mary's river; area, 1,000 sq. m.; pop. in 1870, 1,897, of whom 401 were colored. Okefenokee swamp occupies the W. part. The surface is level and sandy. Tar and turpentine are manufactured. The chief productions in 1870 were 23,250 bushels of Indian corn, 3,474 of oats, 18,008 of sweet potatoes, 16,110 lbs. of rice, and 118 bales of cotton. There were 228 horses, 2,044 milch cows, 4,737 other cattle, and 6,075 swine. Capital, Trader's Hill.

CHARMA, **Antoine**, a French philosopher, born at La Charité, department of Nièvre, Jan. 15, 1801, died in Caen, Aug. 5, 1869. At the recommendation of his friend Victor Cousin, he was appointed about 1831 to the chair of philosophy at the faculty of Caen, which, despite charges of infidelity brought against him by Montalembert, he held till his death. His principal works are: *Essai sur les bases et les développements de la moralité humaine* (1834); *Leçons de philosophie sociale et de logique* (2 vols., 1838-'40); *Essai sur la philosophie orientale* (1842); and *Du Sommeil* (1851).

CHARON, in Greek mythology, son of Erebus and Night, the ferryman who transported the souls of the dead over the river Acheron to the infernal regions. The fee exacted for this service from each spirit ferried over by him was never less than one obolus, nor more than three; and to provide for this fee small coins were placed in the mouth of the dead. The spirits of those whose bodies had not been buried were not permitted to enter Charon's boat without having previously wandered on the shore for a century; nor could any living person be admitted into it till he had shown its master a golden branch, the gift of the Cumæan sibyl. The ferryman was once imprisoned for a whole year for having conveyed Hercules across in violation of this rule, even though he had been compelled by the hero to do so. Charon is generally represented as a robust old man of stern countenance, his eyes glowing like flame, his hair white and bushy,

and in his hands an oar to direct his boat on her course. The myth of Charon seems to

Charon.

have been of late invention, for he is not mentioned by any of the early Greek poets.

CHAROST, Armand Joseph de Béthune, duke de, a French philanthropist, a descendant of Sully, born at Versailles, July 1, 1728, died in Paris, Oct. 27, 1800. He devoted himself to the improvement of agriculture and of the condition of the laboring classes, emancipating the peasants on his estates, and promoting their education. His influence was extensive, and Louis XV. himself acknowledged his services. When France was exposed to invasion during the revolution, the duke, although he had little sympathy for the new government, contributed a large sum of money for the common defence. Nevertheless he was arrested and his property confiscated, but he escaped the guillotine.

CHARRAS, Jean Baptiste Adolphe, a French officer and military writer, born at Pfalzburg, in the department of Meurthe, June 7, 1810, died in Basel, Switzerland, Jan. 23, 1865. He was early imbued with republican principles, took part in the revolution of 1830, and was promoted in 1833 to the rank of lieutenant. Having written a series of able articles in the *National* on military affairs, which gave umbrage to the government, he was sent to Algeria, and distinguished himself there on the battle field as well as in the training of native troops and the colonization of the country; but owing to his unpopularity with Louis Philippe's government, he was only, after much delay, promoted to the rank of lieutenant colonel. After the revolution of 1848 he became under-secretary of state, and representative for the department of Puy-de-Dôme. He was one of the most zealous members of the national assembly, one of the chief supporters of the republican government, and one of the victims of the *coup d'état* of Dec. 2, 1851. First detained at Ham, he was transported to Belgium in January, 1852. In November, 1854, he was expelled from that country, at the request of

Napoleon III., whom Charras had denounced on many occasions, and most effectively in a letter of which 50,000 copies were printed in Belgium alone. He then sought refuge in Holland, and subsequently took up his residence in Switzerland. A pamphlet, *Les trois maréchaux de France* (Brussels, 1853), is also attributed to him. A remarkable work from his pen, *Histoire de la campagne de 1815*, in which he severely criticises the generalship of Napoleon I., appeared in 1857-'8 (2 vols.; 6th ed., 1869). His *Histoire de la guerre de 1813 en Allemagne*, unfinished at his death, appeared at Leipsic in 1866.

CHARRIÈRE, or **Charrières, Isabelle Agnète de Saint-Hyaacinthe de**, a French authoress, born at Utrecht, Holland, about 1740, died near Neuchâtel, Switzerland, Dec. 27, 1805. She was the daughter of a Dutch baron, and married M. de Charrière, a poor Swiss gentleman who had been her brother's teacher. She published her first novel, *Lettres neuchâteloises*, in 1784, and in 1786 appeared her most famous work, *Caliste, ou lettres écrites de Lausanne*. She visited England and France, and was an intimate friend of Benjamin Constant until the latter transferred his friendship to Mme. de Staël. She was a beautiful and brilliant woman; and Sainte-Beuve alludes in the highest terms to her genius in his *Galerie de femmes célèbres*. Owing to the loss of part of her fortune and friends, she spent the latter part of her life in great seclusion. A new edition of her *Caliste* appeared in 1845, with a notice by Sainte-Beuve, and with the latter's essay on *Benjamin Constant et Madame de Charrière*. Among her other writings are *Lettres de Mistress Henley*, a sequel to Benjamin Constant's *Mari sentimental*; *Aglionette et Insi-nuant*, a story; and the plays *L'Emigré*, *Le toi et le vous*, *L'Enfant gâté*, and *Comment le nommet-on*. Under the pseudonyme of Abbé de la Tour she published *Les trois femmes*, *Sir Walter Finch et son fils William*, and other works, of which a complete edition appeared in Leipsic in 1798. Many of her works have been translated into German by her friend Ludwig Ferdinand Huber, and she wrote some of them in that language.

CHARRON, Pierre, a French author, born in Paris in 1541, died there, Nov. 16, 1603. He studied law at Orleans and Bourges, and had practised for some years as an attorney when he took holy orders, and soon became noted for his eloquence as a preacher. He filled several ecclesiastical offices in Gascony and Languedoc, was appointed chaplain of Queen Margaret of Navarre, and in 1588 returned to Paris, intending to become a monk, but was rejected on account of his age. Remaining a secular priest, he went to Bordeaux, and there became intimately acquainted with Montaigne. Charron is the author of two books widely different in their tendency and character. His *Traité des trois vérités* (1594) is a defence of religion against atheists, of Christianity against

other religions, and of Catholics against heretics. In 1601, under the tolerant rule of Henry IV., Charron published his *Traité de la sagesse* (latest edition by Duval, Paris, 1821). To this work, unjustly branded by his contemporaries as atheistic, Charron owes his place in the history of modern philosophy.

CHARTER (Gr. *χάρτης*, parchment; Lat. *charta*), the name given in the middle ages to every kind of written convention. Among the principal kinds were *charta jurata* or *sacramentales*, by which an engagement was contracted with an oath; *charta de mundeburde*, by which kings, lords, or bishops granted their protection to corporations, churches, or monasteries; *charta apennes*, or *pantocharta*, by which titles to property were confirmed; *charta beneficiaria*, by which kings and emperors bestowed donations; and *charta partita* or *indentata*, which were common in England and France, and were marked with indentations or cut asunder, as English bank notes are now, in order to guard against counterfeits. The term came gradually to be limited to its modern sense, meaning an instrument by which a king or other sovereign power conferred or confirmed rights and privileges. Thus many of the early colonies in America had charters from the king of England, by which they were permitted to establish a government and make laws for their own regulation, which was therefore called a charter government. Among the charters of greatest historical importance are the *Magna Charta*, the basis of English liberty, which was signed by King John in 1215, and was frequently violated and confirmed by subsequent kings (see *MAGNA CHARTA*); the charter of peace, which Philip Augustus of France signed in 1222 at Melun, and which settled the relations between the royal officers and the officers of the bishop and chapter of Paris; the Norman charter, granted by Louis X. in 1315, to confirm the rights and privileges which Normandy had enjoyed under its ancient dukes, and which was not abolished till 1789; the

constitutional charter, which was the fundamental law of the French realm under the restoration, promulgated by Louis XVIII. in 1814, and which made all authority and executive power reside in the person of the king, and gave legislative power to two chambers; and the French charter of 1830, by which the national sovereignty was proclaimed, which was voted by the chamber of deputies, Aug. 7, 1830, and accepted by King Louis Philippe on the following day. In England corporations formerly owed their franchises to the king's charter, and the right in boroughs of sending members to parliament had or was supposed to have the same origin; but these franchises are now conferred by act of parliament.—In the United States acts of legislatures creating municipal and other corporations are commonly called charters. In the case of Dartmouth College *v.* Woodward (4 Wheaton's Reports, 518), it was decided by the supreme court of the United States that the charter of a private corporation was to be regarded as a contract, to which the state granting it was one party and the corporators the other; and consequently the provision in the constitution of the United States which forbids the states to pass laws impairing the obligation of contracts, would preclude its alteration or repeal by legislative action without the consent of the corporators. In consequence of this decision, the right to alter, amend, or repeal is usually reserved in such charters; and in some states by constitutional provision it is only subject to such right that they can be granted. The charters of public corporations, however, are at all times subject to legislative authority. (See *CORPORATION*.)

CHARTERHOUSE (Fr. *Chartreuse*, a Carthusian convent), a celebrated modern school and charitable foundation for aged soldiers and merchants in the city of London. The site it occupies was bought for a public burial place, during the great plague of 1349, by Sir Walter Manny, who afterward established on it a con-

Charterhouse.

vent of Carthusians. After the dissolution of the religious houses by Henry VIII. it passed through several hands, till at length it was bought by Thomas Sutton, who built a hospital and endowed the present foundation. The mastership of the Charterhouse is generally filled by some distinguished scholar, and the school has the repute of being among the first classical schools of England. The establishment supports 42 boys as pupils, and 80 pensioners, who must be at least 50 years old. Each boy is educated at a certain expense, and each pensioner receives food, clothing, lodging, fire, and a stipend of money. The right of presentation to the Charterhouse is vested by rotation in the 16 governors of the hospital. Nine church livings are also in their immediate gift. Besides the scholars upon the foundation, there are usually 60 or 70 others who pay. In 1872 extensive repairs and alterations were made in the buildings.

CHARTER PARTY, the name given to a contract by which the owner of a vessel lets the whole or a part thereof to another person, called the charterer, for the conveyance of goods. The charterer either hires the vessel for a cargo to be provided by him and carried by the owner, in which case the owner will provide, victual, and pay the captain and crew; or the contract may give him possession thereof for the voyage, with the usual rights and liabilities accompanying possession. It is implied in the contract that contraband goods are not to be taken on board, thereby rendering the vessel liable to seizure.

CHARTIER, Alain, a French writer, born in Bayeux toward the close of the 14th century, died probably in Avignon in or after 1449. He completed his education at the university of Paris, and was intrusted with several missions during the latter part of the reign of Charles VI., and afterward was attached to Charles VII. in various capacities. Although he had not taken holy orders, he received a prebend and archdeaconship in the cathedral of Paris. Among his principal works may be mentioned *Le livre des quatre dames*; *Le quadrilogue invectif*, a kind of colloquy between France, the people, the nobility, and the clergy; and *L'Espérance, ou consolation des trois vertus*, written in 1428. He was called by his contemporaries the father of French eloquence.

CHARTISM, a political creed in England, which takes its name from a proposed charter or bill of rights, known as the "people's charter," drawn up in 1838, the principal points of which were universal suffrage, vote by ballot, paid representatives, abolition of property qualification for representatives, annual parliaments, and equal electoral districts. These were the essential points, and are known as the six points of chartism. They had been previously advocated separately or two or more of them in conjunction; but chartism, as a distinctive political creed, took its rise in the wide-spread distress and popular disappoint-

ment that followed the adoption of the reform bill of 1832. The movement in favor of chartism was attended in many instances by popular outbreaks and riots, which were promptly suppressed by the government, and many prominent chartists were imprisoned and transported. The last disturbances occurred about the time of the French revolution of 1848, since which time chartism as an organization has gradually died out, the last public meeting having been held in 1857. Two of the six points have since been adopted: the abolition of the property qualification of members of parliament, in 1858, and the vote by ballot, in 1872.

CHARTRES, a city of France, capital of the department of Eure-et-Loire, 45 m. S. W. of Paris; pop. in 1866, 19,442. It is situated on the railroad running S. W. from Paris, and is

Cathedral of Chartres.

built on a slope at the bottom of which runs the river Eure, which divides the town into two parts, connected by a bridge planned by Vauban. Upon the site of the former fortifications are fine boulevards, and some of the modern buildings are well built; but the general appearance of the city is not prepossessing, most of the streets being narrow and crooked. The great object of interest is the cathedral of Notre Dame, commenced about 1020, and dedicated in 1260, though one of the spires was not finished till the 16th century. The principal front presents two square towers surmounted by two lofty octagonal pyramids. The old spire, of plain architecture, but cased with stone carved like the scales of a fish, is 374 ft. high. The new spire is 413 ft. high, built in the florid style. The rich portals, the painted

glass windows, the beautiful choir adorned with valuable works of art, and other remarkable features, combine to make this church one of the most magnificent in the world. It was covered with an iron roof in 1841, the old framework having been burned some years before. There are several other churches in Chartres, and among the public buildings and institutions are the residence of the prefect, three hospitals, a fine botanical garden, a museum, a library of 30,000 volumes, a departmental college and a normal school, a theatre, an agricultural society, and a charitable institution established by Dr. Aligre, whose name it bears, with accommodations for 200 aged poor and for 100 poor children. The town carries on an active trade in the products of the country, has an important wool market, and manufactories of woollen goods, hosiery, leather, and machinery. It derives its chief commercial importance from its corn market, which is the best regulated in France, and the management of whose business is intrusted to a corporation of women.—In antiquity Chartres bore the name of Autricum, but was also known as Carnutum Civitas, being the chief town of the Carnutes. In the middle ages it was the capital of the territory of Beauce, and gave its name to a county, which Francis I. raised to the dignity of a duchy. As such it was later the apanage of princes of the house of Orleans. It was often besieged and captured, among others by Henry IV. (1591), who was crowned there (1594).

CHARTRES, Robert Philippe Louis Eugène Ferdinand d'Orléans, duke de, a French prince, second son of the late duke of Orleans and grandson of Louis Philippe, born in Paris, Nov. 9, 1840. Having lost his father at the age of two, he lived with his mother, the duchess Hélène, at Eisenach, Germany, till after the revolution of Feb. 24, 1848, when he joined his relatives in England. In 1860 he accompanied his elder brother, the count de Paris, to the East; and in the following year to the United States, where they served on the staff of Gen. McClellan till July, 1862, after which they returned to England. During the Franco-German war he distinguished himself on the staff of Gen. Chanzy, under the assumed name of Robert le Fort. M. Thiers promoted him, after the abrogation of the decree of banishment of the Orleans family, to the rank of major, gave him the cross of the legion of honor, and permitted him to remain an honorary officer of the French army, in which capacity he has served in Algeria since 1872. In 1863 he married his cousin, Françoise Marie Amélie d'Orléans, eldest daughter of the prince de Joinville, by whom he has four children. He has published *Souvenirs de voyages* (1869), and an introduction to his father's posthumous *Campagnes de l'armée d'Afrique de 1835 à 1839* (1870).

CHARTREUSE, the name of various Carthusian monasteries, chiefly situated in France and Italy. The most famous institution of the

kind is La Grande Chartreuse (*Cartusia*), in the department of Isère, France, situated in a picturesque but wild and desolate region, on the summit of a steep rock at an elevation of about 4,000 ft. above the level of the sea, 14 m. N. N. E. of Grenoble. This monastery is the residence of the general of the Carthusian order. It owes its origin to St. Bruno, who repaired with six disciples to this locality in the latter part of the 11th century. It derived its name from a neighboring hamlet called Chartreuse, and it has since been called Grande Chartreuse from being the fountain-head of all other monasteries of the order. The cell which was inhabited by St. Bruno has been converted into a chapel, in which service is performed day and night. In the chapter house are the portraits of the generals of the order and a marble statue

La Grande Chartreuse.

of St. Bruno. The buildings have repeatedly been destroyed by fire; those now in use were erected in 1678. During the first French revolution the monastery was stripped of its possessions, but in 1816 it was restored to its original destination. The number of its inmates, once 300, is now 120, who depend for their support partly upon raising cattle, but mainly on the profit arising from the manufacture of the famous *liqueur* which bears the name of the monastery, where it is distilled from aromatic herbs.

CHARTULARIES, in the ancient Latin church, record books of the various monasteries, convents, and other religious and ecclesiastical foundations. Anterior to the 10th century, the pope ordered them to be kept. Their contents relate to the possessions, rents, endowments, and other temporalities of the church.—**CHARTULARY**, or **CHARTULARIUS**, is the title of the keeper of charters and public documents. He also presided in ecclesiastical courts. In.

the Greek church, the word *chartophylax* is used to designate an officer of the same class, but more comprehensive functions.

CHARYBDIS AND SCYLLA, in Grecian mythology, two voracious monsters which dwelt opposite to each other, the former on the Sicilian and the latter on the Italian coast. Charybdis abode in a rock off the shore of Sicily, and thrice every day gulped down the waters of the surrounding sea, and thrice cast them up again. Scylla, whose den was in another rock on the Italian shore, was still more loathsome, having twelve feet and six long necks and mouths, each of which took a victim from every ship which passed within their reach.—In geography, Charybdis was a whirlpool on the coast of Sicily, and Scylla a rock on the coast of Italy, whose proximity rendered the navigation of the Messinian strait peculiarly dangerous to the sailors of antiquity. The rock of Scylla is still to be identified, near the town of the same name (Scilla); but the site of Charybdis has been by modern geographers transferred to the whirlpool of Galoforo, 10 m. S. of Scilla, instead of being directly opposite. There are numerous counter-currents in the strait of Messina which produce whirlpools, but none of them are now dangerous.

CHASE, an E. central county of Kansas, watered by the Neosho river and its affluents; area, 757 sq. m.; pop. in 1870, 1,975. The Atchison, Topeka, and Santa Fé railroad traverses it. The chief productions in 1870 were 47,261 bushels of wheat, 104,626 of Indian corn, 26,748 of oats, and 8,605 tons of hay. There were 1,189 horses, 1,201 milch cows, 4,730 other cattle, 1,255 sheep, and 585 swine. Capital, Cottonwood Falls.

CHASE, Ira, D. D., an American clergyman, born at Stratton, Vt., Oct. 5, 1793, died at Newtonville, Mass., in November, 1864. He was educated at Middlebury college and Andover theological seminary, and was ordained in 1817. After laboring as a Baptist missionary in the western part of Virginia, he became in 1818 professor in the theological school at Philadelphia, which was soon after transferred to Washington. In this office he remained seven years, one of which he spent in Europe, and in 1825 he was prominent in establishing the theological school at Newton Centre, Mass., with which he was connected as professor till 1845, when he resigned, in order to devote himself to theological and literary studies. During a visit to Europe in 1830 he aided in founding the Baptist mission in France. He published "The Life of John Bunyan," "The Design of Baptism," "The Work claiming to be the Constitution of the Holy Apostles, revised from the Greek," "Infant Baptism an Invention of Man," and many sermons, essays, and contributions to reviews on questions of church history and doctrine.

CHASE, Philander, an American clergyman, born in Cornish, N. H., Dec. 14, 1775, died at Jubilee college, Illinois, Sept. 20, 1852. He

graduated at Dartmouth college in 1795. His religious views at this time were those usually held by the Congregationalists, but having met with a prayer book of the Episcopal church and carefully examined its contents, he studied for the ministry in that church, and was ordained in New York in May, 1798. For several years he was occupied in missionary labors in various parts of the state of New York. In 1805, on account of his wife's health, he went to New Orleans, where he labored zealously in behalf of the Episcopal church. Returning to the north in 1811, he became rector of Christ's church, Hartford, Conn. Deeply interested in the religious condition and prospects of the great west, he went in 1817 to Ohio, and entered into the work of planting and building up the church in that state. He became bishop of Ohio Feb. 11, 1819, and prosecuted his labors amid many severe trials; but feeling the necessity of educational influence and power, he visited England in 1823 to ask for pecuniary aid toward founding a college and theological seminary in Ohio. He collected about \$30,000, and on his return purchased 8,000 acres of land and laid the foundations of Kenyon college and Gambier theological seminary. Disputes having arisen between the bishop and some of his clergy in regard to the proper use of the funds obtained from England, he resigned in September, 1831, his jurisdiction in Ohio and the headship of the college. Intent upon missionary labor, he removed further west, and in 1835 was chosen bishop of Illinois. He again visited England, and collected about \$10,000 for the same purpose as before. His labors culminated in the founding in 1838 of Jubilee college at Robin's Nest, Illinois, where he spent the remainder of his life. He was a man of more than average ability, of indomitable perseverance, and great strength of will, and was the most energetic and successful pioneer of the Episcopal church in the west. His publications are: "A Plea for the West" (1826); "The Star in the West, or Kenyon College" (1828); "Defence of Kenyon College" (1831); and "Reminiscences," an autobiography, containing the principal events in the author's life to 1847 (2 vols. 8vo, 1848).

CHASE, Salmon Portland, an American statesman and jurist, born in Cornish, N. H., Jan. 13, 1808, died in New York, May 7, 1873. In 1815 his father removed to Keene, and died two years later. When 12 years old he went to Worthington, Ohio, where his tuition was superintended by his uncle, Philander Chase, then bishop of Ohio. He then entered Cincinnati college, and after about a year's residence there returned to his mother's home in New Hampshire, and in 1824 entered the junior class of Dartmouth college, where he graduated in 1826. In the succeeding winter Mr. Chase opened a school for boys in Washington. In 1829 he was admitted to the bar of the District of Columbia, for which he had qualified himself while discharging the duties of a teacher.

In 1830 he returned to Cincinnati. While struggling through the early embarrassments of professional life, he prepared an edition of the statutes of Ohio, with copious annotations, and a preliminary sketch of the history of the state (3 vols. 8vo). This edition soon superseded all previous publications of the statutes, and is now received as authority in the courts. Aided by the reputation thus acquired, he soon gained a valuable practice, and in 1834 became solicitor of the bank of the United States in Cincinnati, and not long after of one of the city banks. In 1837 he acted as counsel for a colored woman claimed as a fugitive slave, and in an elaborate argument, afterward published, controverted the authority of congress to impose any duties or confer any powers in fugitive slave cases on state magistrates, and maintained that the law of 1793 relative to fugitives from service was void, because unwarranted by the constitution of the United States. The same year, in an argument before the supreme court of Ohio in defence of James G. Birney, prosecuted under a state law for harboring a negro slave, Mr. Chase asserted the doctrine that slavery was local and dependent on state law for existence and continuance, and insisted that the person alleged to have been harbored, having been brought within the territorial limits of Ohio by the individual claiming her as master, was thenceforth in fact and by right free. In 1846 he was associated with William H. Seward as defendant's counsel in the case of Van Zandt before the supreme court of the United States, and argued more elaborately the principles which he had advanced in former cases, maintaining that under the ordinance of 1787 no fugitive from service could be reclaimed from Ohio unless there had been an escape from one of the original states; that it was the clear understanding of the framers of the constitution that slavery was to be left exclusively to the disposal of the several states, without sanction or support from the national government; and that the clause in the constitution relative to persons held to service was one of compact between the states, and conferred no power of legislation on congress, and was never understood to confer any.—Prior to 1841 Mr. Chase had taken little part in politics. He had voted sometimes with the democrats, but more commonly with the whigs, who in the north seemed to him more favorable to anti-slavery views than their opponents. In 1841 he united in a call for a convention of the opponents of slavery and slavery extension, which assembled at Columbus in December. This convention organized the liberty party of Ohio, nominated a candidate for governor, and issued an address to the people written by Mr. Chase, defining its principles and purposes. In 1843 a national liberty convention assembled at Buffalo. Mr. Chase was an active member of the committee on resolutions, to which was referred a resolution proposing "to regard and treat the third clause of the constitution, whenever applied to

the case of a fugitive slave, as utterly null and void, and consequently as forming no part of the constitution of the United States, whenever we are called upon or sworn to support it." He opposed the resolution, and the committee refused to report it. It was, however, afterward moved in the convention by its author, and adopted. In 1845 Mr. Chase projected a southern and western liberty convention, designed to embrace "all who, believing that whatever is worth preserving in republicanism can be maintained only by uncompromising war against the usurpations of the slave power, and are therefore resolved to use all constitutional and honorable means to effect the extinction of slavery within their respective states, and its reduction to its constitutional limits in the United States." The convention was held in Cincinnati in June, 1845, and Mr. Chase, as chairman of the committee, prepared the address, giving a history of slavery in the United States, showing the position of the whig and democratic parties, and arguing the necessity of a political organization unequivocally committed to the denationalization of slavery and the overthrow of the slave power. In 1847 he was a member of the second national liberty convention, and opposed the making of any national nomination at that time, urging that a more general movement against slavery extension and domination was likely to grow out of the agitation of the Wilmot proviso, and the action of congress and political parties in reference to slavery. In 1848, anticipating that the conventions of the whig and democratic parties would probably refuse to take ground against the extension of slavery, he prepared a call for a free territory state convention at Columbus, which was signed by more than 3,000 voters of all political parties. The convention thus called was largely attended, and invited a national convention to meet at Buffalo in August. This convention, over which Mr. Chase presided, nominated Martin Van Buren for president, and Charles Francis Adams for vice president.—On Feb. 22, 1849, he was chosen a senator of the United States from Ohio, receiving the entire vote of the democratic members of the legislature, and of those freesoil members who favored democratic views. The democratic party of Ohio, by the resolutions of its state convention, had already declared slavery an evil. Mr. Chase, coinciding with the democrats in their general views of state policy, supported their state nominees, distinctly announcing his intention, in the event of the party's desertion of its anti-slavery position in state or national conventions, to end at once his connection with it. When the nomination of Mr. Pierce by the Baltimore convention of 1852, with a platform approving the compromise acts of 1850, and denouncing the further discussion of the slavery question, was sanctioned by the democratic party in Ohio, Mr. Chase withdrew from it, and advocated the formation of an indepen-

dent democratic party. He prepared a platform, which was substantially adopted by the convention of the independent democracy at Pittsburgh in 1852. He supported the nominees and measures of the independent democracy until the Nebraska bill gave rise to a new and powerful party, based substantially upon the ideas he had so long maintained. In March, 1850, he delivered in the senate a speech against Mr. Clay's compromise bill, reviewing thoroughly all the questions presented in it. He moved an amendment providing against the introduction of slavery in the territories to which the bill applied, but it failed by a vote of 25 to 30. He proposed also, though without success, an amendment to the fugitive slave bill, securing trial by jury to alleged fugitive slaves, and another conforming its provisions to the terms of the constitution, by excluding from its operation persons escaping from states to territories, and *vice versa*. In 1854, when the bill for the repeal of the Missouri-Kansas bill, was introduced, he drafted an appeal to the people against the measure, and in a speech on Feb. 3 attempted the first elaborate exposure of the features of that bill, as viewed by its opponents. In the general opposition to the Nebraska bill he took a leading part, and made an earnest protest against it on the night of its passage. Meanwhile he was constant in the discharge of the general duties of his position as senator. To divorce the federal government from all connection with slavery, to confine its action strictly within constitutional limits, to uphold the rights of individuals and of the states, to foster all the great interests of the country, and to secure an economical administration of the national finances, were the general aims which he endeavored to promote. He held that the federal treasury should defray the expense of providing for the safety of navigation on our great inland seas, as well as on the Atlantic and Pacific coasts, and urged liberal aid by the federal government to the construction of a railroad to the Pacific. He was an earnest supporter of the policy of the free homestead movement, and of cheap postage.—In July, 1855, Mr. Chase was nominated by the opponents of the Nebraska bill and the Pierce administration for governor of Ohio, and was elected. His inaugural address, delivered in 1856, recommended economy in the administration of public affairs, single districts for legislative representation, annual instead of biennial sessions of the legislature, and ample provision for the educational interests of the state. His state policy and senatorial course were now so much approved that at the national convention of the republican party, held the same year, a majority of the Ohio delegation and many delegates from other states desired his nomination for the presidency; but his name was at his request withdrawn. In 1857 he was re-elected by the largest vote that had ever been

given for a governor in Ohio. In the republican national convention at Chicago, May, 1860, Mr. Chase was proposed as a candidate for the presidency, and on the first ballot received 49 votes out of 465. In 1861 he became secretary of the treasury in President Lincoln's cabinet, and retained the position till June 30, 1864, when he resigned. The financial policy which carried the nation through the civil war was mainly the work of Mr. Chase. Its essential features were the issue of United States notes, known as greenbacks, which bore no interest, but were made legal tender; borrowing money upon bonds maturing at various dates, and bearing different rates of interest payable in gold; and the so-called national banking system, under which each bank was required to deposit in the treasury \$100 in bonds for every \$90 of notes issued by it, and which, superseding state banking systems, secured at once stability to the currency and to the national credit. A large amount of the bonds first issued bore 7-3 per cent. interest (2 cts. a day on each \$100), but the great majority were at 6 per cent. None were sold at less than par, and they generally commanded a premium. When Mr. Chase left the treasury department, the national debt amounted to \$1,740,690,489, to which it was estimated \$500,000,000 would be added in case the war continued another year. Mr. Taney, chief justice of the United States, having died in October, 1864, Mr. Chase was appointed his successor Dec. 6. In this capacity, in March, 1868, he presided at the trial of President Johnson, who had been impeached before the senate by the house of representatives. Mr. Chase had now become dissatisfied with the policy of the republican majority in congress. He was proposed in the democratic national convention held in New York in July, 1868, as a candidate of that party for the presidency. He was willing to accept the nomination upon certain conditions, and for a time it seemed probable that he would be very strongly supported; but in the actual ballots his highest vote was 4 out of 663. From that time he withdrew to a great extent from public affairs, his health having been much impaired by a paralytic stroke; but in the presidential canvass of 1872 he sided with the party opposed to the reelection of Gen. Grant as president.

CHASE, Samuel, an American jurist, and one of the signers of the declaration of independence, born in Somerset co., Maryland, April 17, 1741, died June 19, 1811. His father, an Episcopal clergyman of English birth, directed his early education, and sent him to study law at Annapolis, where he was admitted to the bar at 20 years of age. He was soon noted as a skilful and eloquent advocate and a learned lawyer. He strenuously opposed the royal governor and his adherents in the colonial legislature, was among the most vehement in resisting the stamp act, and soon became the leader of the friends of liberty in his state. The

Maryland convention sent him as one of five delegates to the continental congress of 1774, and he continued a member of successive congresses until the end of 1778. In 1776 he went with Charles and John Carroll on a mission to Canada, which he was the more ready to undertake, because the Maryland convention was inclined to half-way measures and refused to instruct its delegates to vote for the declaration of independence. On his return he canvassed the state, brought public opinion to bear on the convention, and having thus caused the passage of the desired resolution, returned to Philadelphia in season to vote for independence. He was appointed on most of the important committees in congress, where his industry was unwearied. The last two or three years of the war he spent at home in the practice of law. In 1783 he went to England as commissioner of Maryland, to recover funds invested previously to the war in the bank of England. He remained there nearly a year, and succeeded in putting the claim so far in the way of adjustment that subsequently \$650,000 was paid over to that state. In 1786 he removed to Baltimore, and in 1788 was appointed chief justice of a newly established criminal court there, and in 1791 chief justice of the general court of Maryland. Between these dates he was a member of the Maryland convention for considering the federal constitution, which he did not think sufficiently democratic. His course on the occasion of a riot in 1794 characterizes the man. He had caused the arrest of two popular men as ringleaders. They refused to give bail, and the sheriff was apprehensive of a rescue should he take them to prison. "Call out the posse comitatus, then," said the judge. "Sir," was the reply, "no one will serve." "Summon me, then; I will be the posse comitatus, I will take them to jail." Such was the state of the public mind that the grand jury, instead of presenting the rioters, presented the judge for holding a place in two courts at the same time. He simply told them that they had meddled with topics beyond their province. In 1796 Washington appointed him an associate justice of the supreme court. In 1804 the house of representatives, at the instance of John Randolph, impeached him for misdemeanor in the conduct of several political trials, particularly those of Fries and Callender, convicted of seditious libels five years before. The senate discharged him, March 5, 1805, a majority being in his favor on five of the eight charges, and a majority against him on the residue. After his discharge, he resumed his seat on the bench, which he retained until his death.

CHASLES, Michel, a French mathematician, born at Épernon, Nov. 15, 1793. After the completion of his studies in 1814 at the polytechnic school of Paris, he removed to Chartres, where he obtained a professorship in 1825. He subsequently returned to Paris, where in 1841 he was appointed professor of geodesy

and machinery in the polytechnic school, and in 1846 of superior geometry, a chair especially established for him in the faculty of sciences. In 1851 he became a member of the academy. In 1867 he reported to that body his possession of alleged autograph letters of Galileo, Pascal, and Newton, containing startling revelations, and claiming for Pascal the merit of Newton's most celebrated discoveries. These letters were part of about 27,000 which Chasles purchased from a M. Irène Lucas for 140,000 francs, including about 2,000 pretended to have been written by Rabelais, and others by Mary Stuart, Shakespeare, Dante, Petrarch, and Julius Cæsar, and by emperors, poets, saints, and statesmen of various countries and eras. Though these documents were spurious, with the exception of about 100, Chasles, Élie de Beaumont, and Balard regarded the whole of them as genuine, and Charles Dupin insisted upon their being published by the government. Lucas was sentenced, Feb. 23, 1870, to two years' imprisonment for forgery and fraud. The principal works of Chasles are: *Aperçu historique sur l'origine et le développement des méthodes en géométrie* (Paris, 1837; German translation by Sohneke, Halle, 1839); *Sur l'attraction des ellipsoïdes* (1837 et seq.); *Histoire de l'arithmétique* (1843); *Sur l'attraction des corps de forme quelconque* (1845); *Traité de géométrie supérieure* (1852; German translation by Schnuse, Brunswick, 1856); and *Traité des sections coniques* (1865 et seq.)

CHASLES, Victor Euphémion Philarète, a French author, cousin of the preceding, born at Mainvilliers, near Chartres, Oct. 8, 1798, died in Venice, Aug. 3, 1873. In 1815, while a printer's apprentice, he was arrested on charge of entering into a political conspiracy. Having been released through the influence of Chateaubriand, he went to London, and entered the employment of Valpy, the classical publisher, and during seven years acquired great familiarity with English literature, and afterward on the continent with that of Germany. Later he visited other parts of Europe and the United States. Having returned to Paris in 1823, his contributions to periodicals and the *Journal des Débats* gave him the reputation of an accomplished literary critic. In 1827 he shared with Saint-Marc Girardin an academical prize for his essay on French language and literature in the 16th century. In 1837 he was appointed director of the Mazarin library, and in 1841 professor of the Germanic languages and literature in the collège de France. In 1870 he returned to this chair, after having filled for some time that of the languages and literature of southern Europe, during the exile of the regular incumbent, Edgar Quinet. His *Études de littérature comparée* treats, in about 20 separate volumes (1847-'64), of the literature of antiquity, of the middle ages, of Spain and Italy, of the English revolution, of the literature and civilization of England, of the Uni-

ted States, &c. He wrote books of travels and tales; prepared editions of the classics and of Molière; and made a number of translations from English and German.

CHASSÉ, David Hendrik, baron, a general of the Netherlands, born at Thiel in Gelderland, March 18, 1765, died in Breda, May 2, 1849. He entered the army at an early age, and having at first joined the party of the patriots, fled to France on their defeat, and engaged in the French service. In 1793 he had attained the rank of lieutenant colonel, and went with Pichegru to Holland, where he was engaged against the English. Subsequently he served in the French army in the peninsula, and acquired a reputation for desperate bravery. King Louis conferred a title on him for his conduct at Ocaña, and he was afterward made lieutenant general for services in the passes of the Pyrenees. After the peace he went into the Dutch service, and distinguished himself in the battle of Waterloo. When the Belgians declared for separation, Baron Chassé was sent to Antwerp, and on the entrance of the revolutionary bands into the city he retired into the citadel (Oct. 27, 1830), consenting to an armistice. This was broken by the Belgians, whereupon Chassé bombarded that part of the town where the insurgents lay. In December, 1832, he defended Antwerp against the French, and on the capitulation of the fortress he was retained as a hostage, and removed to Dunkirk, but permitted to return to Holland after the signing of the preliminary treaty, May 12, 1833. Made a general of infantry in reward for his services at Antwerp, he spent most of his remaining years on his estate in Gelderland.

CHASSELOUP-LAUBAT. I. François de, marquis, a French soldier, born at St. Sernin, near Marennes, Aug. 18, 1754, died in Paris in October, 1833. Descended from a family of soldiers, he became one of the most skilful military engineers of his day. Declining to emigrate with his fellow noblemen, he rendered eminent service to the republic. He conducted the engineering operations at Maestricht in 1794, at Mentz in 1795, and in the Italian campaigns of 1796 and 1799. Charged shortly after with planning a new system of defensive operations, he strengthened the fortifications of Alessandria and made it the principal arsenal of the French. He planned the sieges of Colmar, Dantzic, and Stralsund, and was active in almost all the campaigns of Napoleon, including that of 1812 in Russia; after which he was appointed senator. During the hundred days he swore allegiance to Louis XVIII., who subsequently made him a marquis. As one of the judges of Marshal Ney, he was opposed to his execution. **II. Justin Prudent de**, count, and afterward marquis, son of the preceding, born in Paris in 1802, died there, Dec. 17, 1863. He had attained the rank of brigadier general when the department of Seine-Inférieure returned him in 1849 to the

legislative assembly, and Louis Napoleon rewarded him for his services by promoting him to be general of division in 1853 and grand officer of the legion of honor in 1859. **III. Justin Napoléon Samuel Prosper de**, marquis, brother of the preceding, born in Alessandria, Italy, during the French occupation of that city, March 29, 1805, died in Paris, March 31, 1873. He early entered the civil service, and in 1830 was sent as assistant commissioner to Algeria. In 1837 he was elected to the chamber of deputies, and subsequently became councillor of state. In 1849 he was returned to the legislative assembly, and remained a member of the legislature during Louis Napoleon's administration, of which he was a staunch supporter; and in 1851 he was for a time minister of marine. In 1858 he became a member of the colonial board established in connection with the new ministry of Algeria and colonies, presiding over it during nearly the whole period of its existence (1859-'60); after which he had charge of the portfolio of marine and colonies, and was made a senator. He instituted important measures for the improvement of maritime and colonial affairs, and displayed much activity as president of the French geographical society, and as a contributor to the *Revue des Deux Mondes*. In 1869 he officiated as minister, presiding over the council of state until the accession of Ollivier's administration, Jan. 2, 1870. His old constituents of Charente-Inférieure returned him to the national assembly in February, 1871. Called upon by that body to prepare a bill for the reorganization of the army, he submitted an important report on the subject in March, 1872.

CHASSEPOT, Antoine Alphonse, a French inventor, born March 4, 1833. Like his father, he became a workman in manufactories of arms, and becoming connected with those belonging to the government, he was made comptroller in 1858, and director in 1864. He acquired celebrity by inventing the rifle known by his name, which had occupied his attention for many years, though it was not adopted for the army until after the success of the Prussian needle gun in the campaign against Austria in 1866, when the necessity of having a similar arm to rival that of the Germans led to the hasty introduction of the Chassepot rifle in the French infantry and part of the cavalry. Chassepot derives a large income from the patent on his invention, and a lawsuit instituted in 1869 by M. Manceaux contesting his right to it proved unsuccessful. (See RIFLE.)

CHASTEL, Jean. See CHÂTEL.

CHASTELAIN, or Chastellain, Georges, surnamed the Adventurous, a French chronicler and poet, born at Alost, Flanders, in 1403, died in Valenciennes, March 20, 1475. He belonged to a noble family, studied and travelled extensively, became acquainted with the principal personages of his day, and about 1443 left the army to enter the service of Philip the Good, duke of Burgundy, and was employed by him in household duties and providing for his amusements,

as well as in political and diplomatic missions. On the death of Philip in 1467, he remained in the service of his son and successor Charles the Bold, who in 1473 made him knight of the golden fleece. He was one of the most prominent writers of his day, and his most famous work is *La grande chronique, ou livre de tous les hauts et grans faits de la Chrétienté souverainement de ce noble royaume de France et de ses dépendances, depuis Van vingt* [1420] *jusques à maintenant* [1474], edited by Buchon in the *Panthéon littéraire* (Paris, 1837). His other writings deal with various historical subjects, and include some poetry. Kervyn de Lettenhove published in Brussels in 1863 *Œuvres de Georges Chastellain*.

CHASTELARD, or Châtelar, Pierre de Boscobel de, a French poet born about 1540, died in 1563. He was a nephew on his mother's side of the chevalier Bayard. He was handsome, young, a distinguished performer in the tilt yard, famous for his skill with the sword, an excellent dancer, a delicate musician, and a poet of some note in the French court during Mary Stuart's residence in that country. He was one of the French gentlemen who, as attachés of Marshal Damville's household, accompanied her on her return to her native land, and fell in love with her. He dedicated a poem to her, which, according to Brantôme, was answered by Mary, who also allowed him to accompany her on the flute when she sang, had frequent interviews with him, and, as Knox says, was so familiar with him, early and late, "that scarcely could any of the nobility have access to her." Whether warranted or not, the poet thought his addresses were encouraged by the queen, and concealed himself in her bedroom on the night of Feb. 12, 1563. He was discovered and ejected, and the queen, as soon as she heard of the occurrence, ordered him with a sharp reprimand to quit her court. Chastelard, however, four days later again concealed himself within a recess in her bedchamber at Burnt Island, where the queen stopped to spend the night on her way to Dunfermline and St. Andrews; and while her women were undressing her, he rushed out before them all and attempted, it is said, to plead for pardon. The screams of the queen and the ladies brought Murray, whom she conjured, in the first transports of fear and indignation, to "put his dagger into the villain." Murray, however, reminded his sister that he should be dealt with according to the laws of the realm. He was accordingly brought publicly to trial at St. Andrews, sentenced to death, and executed; the queen remaining inaccessible to all appeals for mercy. On mounting the scaffold he recited Ronsard's hymn of death, and as he was about to die he cried aloud, "Adieu, most lovely and cruel of princesses!" The most detailed relation of the tragic story is to be found in the writings of John Knox.

CHASTELEB, Jean Gabriel Joseph Albert, marquis de, an Austrian general, born in the

castle of Mulbaes, in Hainaut, Jan. 22, 1763, died in Venice, March 10, 1825. He was descended from the ducal family of Lorraine. In 1778 he entered the Austrian service, and served in the war of the Bavarian succession, and in 1789 in the war against the Turks. In 1792 he defended the citadel of Namur for 14 days against the French, and was taken prisoner, but exchanged the next year, and highly distinguished himself in the succeeding campaigns, reaching the rank of general. In 1795 he bore an active part in the third partition of Poland, and in 1798 was sent as envoy to St. Petersburg to engage Czar Paul in a second coalition against France. In 1799 he was quartermaster general in the Russo-Austrian army in Italy, and was dangerously wounded before Tortona. In the following years he repeatedly commanded in the Tyrol, distinguishing himself chiefly during the general uprising of 1809, when he gained considerable advantages over the ablest French generals. Napoleon, in an order of the day, styled him the chief of the brigands, and directed that if captured he should be brought before a court martial and shot within 24 hours. He was at length, May 13, 1809, completely routed at Wörgl by the French under Marshal Lefebvre, and made his escape to Hungary with only a handful of followers. After the treaty of Vienna he was made commandant of Troppau, then governor of Theresienstadt, and in 1813 of Dresden. When in 1815 the Lombardo-Venetian kingdom was established, he was made governor of Venice, which post he retained until his death. A monument to his memory was erected in Venice by the Austrian government.

CHASTELLUX, François Jean, marquis de, a French military officer and man of letters, born in Paris in 1734, died there, Oct. 28, 1788. At an early age he entered the army, and distinguished himself in Germany during the seven years' war, and afterward in America, where he served as major general in the army of Rochambeau, and where his amiable character gained for him the friendship of Washington. The work which established his literary reputation was entitled *De la félicité publique*, published in 1772. The leading idea of this work was the progress of the human mind as understood by Condorcet and his friends. It is wanting in plan and method, and noted for its bitterness against Christianity. It is now simply regarded as a literary curiosity, although considered by Voltaire as superior to Montesquieu's *L'Esprit des lois*. The *Voyages dans l'Amérique Septentrionale*, published in 1786, contains his journal written while travelling from Newport to Philadelphia, and thence to Saratoga and Portsmouth, and also his journal of travels in Virginia. It has notices of the natural history of the country, interesting details concerning the localities and events of the war of the American revolution, and observations on the character of the principal heroes of that war. It is in an agreeable and lively style,

sometimes eloquent and sometimes frivolous, and is valuable as conveying the impressions made by our revolution upon an intelligent foreigner. The most interesting portion is the account of Mr. Jefferson, whose guest he was at Monticello. Only 24 copies were printed, but an English translation was published in London, with maps and engravings (2 vols. 8vo, 1787). His *Discours sur les avantages et les désavantages qui résultent pour l'Europe de la découverte de l'Amérique* appeared in 1787, and resolved the question, which had been proposed by Raynal, in favor of the advantages. It was praised by La Harpe as the best of the works of Chastellux.

CHASUBLE (low Lat. *casubula*, from *casula*, a hut), the outer vestment worn by Catholic priests in the celebration of mass. It was originally common to both civilians and churchmen, and consisted of a circular piece of cloth with an opening for the head in the centre. Those among the Greeks who have retained it call it very properly *planeta*, because it can be turned on every side by the wearer. It long retained its circular form in the British islands, as is evident from the iconographic monuments of the middle ages. At Rome, however, and throughout all the adjoining countries, it soon became modified, on account of its exceeding inconvenience. It was either slit or folded up beneath the arms of the celebrant; and finally it has assumed the form, which is now universal in the Latin church, of an oblong piece of silk with a hole in the middle for the head, and falling down to the knees before and behind. It must be of silk, and the color varies with the festivals.

CHAT, a genus of warblers (*icteria*), placed by Baird in the subfamily *sytleicolinae*. The best known species is the yellow-breasted chat (*I. viridis*, Bonap.). The bill is shorter, stronger, and more curved than in the typical warblers, in this respect more nearly resembling the vireos and the shrikes. The upper parts are olive-green; under parts and inside of wings gamboge-yellow for anterior half of body; rest of under parts white, tinged with brown on the sides; forehead and sides of head ash; lores and region below the eyes blackish; a white stripe from the nostrils over the eye; patch on lower lid, and stripe from side of lower mandible, white; bill black. Female like the male, but smaller. Length 7.4 in., tail 3.3, wing 3.25. It is found over the eastern United States to the Missouri, and south to Guatemala. The long-tailed chat (*I. longicauda*, Lawr.) differs from the above chiefly in having the tail nearly half an inch longer; it may be only a western variety. They are very noisy birds, jealous of intruders, and apparently scolding in a great variety of notes. The food consists principally of insects. They are most abundant in the middle and southern states, and are peculiar to America. (See **STONE CHAT**.)

CHATEAUBRIAND, François Auguste, viscount de, a French author and statesman, born at

St. Malo in September, 1768, died in Paris, July 4, 1848. He sprung from a noble family which was known in Brittany as far back as the 10th century. He passed his childhood on his patrimonial estate of Combourg, and received his education at the colleges of Dôle and Rennes. When he was 17 years old he received a commission as second lieutenant in the army, and was two years later promoted to a captaincy. About the same time he was presented at court, introduced to the fashionable world, and became acquainted with La Harpe, Fontanes, and other eminent writers. His first production, an idyllic poem, *L'amour de la campagne*, revealed nothing of the genius which he afterward manifested. The revolutionary movements which agitated Paris induced him to embark for the United States in the spring of 1791, with a view to seeking for the northwest passage. He landed at Baltimore, and repaired immediately to Philadelphia, where he delivered to President Washington a letter of introduction from the marquis de La Rouairie. The young traveller dined with the president, who in the course of conversation made allusion to the obstacles his guest was exposed to meet in his intended expedition. "But, sir," said the traveller, "it is less difficult to discover the polar passage than to create a nation, as you have done." Chateaubriand then visited New York, Boston, and Albany, and went among the Indian tribes, living with them, and exploring the country bordering on the great lakes. He afterward travelled through Florida, and spent some time among the Natchez. These peregrinations among the savages, the strange beauties of the American continent, the immensity of its rivers, the solitude of its forests, made a powerful impression upon his imagination. Nearly a year had thus been passed when an English newspaper which he found in a log cabin informed him of the flight and arrest of Louis XVI., and he returned to France in order to place himself at the disposal of the king. Finding on his arrival at Paris that by his presence there he could not benefit the royal cause, but endangered his own life, he joined the emigrants at Coblenz. Before leaving France, however, he married Mlle. Céleste Delavigne Buisson, an excellent woman, who during her long life was his faithful but rather neglected wife. Having enlisted in a company who followed the Prussian army in their invasion of France, he was wounded while skirmishing in the vicinity of Thionville; at the same time he had a severe attack of smallpox, and was left nearly dead on the road. A charitable person took care of him, and he was carried to Jersey, where he recovered his health. In 1793 he went to London, where he lived in an unfurnished garret, without fire, sometimes without food, happy when he was able to earn something by giving French lessons or making translations for booksellers. In 1797 he published his *Essai historique, politique et moral sur les révolutions anciennes et*

modernes, considérées dans leurs rapports avec la révolution française; it was rather unsuccessful in England and entirely ignored in France. He was then of a skeptical and somewhat materialistic turn of mind; but, being recalled to religious convictions by the dying appeal of his mother, he framed the plan of his *Génie du Christianisme*, and, encouraged by Fontanes, whom he had met in London, engaged in writing it. About this period he succeeded in re-entering France under an assumed name, and supported himself by literary work, while completing the *Génie du Christianisme*. The episode of *Atala*, which was incorporated in this work, was published separately in the *Mercure de France* in 1801, and excited much attention. The *Génie du Christianisme*, published in 1802, was the signal of a literary and moral revolution, and greatly contributed to the revival of religious principles in France. Bonaparte, being pleased with the book, appointed the author secretary of the French legation at Rome in 1803, and he was promoted in 1804 to the office of chargé d'affaires; but the execution of the duke d'Enghien put an end to his friendly intercourse with Napoleon. He resigned his office, and afterward assailed the emperor most bitterly. In 1806 he visited Greece, Asia Minor, Palestine, and Egypt, and on his return retired to a small villa situated in the Vallée aux Loups, near Paris, where he composed *Les martyrs*, the most admired of his works, which was published in 1809. The notes of his travels were subsequently arranged to form the *Itinéraire de Paris à Jérusalem*. In 1811 he was made a member of the French academy, as the successor to Marie Joseph Chénier, but some difficulty as to his reception speech prevented his taking his seat, which he did not occupy till after the restoration. This was hailed with enthusiasm by Chateaubriand, who as early as March 30, 1814, had published a political pamphlet, *De Bonaparte et des Bourbons*, which was eagerly sought for and did excellent service to the king's cause. This was his first step in politics; and "this new life of his," Sainte-Beuve says, "may be divided into three parts: 1, from March 30, 1814, to June 6, 1824, the period of pure royalism; 2, from June 6, 1824, when he was dismissed from the cabinet, to the end of the restoration, the period of liberal opinion, in flagrant opposition with the foregoing; 3, the period of mixed royalism and republicanism subsequent to the revolution of 1830, when Chateaubriand, for conscience sake, said to the duchess of Berry, 'Your son is my king,' while at the same time befriending Carrel and Béranger, and preparing himself beforehand for the coming republic." On the first return of the Bourbons, Chateaubriand was appointed ambassador to Sweden; but before he had departed for his post, Napoleon reappeared in France, and Chateaubriand followed Louis XVIII. to Ghent, became a member of his cabinet, presented him with his *Rapport sur l'état de la France*, and

was on the second restoration appointed minister of state and peer of France; but having assailed, in the pamphlet *De la monarchie selon la charte*, the celebrated decree by which the *chambre introuvable* was dissolved, he forfeited the royal favor and lost his office. He now joined the ultra-royalist opposition, and became one of the principal editors of the *Conservateur*, the most powerful organ of that party. In 1820 he was reconciled with the court on occasion of the assassination of the duke of Berry, and wrote his *Mémoires* of that prince. In the same year he was appointed minister to Berlin, and in 1822 ambassador to London. He was one of the plenipotentiaries at the congress of Verona, where he was instrumental in bringing about the French expedition to Spain. On his return to France he was appointed minister of foreign affairs, but being unable to agree with the prime minister, M. de Villele, he was summarily dismissed, June 6, 1824. This time, instead of returning to his old associates, he joined the liberal opposition. He now proved himself the most ardent supporter of the freedom of the press, and eloquently advocated the independence of Greece, by which he acquired great popularity. On the fall of Villele in 1828 he was made ambassador to Rome, but resigned on the formation of the Polignac cabinet. After the revolution of 1830 he manifested the most chivalric devotion to the duke of Bordeaux, notwithstanding his grievances against the family and his attachment to the principles of liberty. He was at that time, as he said himself, "a Bourbonist from the point of honor, a royalist by reason, a republican by taste and disposition." He now ceased to take any active part in politics, and even abandoned his seat in the chamber of peers, but occasionally published bitter pamphlets against the new government, in which he defended the rights of the fallen dynasty. In 1833 judicial proceedings were instituted against him on account of his *Mémoire sur la captivité de la duchesse de Berry*; but he was acquitted by the jury. He also repeatedly visited the exiled Bourbons at Prague. These occasional bursts of political passion interfered but little with his literary pursuits. As early as 1831 he had published his *Études, ou discours historiques*, which were but an introduction to a history of France on a plan of vast proportions; unhappily, age and pecuniary embarrassments prevented his finishing the work. He completed, however, some lighter but more profitable performances; his *Essai sur la littérature anglaise*, followed by a literal translation of Milton's "Paradise Lost," commanded general attention, while his *Congrès de Vérone* was eagerly read by the students of political history. From 1834 he devoted most of his time to completing an autobiography, which he called *Mémoires d'outre-tombe* (12 vols., 1849-'50; new illustrated ed., 8 vols., 1856, and 6 vols., 1861; German translation, 2d ed., Jena, 1852). This work he sold in advance

in 1836, and afterward lived on the annuity which was secured to him by the proceeds. His life was spent in retirement, the drawing room of his friend Mme. Récamier being almost the only place he visited. There he could be seen every evening among the *élite* of the literary world, receiving the homage to which he was entitled by his character, genius, and renown. A profound melancholy, however, invaded his latter years. He who had so often foretold the coming of the republic in France, witnessed its accession in 1848, but he died amid the desolation brought over the capital by the bloody struggle of June. Most of his works have been translated into the English, German, and other languages. The complete and separate editions are numerous. The best of the former is by Sainte-Beuve (12 vols., 1859-'61), with a review of his literary labors. Part of a new and complete illustrated edition, to consist of 14 volumes, has appeared since 1864. Marin's *Histoire de la vie et des ouvrages de M. de Chateaubriand* appeared in 1833, and M. Villemain's *Chateaubriand, sa vie, ses écrits, son influence sur son temps*, &c., in 1858, in 2 vols.

CHÂTEAUBRIANT, Françoise de Foix, countess de, a mistress of Francis I. of France, born about 1485, died Oct. 16, 1537. A scion of the illustrious house of Foix, she repaired at an early age to the court of Louis XII., and became the wife of the count de Châteaubriant. She was in the zenith of her beauty when Francis I. ascended the throne. Notwithstanding the jealous temper of her husband, the king was soon on intimate terms with the beautiful countess, who publicly wore jewelry given to her by her royal lover, bearing mottoes which his sister Margaret had written at his request. The royal favor served the interests of her brothers as well as her own ambition. Her husband, however, resented her faithlessness by frequently inflicting upon her corporal punishment. Her relations with the king lasted for a number of years, and until the defeat of Pavia (1525) and the captivity of Francis her influence over him was unbounded; but on his return from Madrid she was supplanted by Anne de Pisseleu, afterward duchess d'Étampes. The rest of her life was spent with her husband in the now dismantled castle of Châteaubriant. A chamber is still pointed out in which, according to tradition, she was bled to death by her husband. This, however, is not supported by any positive evidence, although his brutal treatment of her was notorious.

CHÂTEAUDUN, a town of France, in the department of Eure-et-Loir, on the left bank of the Loir, 25 m. S. of Chartres and 30 m. N. W. of Orleans; pop. in 1866, 6,781. It is prettily situated on a commanding elevation, and contains a fine square and promenade, and a number of handsome public buildings. The principal churches are the Madeleine and St. Valérien, built in the 12th century. The most conspicuous edifice is the ancient castle of the counts

Dunois, built on a rock and surmounted by a high tower, with a famous staircase and other curious appendages. The trade is mainly in the local agricultural and industrial products, including nails, cordage, leather, woollen and silk goods, hosiery, and hats. The viscounts of Châteaudun ruled here from the 11th to the 15th century, when the last of them dying childless, Duke Charles of Orleans became the local ruler; he relinquished his supremacy in favor of his natural brother John, the bastard of Orleans, famous for his exploits in the wars with England. The town was destroyed by fire in 1723, and rebuilt on an improved plan. During the war of 1870-'71 the French were defeated here by Gen. Willich, who soon after took the town by assault, Oct. 18, 1870.

CHÂTEAU-GONTIER, a town of France, in the department of Mayenne, on the river Mayenne, 18 m. S. of Laval; pop. in 1866, 7,364. The town has a Gothic church, a communal college, public baths, and manufactures of linen, woollen, and leather. In October, 1793, the insurgent royalists gained here a great victory over the republicans.

CHÂTEAUGUAY, a S. W. county of the province of Quebec, Canada, bordering on the St. Lawrence, and traversed by the Châteauguay, the Noire, and other streams; area, 249½ sq. m.; pop. in 1871, 16,166, of whom 11,288 were French, 2,496 Scotch, and 1,937 Irish. The soil is fertile and the surface presents little variety of level. The battle of Châteauguay or of Chrysler's farm was fought in this county, Oct. 26, 1813, between Col. de Salaberry of the Canadian voltigeurs and Gen. Wilkinson of the American army, who intended to invade Canada by the Grand Isle which divides the river St. Lawrence opposite Coteau du Lac. The Canadians were victorious. Chief town, Ste. Martine.

CHÂTEAUGUAY, Steur de. See LE MOYNE.

CHÂTEAUROUX, a town of France, capital of the department of Indre, on the left bank of the Indre and on the railway from Paris to Bordeaux, 160 m. S. S. W. of Paris; pop. in 1866, 17,161. It has a theatre and public library. There is an old castle on an eminence above the Indre, a gloomy building, in which the princess de Condé, niece of Richelieu, died in 1692, after having been imprisoned there for nearly 23 years. Châteauroux is one of the principal cloth manufacturing places of central France, the wools produced in Berry being almost exclusively used in the fabrication. There are various other manufactures, and important wool and iron fairs are held here. There is a government tobacco manufactory, in which 1,000 persons are employed.

CHÂTEAUROUX, Marie Anne, duchess de, a favorite of Louis XV., born about 1718, died Dec. 8, 1744. She was a daughter of the marquis de Nesle, lost her mother in 1729, and following her example as well as that of three of her sisters, she became in 1742, after the death of her husband the marquis de la Tournelle,

the principal mistress of Louis XV., who conferred upon her (Oct. 20, 1743) the title of duchess de Châteauroux, with a large domain and a pension of 80,000 francs. With her sister Mme. de Lauraguais she joined the king during the war of 1744, and notwithstanding the insults which were heaped upon her by the soldiers, she followed him to Lille, Ypres, Dunkirk, and Metz, when the king during his illness was prevailed upon to expel her ignominiously from his presence. After his return to Paris, she consented to be reconciled to him only on condition that her principal persecutors, including the bishop of Soissons and La Rochefoucauld, should be banished from Paris, and that the minister Maurepas, who had addressed her as the incestuous La Tournelle, should make a humble apology. Soon afterward she died suddenly, amid terrible convulsions, charging Maurepas with having poisoned her. She squandered immense amounts of public money, spent 1,200,000 francs upon her palace at Choisy, and displayed great frivolity and recklessness in other respects. A collection of her letters was published in Paris in 1806, and Sophie Gay wrote a novel entitled *Madame le duchesse de Châteauroux* (2 vols., 1834-'9).

CHÂTEAU-THIERRY, a town of France, in the department of Aisne, on the right bank of the Marne, and on the Paris and Strasburg railway, 45 m. N. E. of Paris; pop. in 1866, 6,519. It is a pretty town, laid out in the form of an amphitheatre, with handsome promenades, and united by a fine stone bridge with a suburb on the other side of the Marne. The church of St. Crispin resembles a fortress, and possesses great archæological interest. La Fontaine was born here, and a marble statue has been erected to his memory. There are two medicinal springs in this town, which attract many visitors in summer. The manufactures are unimportant, but the trade in agricultural products, cattle, and wool is exceedingly active, the surrounding region being the most fertile of the ancient province of Champagne.—The settlement and name of the town originated from a feudal castle built in 720 by Charles Martel as a residence for the youthful Thierry IV., of which vestiges are still visible. It was captured by the English in 1421, and by Charles V. in 1544; and Henri de Guise received a wound here in 1574 whence he was called *le balafre*. A duchy since the 16th century, the town continued to be the capital of Brie-Champenoise till the revolution of 1789. A memorable battle was fought here Feb. 12, 1814, in which Napoleon defeated the Russians and Prussians under Sacken.

CHÂTEL, Ferdinand Toussaint François, abbé, a French religious reformer, born at Gannat, Jan. 9, 1795, died in Paris, Feb. 13, 1857. His parents were poor, and he was apprenticed to a tailor; but his parish priest, pleased with the boy's religious zeal, defrayed the expenses of his education. He was ordained as a priest in

1818, and became vicar at Moulins and elsewhere, and afterward was chaplain in the army till about 1830. Having acquired celebrity as a preacher, and written in favor of theological reforms, he attempted in 1831 to found a new sect, based upon natural religion, venerating Christ only as a model man, doing away with the confessional, fasting, and vows of chastity, and substituting French for Latin in the liturgy. He was consecrated as the primate of the so-called French Catholic church, which gained many adherents. He was not molested by the authorities till 1842, when his places of worship were closed. After the revolution of Feb. 24, 1848, he reopened them and came forward as a champion of women's rights. In 1850 the authorities again put an end to his public performances, but he remained faithful to his convictions to the last. He was employed as a metropolitan postmaster in the latter part of his life. His principal publications are, *Profession de foi de l'église catholique française* (Paris, 1831), and *Le code de l'humanité, ou L'Humanité ramenée à la connaissance du vrai Dieu et au véritable socialisme* (1838).

CHÂTEL, Jean, a French fanatic, born in Paris about 1575, executed Dec. 29, 1594. He was the son of a rich shopkeeper, and studied divinity under the Jesuits, and philosophy in the university of Paris. He regarded Henry IV. as a heretic who reigned without the sanction of the pope, and was impelled by religious fanaticism to stab him on Dec. 27, 1594, in the apartment of the royal palace occupied by Gabrielle d'Estrées, the king's mistress, inflicting a slight wound with a knife upon the upper lip of the king and knocking out one of his teeth. Though it was believed that he had been instigated by the Jesuits, who were consequently for a short time expelled from Paris, he declared to the last, and while he was undergoing torture, that he had acted entirely of his own accord. His remains were mutilated and dragged through the streets after his execution. A colossal pyramid was erected on the site of the house which he had inhabited, as an expiatory memorial of his crime; but it was subsequently demolished upon the demand of Père Cottin, who regarded the inscription upon it as disparaging to the society of Jesus.

CHÂTELET (Lat. *Castellucium*), the name of two fortresses which existed in Paris in former times, said to have been built by Julius Cæsar. The Grand Châtelet was restored and enlarged by Louis IX., Charles VIII., and Louis XII., remodelled by Louis XIV., and demolished in 1802. It stood on the right bank of the Seine, in the locality now occupied by the western part of the place du Châtelet. It was the residence of the counts and afterward of the provosts of Paris, and became celebrated as a prison and as an important seat of the judiciary. At the time of the suppression of the latter in 1790, the court contained, from the

provost down to the ushers and policemen, 1,207 officers, besides a large number of lawyers who transacted business there, and the military forces of the Châtelet, which consisted of two companies of soldiers, part of whom were at the same time employed as ushers. The Petit Châtelet was situated on the left bank of the Seine, on the site of the present place du Petit Pont; swept away by an inundation in 1296, it was rebuilt in 1369, and demolished in 1782. Originally it was one of the gates of Paris, where tolls and excise duties were levied. The châtelets at Orleans and Montpellier were, like those of Paris, the seats of judicial bodies.

CHÂTELET, Madame du. See DU CHÂTELET.

CHÂTELLERAULT, a town of France, in the department of Vienne, on the right bank of the Vienne, and on the railway from Paris to Bordeaux, 18 m. N. N. E. of Poitiers; pop. in 1866, 14,278. It is one of the great centres of the manufacture of cutlery in France, which gives employment to about 600 families. There is also a national manufactory of side arms, established in 1820. There are important iron works, manufactories of jewelry, laces, and hardware. An active trade is carried on in the product of the country, and in lithographic stones obtained from the neighboring quarries. A fine stone bridge, constructed by order of Sully, and called by him Pont Henri IV., connects the town with the suburbs on the left bank of the Vienne. At the E. end of the bridge is a huge castle, flanked with four massive towers, with a lofty arch in the centre of the building, under which the high road enters the town.

CHATHAM. I. A central county of North Carolina, drained by Rocky and New Hope rivers, and traversed by the Haw and the Deep, which unite in the S. E. part to form the Cape Fear; area, 700 sq. m.; pop. in 1870, 19,723, of whom 6,830 were colored. The surface is diversified, and the soil fertile and clayey. There are extensive beds of coal in the vicinity of Deep river, which is navigable as far as the mines. The Chatham railroad traverses the county, and there is a railroad from Fayetteville to the coal fields. The chief productions in 1870 were 156,763 bushels of wheat, 304,881 of Indian corn, 124,632 of oats, 43,677 of sweet potatoes, 252,346 lbs. of butter, and 52,210 of tobacco. There were 2,561 horses, 1,470 mules and asses, 5,410 milch cows, 6,356 other cattle, 15,531 sheep, and 31,333 swine. There were 1 mining company, 1 foundery and machine shop, 1 iron manufacturing company, and 13 flour mills. Capital, Pittsboro. **II.** A S. E. county of Georgia, bordering on the sea, bounded S. W. by the Ogeechee river, and N. E. by the Savannah, which separates it from South Carolina; area, 358 sq. m.; pop. in 1870, 41,297, of whom 24,518 were colored. The surface is level, and partly occupied by swamps. Near the rivers the soil is fertile and productive; in other parts it is barren and sandy. It is the most populous county of the state. The

Georgia Central, the Atlantic and Gulf, and the Savannah and Charleston railroads traverse it. The chief productions in 1870 were 55,220 bushels of corn, 49,680 of sweet potatoes, 63 bales of cotton, 6,300 gallons of wine, and 8,808,064 lbs. of rice. There were 312 horses, 681 mules and asses, 908 milch cows, 723 other cattle, and 1,917 swine. There were 6 manufactories of brick, 2 of cars, 1 of gas, 5 of machinery, 5 printing establishments, 4 saw mills, 4 flour mills, 7 manufactories of carriages and wagons, 1 of fertilizers, 2 of iron castings, and 1 of marble and stone work. Capital, Savannah.

CHATHAM, the chief town of Kent co., Ontario, Canada, 176 m. S. W. of Toronto, and 47 m. E. of Detroit, Mich., situated on the river Thames, which enters Lake St. Clair about 18 m. to the west, and is navigable for small vessels; pop. in 1871, 5,873. The Great Western railway passes through the town, and there is steamboat communication with Detroit. Chatham is surrounded by a fine agricultural country, and has a large trade in agricultural produce. Oak and walnut timber and staves are exported in large quantities. In 1871, 199 Canadian steam vessels of 2,245 tons, and 57 sailing vessels of 6,871 tons, entered; also 21 United States steamers, of 2,850 tons, and 121 sailing vessels of 8,980 tons. Many fine sailing vessels have been built here. The town has agencies of the bank of Upper Canada and the Government bank.

CHATHAM, a town of Barnstable co., Mass., forming the S. E. extremity of Cape Cod, about 75 m. S. E. of Boston, and 5 m. from the Cape Cod railroad; pop. in 1870, 2,411. The inhabitants are chiefly engaged in the merchant marine and in fishing; 30 or 40 vessels are annually employed in the cod and mackerel fishery, and 15 or 20 in the coasting trade. There are 4 churches, 1 high school, 12 grammar and primary schools, 5 post offices, and a weekly newspaper. The Chatham lights are on James's Head, at the S. E. extremity of the town, in lat. 41° 40' 20" N., lon. 69° 57' 12" W. They are two in number, fixed, and 70 ft. above the sea. There is also a lighthouse showing a fixed light, known as Monomoy light, on Cape Malabar, a narrow sandy beach extending S. into the sea some 10 m. from the main body of the town.

CHATHAM, a town of New Brunswick, Canada, in Northumberland co., on the right bank of the Miramichi river, near its mouth in Miramichi bay; pop. in 1871, 4,203. It has a Roman Catholic cathedral, college, and hospital, a masonic and a temperance hall, and is lighted with gas. The north shore and the Quebec and gulf port steamers call weekly. The town is to be connected with the International railway. It is a port of entry, whence large quantities of lumber and fish are exported. In 1871 the arrivals were 174 British vessels of 39,390 tons; foreign, 54, of 25,803 tons; and the total departures were 210, of 57,966 tons.

CHATHAM, a parliamentary and municipal borough and naval arsenal of England, county of Kent, situated on the right bank of the Medway, near its confluence with the Thames, 30 m. S. E. of London, and adjoining Rochester, with a station on the East Kent railway; pop.

New Docks and Repairing Basin.

in 1871, 44,135, including about 8,000 dockyard men and soldiers. It includes the village of Brompton just below it, on the same side of the river. It is a dirty, ill-built, irregular town, with many wooden houses and few buildings of interest. Its great feature, and the sole cause of its importance, is the vast naval establishment at its lower end, commenced by Elizabeth, and improved by her successors, until it is now one of the finest in Great Britain. The dockyard, which is about a mile long, contains six building slips, wet and dry docks, a rope house 1,140 ft. long, blacksmith shops, steam saw mills, oar and block machinery by Brunel, copper sheathing and paint mills, pattern room, arsenal, &c. Several ships in ordinary are moored in the river. To the marine barracks are attached a ship-gun battery and school. There are also barracks for the royal engineers, sappers, and miners, with a school for young officers and recruits, where lectures are given upon everything relating to the art of war. There are good libraries for both services, and naval and military hospitals. Work was commenced on the new dockyards in 1861, and the repairing basin was completed in 1871. On the land side all the works are shut in by a strong line of fortifications, with several defences on the Chatham and Brompton sides, among which are Forts Pitt and Clarence between the former place and Rochester, Fort Gillingham, Upnor castle, across the river, now used as a magazine, and a strong redoubt on an eminence at the S. E. end of the yard. The houses within this enclosure, which belong to the village of Brompton, are tenanted

chiefly by persons employed in the yard. In 1667 the Dutch under De Ruyter, after destroying Sheerness, sailed up the Medway with 17 light ships and 8 fire ships, broke a chain stretched across the river, destroyed several sail of the line and a quantity of stores, in the face of a hot fire from Upnor castle, and retired with trifling loss, carrying off a ship of war named the Royal Charles. In the improved condition of the defences, it is believed that such an exploit would be impossible.

CHATHAM, Earl of. See PITT, WILLIAM.

CHATHAM ISLANDS, a group in the Pacific, belonging to Great Britain, E. of New Zealand, between lat. 43° 40' and 45° 20' S., and lon. 176° and 177° 20' W. They consist of Wairikaori, or Chatham island, from 80 to 90 m. in circumference; Rangihau-te, or Pitt island, 12 m.

long by 8 broad; and a number of others which are mere barren rocks. The W. shore of the largest island is undulating, and clad with vegetation to the water's edge; the N. shore is flat; the S. and part of the E. rocky and precipitous. There are several bays and some good harbors, which have been frequented by whalers ever since the discovery of the group by Broughton in 1791. Near the middle of the island is Tewanga lake, 25 m. long and 6 or 7 m. broad, S. of which the country is generally arable, the products being similar to those of New Zealand. The climate is mild and healthy. The aboriginal inhabitants are of the Malay race, and darker than the New Zealanders.

CHATI (*Felis mitis*), a leopard-like cat, smaller than the ocelots, with which it lives in South America. The general color is yel-

Chati (*Felis mitis*).

lowish white, with black irregular patches along the back, becoming lighter toward the sides; the tail is partially ringed with black. Though very gentle and almost domestic in captivity, it is very destructive in its native woods to small quadrupeds and birds; it prowls about hen roosts, and is one of the farmer's worst enemies. It sleeps or hides by day, and comes out at night; it is so active that no fence can keep it out, and so little that it can enter a very small aperture; it is also extremely wary and silent in its movements. Its native name is *chibigauzu*.

CHÂTILLON-SUR-SEINE, a town of France, in the department of Côte d'Or, on the railway from Paris to Mühlhausen, 110 m. S. E. of Paris; pop. in 1866, 4,860. The Seine divides it into two parts, one of which is called Bourg and the other Chaumont. Formerly they were both enclosed by separate walls and ditches and defended by a castle, which still remains in the quartier de Chaumont. An active trade is carried on in the products of the country, and the industrial establishments comprise manufactories of cloth, serge, hats, and woollen and cotton yarns, tan yards, bark and fulling mills, and important iron works. Marshal Marmont was born here, and built on the spot a fine château. In the 12th century the town was an important military station, and the residence of the early dukes of Burgundy. Previous to the first revolution it was the capital of the Pays de la Montagne, which formed part of the government of Burgundy. In February, 1814, a conference was held here between the representatives of Napoleon and the allied sovereigns. On Nov. 19, 1870, Ricciotti Garibaldi surprised here a detachment of the 14th German army corps, which suffered severe loss, and was forced to fall back upon Châteaivilain. The town contains remarkable antiquities.

CHÂTRE, La, a town of France, in the department of Indre, 20 m. S. E. of Châteauroux; pop. in 1866, 5,167. It is pleasantly situated on the left bank of the river Indre, and contains a primary tribunal and a communal college. The castle which defended it is now in ruins, but one of its towers is used as a prison.

CHATSWORTH, a celebrated estate in the parish of Edens, Derbyshire, England. A branch of the London and Northwestern railway leads from Manchester to Whaley bridge, and a coach from the latter place to Chatsworth. The place may also be reached by an omnibus from Rowsley, the terminus of a

branch of the Midland railway, which leaves from Ambergate. Chatsworth was among the domains given by William the Conqueror to William Peveril, his natural son. In the reign of Elizabeth it was purchased by Sir William Cavendish, who began to build a mansion here, which after his death was completed by his widow, the countess of Shrewsbury. The present building was nearly completed by the first duke of Devonshire, 1688-1706; a new wing was built by the sixth duke (died 1858), who greatly added to the beauty of the establishment. Chatsworth gardens are among the most famous in England. The grand conservatory is 300 ft. long, 145 ft. broad, and 65 ft. high, comprising an area of about an acre, with a carriage road in the centre. The great glass house of the *Victoria regia* lily was erected under the direction of Sir Joseph Paxton, the designer of the London crystal palace. The park is about 9 m. in circumference, and diver-

Chatsworth.

sified with hill and dale. South and southwest of the mansion are remarkable water works. The mansion, about 180 ft. square, is built around an open quadrangular court. The terraces in front are 1,200 ft. long. The state rooms, 190 ft. long, are full of paintings, carvings, and tapestries; the south galleries contain more than 1,000 drawings by foreign masters, and cabinet pictures. The principal works of art are sculptures by Thorwaldsen, Canova, Chantrey, and Westmacott, and paintings by Titian, Rembrandt, Murillo, and Landseer. Chatsworth house was for 13 years the prison of Mary Stuart. Hobbes also spent some time here. A "Handbook of Chatsworth and Hardwick" was published in 1846, by the then duke of Devonshire.

CHATTAHOOCHEE, a river of Georgia, which rises near the N. E. corner of the state, flows S. W. to West Point, thence nearly S., forming the boundary between the lower half of that state and Alabama, and unites with the Flint

to form the Appalachicola; length about 550 m. It is navigable for steamboats to Columbus, 300 m. from the gulf of Mexico.

CHATTAHOOCHEE, a S. W. county of Georgia, bounded N. by Utoy creek, and separated from Alabama on the W. by the Chattahoochee river; area, 250 sq. m.; pop. in 1870, 6,059, of whom 3,405 were colored. The surface is somewhat diversified. The chief productions in 1870 were 2,331 bushels of wheat, 107,453 of Indian corn, 16,136 of sweet potatoes, and 4,374 bales of cotton. There were 235 horses, 781 mules and asses, 896 milch cows, 2,042 other cattle, and 4,737 swine. Capital, Cusseta.

CHATTANOOGA, a city and the capital of Hamilton co., Tennessee, at the base of Lookout mountain, near where the S. boundary of the state touches Alabama and Georgia; pop. in 1870, 6,093, of whom 2,221 were colored. It is on the Tennessee river, 250 m. by water from Knoxville, and 150 m. S. E. of Nashville. The river is navigable by steamboats eight months of the year, and by small boats at all times. The Nashville and Chattanooga, East Tennessee and Georgia, Alabama and Chattanooga, and Western and Atlantic railroads connect here. There are two national banks, with \$470,000 capital, and a discount and deposit bank. It is the shipping point for most of the surplus productions of East and of a portion of Middle Tennessee, and contains a number of mills and factories. The surrounding country is supplied with water power, well wooded, and rich in coal and iron.—During the civil war Chattanooga was an important strategic point for the operations in eastern Tennessee and Georgia. After the engagement at Stone River, near Murfreesboro (Dec. 26, 1862, to Jan. 2, 1863), the confederates, under Bragg, fell back to Chattanooga, which they abandoned Sept. 8, upon the approach of Rosecrans. The confederates, being reinforced by Longstreet's division from the army of Virginia, manœuvred to drive Rosecrans from Chattanooga, while he attempted to force them from their threatening position in the neighborhood. The result was the battle of Chickamauga, fought Sept. 19, 20, about 12 m. S. W. of Chattanooga. (See *CHICKAMAUGA*.) After his repulse, Rosecrans continued to occupy Chattanooga, but was superseded (Oct. 19) by Thomas, and Grant was placed in command of the military division of the Mississippi, comprising the four departments commanded by Sherman, Thomas, Hooker, and Burnside. Bragg had despatched Longstreet to operate against Burnside near Knoxville, and meanwhile, by commanding the lines of supply, held Thomas practically besieged at Chattanooga. Grant reached Chattanooga Oct. 23, and at once formed plans for raising the siege. By a series of successful operations the lines of supply were opened, and soon after the middle of November the Union force at Chattanooga was raised to about 80,000, while the confederates had not more than 50,000. Grant now re-

solved to force the enemy from his commanding position, which lay in a semicircular form on the heights overlooking Chattanooga. Lookout mountain being on the south and Missionary ridge on the east. The operations began Nov. 23, when the confederate picket line was forced back, and favorable positions secured. On the morning of the 24th Hooker with 10,000 men was sent to assail the confederate left, strongly posted on the Tennessee upon the slopes of Lookout mountain. A dense fog covered the sides, concealing the movement from the enemy; and the confederates, taken by surprise, abandoned the position, with a loss of 2,000 prisoners. Hooker's force encamped for the night upon the upper part of the slope which they had won. This engagement is generally designated as the battle of Lookout mountain, sometimes as the battle above the clouds. Sherman was ordered on the morning of the 25th to assault the confederate centre and right, which occupied a long line on the heights of Missionary ridge, in a position so strong, that, as Bragg says, "though greatly outnumbered, no doubt was entertained of our ability to hold it, and every disposition was made for that purpose." Several determined attacks were repelled; but late in the afternoon three divisions of Thomas's army, under Sheridan, T. J. Wood, and Baird, stormed the ridge and broke the confederate line, when, says Bragg, "the enemy, having secured much of our artillery, soon availed themselves of our panic, and, turning our guns upon us, enfiladed our lines both right and left, rendering them wholly untenable. Fortunately it was now near nightfall, and the country and the roads in our rear were fully known to us, but unknown to the enemy. The routed left made its way back in great disorder. After informing myself of the full condition of affairs, it was decided to put the army in motion for a point further removed from a powerful and victorious army, that we might have some time to replenish and recuperate for another struggle." This action is generally known as the battle of Missionary ridge. The confederates were pursued for a space on the 26th. The Union loss during the three days was 5,616, of whom 757 were killed, 4,529 wounded, and 330 missing. The confederate loss in killed and wounded was smaller, probably not more than 4,000; but 6,142 prisoners were taken, together with 40 guns and 7,000 stand of small arms. The results of this action were on both sides recognized as of great importance. In effect, it put an end to the war in Tennessee for a year, when it was resumed there by Hood in the battles of Franklin and Nashville.

CHATTELS (law Lat. *catalla*), a term used to designate personal property. This is of two kinds: chattels personal, including movable goods, as domestic animals, money, harvested crops, &c.; and chattels real, under which term are included all interests in land which are less than freehold, that is to say, which are

not estates in fee or for life. Chattels, on the death of the owner without a will, pass to his personal representatives instead of his heirs at law, and they constitute the primary fund for the payment of debts. Chattels personal may be transferred by mere delivery, without writing; and chattels real did not at the common law require for their creation or assignment livery of seisin. Some things are either real estate or chattels according to circumstances. Thus, a house belonging to the owner of the land it is built upon constitutes a part of the freehold; but if owned by a mere tenant, who has a right to remove it, it is his personal chattel. So an unharvested crop may be a part of the realty or a chattel, according as it does or does not belong to the owner of the soil.

CHATTERTON, Thomas, an English poet, born in Bristol, Nov. 20, 1752, died in London, Aug. 24, 1770. His father, who was a school teacher, died three months before his birth. At five years of age he was sent to a charity school, but was withdrawn after a year and a half as an incorrigible dunce. His mother then, taking him in charge, attracted his curiosity by an old manuscript with illuminated capitals, from which he rapidly learned to read. He resolutely prosecuted his studies, mastered various treatises on antiquities and heraldry, and conceived the wildest dreams of ambition. Sent again to school in his eighth year to a pedant of poetry, he was almost the only pupil whom his master could not excite to poetical enthusiasm. In this school he remained seven years, veiling beneath an appearance of melancholy and incapacity the labor of an original mind, taking no interest in his associates, and devoting himself intensely to miscellaneous reading. In his 11th year he wrote verses, the fruits of painful elaboration, and chiefly of a satirical character. In his 12th year he completed the poem of "Elinoure and Iuga." His mother and sister, who seem to have been the only objects of his love, were surprised at his change to unwonted vivacity, and at the brilliant hopes which he expressed as well for them as himself. In 1767 he was apprenticed to an attorney in Bristol, and though laboriously occupied in the drudgery of copying, he yet found time to continue his study of history, theology, and especially antiquities and old English phraseology. In the next year he began his unparalleled series of literary impositions. A new bridge being finished at Bristol, he sent to a journal of the place an account of the ceremonies on opening the old bridge, which he pretended was taken from an ancient manuscript. Being questioned, he said he had found the parchments in the chest of a wealthy merchant of the reign of Edward IV., "Canynge's cofre," which, having been preserved in a room of the Redcliffe church, had in 1727 been broken open by proper authority, and some old deeds being taken from it, the remaining MSS. had been left exposed as of no value. Chatterton's father had taken a number of these parch-

ments to serve as covers for books in his school, and among those remaining the youthful poet affirmed that he had found many writings of Mr. Canynge and his friends, especially of Thomas Rowley, an ecclesiastic and poet. He was prepared to confirm his tale by several compositions which he had already finished, and by parchments which he had stained to resemble antiques. To a pewterer named Burgum, ambitious of heraldic honors, he gave a pedigree tracing his descent from the noble Norman family of De Bergham; to the historian of Bristol he presented an account of all the churches in the city as they appeared 300 years before, which he had drawn from the writings of the "gode prieste Thomas Rowley;" to a theologian he sent a fragment of a sermon on the Holy Spirit, as "wroten" by Rowley; to a wealthy citizen he presented a poem, the "Romaunt of the Cnyghte," written by one of his ancestors four centuries before. He contributed several fictitious poems to the "Town and Country Magazine" of London; and to Horace Walpole, then preparing his anecdotes of British painters, he sent an account of eminent "carvellers and peyncters" who once flourished in Bristol. He labored without a confidant, sleeping little, preferring to write by moonlight, since he believed that the presence of that planet added to his inspiration, roaming over the country on Sunday, lying in meadows, where in a sort of trance he would contemplate old churches and edifices, and nursing in solitude a wild and vain enthusiasm and a stoical pride of talent. The literary antiquaries, who had just been at war about the authenticity of Ossian, engaged in new controversy about the productions of Chatterton. Walpole was at first deceived by them, but having submitted them to Mason and Gray, the latter pronounced them to be forgeries. The result was that Walpole returned his MSS. to the young poet, who indignantly avenged himself by a bitter satirical attack. In his 17th year Chatterton was dismissed from his apprenticeship, and set off for London. He designed a literary career, but declared that if disappointed he would become a Methodist preacher, a founder of a sect, or would have the pistol for his final resort. He contributed to reviews and magazines; wrote political letters, sermons for clergymen, and songs for the public gardens; was introduced to the lord mayor Beckford, formed high expectations of influence as an opposition writer, and boasted that he "would settle the nation before he had done." At the death of Beckford soon after, he is said to have gone almost frantic; he dissipated his despair in elegies, removed to wretched lodgings, continued in his misery to remit presents to his mother and sister, to whom he had before announced his splendid hopes, suffered for want of food while with a gay exterior he frequented places of public amusement, retained his unconquerable pride and vanity, confided his distress to

no one, declined the invitation of his landlady to a dinner after he had been three days without food, spent his last penny for a dose of arsenic, and was found dead in his room surrounded by numerous manuscripts which he had torn into shreds. He was interred in the pauper burying ground of Shoe lane, and the citizens of Bristol have erected a monument to his memory. It was several years before he became an object of public interest, and the result of the discussion concerning the poems which he ascribed to Rowley and other old poets is the general belief that, however extraordinary it was for Chatterton to have written them, it was impossible for them to have been written in the 15th century. In a life of less than 18 years this misdirected genius made himself proficient in the most various studies, created the person, history, and language of an ancient poet, composed epics, tragedies, satires, elegies, ballads, and long narrative poems, and exhibited not only a facility of versification but a luxuriance of fancy and power of invention which promised him a high position among English poets. The early poems of Pope and Cowley are not comparable to those of Chatterton, and even the almost fabulous *Mirandola* was less precocious if not less great. Warton called him a "prodigy of genius;" Shelley acknowledged his "solemn agency;" Wordsworth names him "the marvellous boy;" Keats dedicated "*Endymion*" to his memory; and Alfred de Vigny has made him the subject of one of his finest dramas, in which he represents him as the type of suffering and unrequited genius. The personal appearance of Chatterton was proud, manly, and very prepossessing. His eyes were gray and piercing, and, as in the case of Lord Byron, one of them was more brilliant than the other.—Chatterton's "Miscellanies in Prose and Verse" were published in 1778. An edition of his works, with his life, was prepared by Southey and Cottle in 1803. There have been several editions and biographies, the latest published in London, 1872.—See "Chatterton, a Biographical Study," by Daniel Wilson (London, 1870).

CHATTOOGA. I. Or *Chatuga*, one of the head branches of the Savannah river, rises near the S. frontier of North Carolina, and flows S. W. about 40 m. along the boundary between South Carolina and Georgia. II. A river of N. W. Georgia, rises in Walker co., and flows S. S. W. about 55 m. through Chattooga co. to the Coosa in Cherokee co., Ala.

CHATTOOGA, a N. W. county of Georgia, bordering on Alabama, and intersected by the Chattooga river; area, 360 sq. m.; pop. in 1870, 6,902, of whom 1,503 were colored. The surface is diversified by valleys and mountains connected with the Blue Ridge. The principal summits are Taylor's ridge, John's mountain, and Dirtseller mountain. Limestone, marble, iron, and lead are abundant. The chief productions in 1870 were 58,232 bushels of wheat, 145,403 of Indian corn,

17,802 of oats, and 901 bales of cotton. There were 803 horses, 1,094 milch cows, 2,110 other cattle, 3,623 sheep, and 8,732 swine. Capital, Summerville.

CHAUCER, Geoffrey, an English poet, born probably in London in 1328, died there, Oct. 25, 1400. Sharon Turner, however, suggests that the year 1340 is more likely to have been that in which Chaucer was born than 1328. The principal events of his life are tinged with uncertainty. Leland represents him to have studied both at Cambridge and at Oxford, and at the latter place to have diligently frequented the public schools and disputations, and even there to have affected the opinions of Wycliffe in religion. Tyrwhitt doubts his having studied at either university. He appears to have been entered at the Inner Temple; but the evidence of this is stated to rest simply upon the record of one Geoffrey Chaucer having been fined two shillings for beating a Franciscan friar in Fleet street. Leland states that he engaged in the practice of the law, while Mr. Tyrwhitt contests the point. He had undoubtedly early ingratiated himself into the friendship of persons of distinction, was a page to King Edward III., and was rewarded by that monarch in 1367 with an annuity of 20 marks, equivalent to about £200 of present money. These facts are verified by public documents appended to the biography by Godwin. He appears afterward to have become gentleman of the bedchamber to the king, and in 1370 was sent abroad as a royal envoy. Two years later he was sent to Genoa, with two other ambassadors, to negotiate for ships for a naval force; and it appears that his success was so great as to win many proofs of royal favor. He was made on his return partial comptroller of the customs of London, and was allowed to receive daily from the butler of England a pitcher of wine. In 1377 he is referred to by Froissart as an English envoy employed on the continent on secret service. The object of this mission, according to the same authority, was a treaty of peace and a marriage of the king's grandson, afterward Richard II., with the French princess Mary. Neither of these aims was accomplished, and Edward dying in June of the same year (1377), there was an end of this great patronage. In the mean time the poet and diplomatist had married one of the maids of honor to the queen, Philippa Rouet, whose sister, the widow of Sir Hugh Swinford, became first the mistress and then the wife of John of Gaunt, "time-honored Lancaster." This high connection obtained for Chaucer a continuation of royal favor under the new king, Richard II., and he was commissioned upon several urgent matters in various parts of the kingdom. For the safe prosecution of these unknown errands, the king granted him a species of safe conduct, or protection from arrest or injury. After Richard's deposition in 1399, all his donations to Chaucer were immediately

confirmed by Henry IV., who, being the son of the duke of Lancaster, stood somewhat in the light of nephew to the poet. Toward the close of 1399 we find Chaucer taking a lease of a residence in the garden of the priory of Westminster. The foregoing facts rest upon official documents appended to the life of Chaucer by Godwin. Other events, less authentic, are gleaned from passages in his works. As an adherent of the duke of Lancaster, he embraced the opinions of Wycliffe, and formed a close connection with that divine. Persecution and reverses followed in consequence of this. Godwin refers his personal misfortunes to his support of a Wycliffian candidate for the mayoralty of London, John of Northampton, who was arrested and imprisoned. Chaucer escaped to the continent, where, during some years in France and Denmark, he wrote many of his books. He suffered much privation meanwhile from the faithlessness of agents who appropriated his income, and was at length induced to return secretly in hopes of recovering his dues. He was discovered and arrested, but at length obtained pardon and liberty by disclosing the designs of the men with whom he had been associated. This drew upon him a flood of obloquy, which he appears to have attempted to parry by offering an appeal to arms. He was certainly thereafter received again into royal favor; and expressions of remorse are discoverable in his subsequent writings, although somewhat vaguely. Soon after these events he removed from the turmoil and intrigues of public life into literary retirement. His first retreat was at Woodstock, and finally, upon the death of the duke of Lancaster, at Donnington castle, where an aged and favorite oak tree, under whose branches the poet often meditated, long afterward bore his name. It was here that he wrote his most remarkable and latest work, the "Canterbury Tales." Their general plan is of a company of pilgrims on their way to Canterbury assembling at an inn, and agreeing each to tell a tale in going and returning; he who should tell the best tale to be treated by the others with a supper at the inn. In this work Chaucer is considered to have improved upon his model, the "Decameron" of Boccaccio, especially in variety of character and delicacy of discrimination; but the introduction or introductory machinery is contrived with less felicity. This work, in verse, begun in declining years, was left incomplete. Chaucer's command over the language of his day, and his exhibition of existing character and passing incident, constitute his attraction. His early works bear the stamp of the corrupt tastes of his age, but are everywhere remarkable for delineation of character. The "Romaunt of the Rose" is professedly a translation of the French *Roman de la rose*. "Troilus and Cresseide," his second poetical essay, taken chiefly from Boccaccio, contains passages of much pathos and beauty. The story

of "Queen Annelida and False Arcite" was acknowledged by the author to have been taken from *Stace* and *Corinne*. The opening is from Statius, but *Corinne* has not, we believe, been identified. The opening of the "Assembly of Fowles" is founded upon the *Somnium Scipionis* of Cicero. The "House of Fame" has been supposed to have been originally a lay of Provence; but this idea has been combated by Tyrwhitt, whose studies of Chaucer were profound. This commentator suggests a doubt of the "Flower and the Leaf" being from the pen of Chaucer, which Dryden modernized without expressing a suspicion of its authenticity. It was printed for the first time in Speght's edition of Chaucer in 1598. The prose works are a translation of Boëthius, the "Treatise on the Astrolabe," and the "Testament of Love." The translation of Boëthius, and occasional quotations from Juvenal and Seneca, prove that he retained an acquaintance with the Roman classics. It is impossible to ascertain the exact chronology of his works. He left by his wife two sons, Thomas and Lewis, the first of whom was speaker of the house of commons in the reign of Henry IV., and was ambassador to France and Burgundy; and a daughter, Alice, who married the duke of Suffolk. He was buried in Westminster abbey, being the first poet there interred. A century and a half after his death a monument was erected there to his memory by Nicholas Brigham.—The principal biographers and editors of Chaucer are Speght, Leland, Tyrwhitt (5 vols. 8vo, London, 1798), and Godwin (2 vols. 4to, London, 1803). Some of his poems have been modernized by Dryden, Pope, Wordsworth, Leigh Hunt, R. H. Horne, and Elizabeth Barrett Browning. In C. C. Clarke's "Riches of Chaucer" (2 vols., 1835) the best pieces are given with only the spelling modernized. The Chaucer society published in 1868 an edition of the "Canterbury Tales," giving the six principal texts.

CHAUCI, one of the most powerful tribes of ancient Germany. They dwelt between the rivers Ems and Elbe, being divided by the Weser into *Majores* on the west and *Minores* on the east. According to Tacitus, their country was extensive and thickly peopled. They were distinguished for their love of justice and of peace, being powerful but unambitious, never provoking war, but always ready to repel aggression. They were allies of the Romans in the war of Germanicus against the Cherusci, but subsequently their enemies in the reigns of Claudius and Nero. They are last mentioned in the 3d century as devastating Gaul. They were finally merged in the general name of Saxons.

CHAUDES-AIGUES (Lat. *Aquæ Calentes*), a watering place of Auvergne, France, in the department of Cantal, 26 m. E. by S. of Aurillac; pop. in 1866, 1,948. It is situated in a narrow and picturesque gorge, and derives its name from some hot springs in its vicinity,

which are extensively used for baths, for washing fleeces, and for warming the houses during the winter. The so-called mineral springs, four in number, consist almost entirely of pure water of a high temperature. The annual attendance of visitors is about 500. The spring called *Source du Par*, one of the hottest springs in Europe, has a temperature of 177°; the others vary from 135° to 162°. Woollen goods and hosiery are manufactured in the town.

CHAUDET. I. Antoine Denis, a French artist, born in Paris, March 31, 1763, died April 19, 1810. His statue of *Œdipus*, exhibited in 1801, established his reputation as a sculptor. Among his other works are "Paul and Virginia," "Sensibility," "Surprise," the silver statue of "Peace" in the Tuileries, the "Napoleon" which previous to 1815 surmounted the column in the Place Vendôme, and the bass relief of "Painting, Sculpture, and Architecture," in the Musée Napoléon. He excelled also as a painter and designer, and illustrated Didot's edition of Racine and other works. He was professor of sculpture, and contributed many written articles to the dictionary of the academy. His works tended to modify the classicism which prevailed in the French schools of art in the beginning of the present century.

II. Jeanne Elisabeth Gabion, wife of the preceding, born in 1767, died about 1830. A pupil of her husband, she painted a "Child teaching a Dog to read," and many little pictures of the kind, and excelled also as a portrait painter.

CHAUDIÈRE, a river of the province of Quebec, Canada, rises near the boundary line between Canada and the United States, and flows into the St. Lawrence about 7 m. above Que-

bec. Its length is about 120 m., and its usual width is from 400 to 600 yards; but it is often contracted by rocks jutting from either side, which occasion violent rapids, and render the stream unnavigable. About 2½ m. from its mouth are the falls of the Chaudière, where

the water, first contracted by salient points of rock, is then thrown over a precipice from a height of 100 ft. An iron bridge for the Grand Trunk railway is thrown across it near its mouth, where the banks are high. The scenery on the banks of this river is very picturesque. —In the Ottawa river, at the city of that name, is another cataract called Chaudière falls. (See OTTAWA.)

CHAUDON. I. Dom Louis Maieul, a French author, born at Valensolle, May 20, 1737, died at Mezin, May 23, 1817. He studied in the colleges of Marseilles and Avignon, and entered the order of Benedictines. His principal work, the *Nouveau dictionnaire historique* (Avignon, 1766), was designed to be equally removed from the prolixity of Moréri and the dryness of Ladvocat. It was the basis of the subsequent and distinct work of Feller. He wrote *Leçons d'histoire et de chronologie*, and *Dictionnaire anti-philosophique*; and for other works which he composed in defence of religion he received honorable briefs from Clement XIII. and Pius VI. **II. Esprit Joseph**, a French author, brother of the preceding, born at Valensolle in 1738, died in 1800. After teaching the humanities in several colleges of the Oratorians, he published in 1772, at Avignon, a valuable bibliographical work, entitled *Bibliothèque d'un homme de goût*, many materials of which were furnished by his brother. In 1778 he published in Paris a *Dictionnaire interprète-manuel des noms latins de la géographie ancienne et moderne*.

CHAUFFEPIÉ, Jacques Georges de, a Protestant divine of Holland, of French origin, born in Leeuwarden, Nov. 9, 1702, died in Amsterdam, July 3, 1786. He is principally known as the author of the *Nouveau dictionnaire historique et critique, pour servir de supplément ou de continuation du Dictionnaire historique et critique de M. Bayle* (4 vols. folio, Amsterdam, 1750-'56).

CHAUFFEURS, or **Garrotteurs**, a class of brigands during the reign of terror in France. Their headquarters were first in the forest of Orgères, near the city of Chartres, and afterward they infested other parts of the country in bands, organized under the leadership of Johann Bückler, sur-

Chaudière Falls.

named Schinderhannes, till 1803, when the measures adopted under the consulate put a stop to their depredations. They garrotted their victims, and tortured and burned (*chauffé*) their feet to make them disgorge their treasures. While engaged in burglaries they

named Schinderhannes, till 1803, when the measures adopted under the consulate put a stop to their depredations. They garrotted their victims, and tortured and burned (*chauffé*) their feet to make them disgorge their treasures. While engaged in burglaries they

put a black veil over their faces, or blackened them with soot.

CHAULIAC, Cauliac, or Chaulien, Gui de, a French surgeon of the 14th century, studied at Montpellier and Bologna, practised his profession in Lyons, and was afterward employed by three popes of Avignon, Clement VI., Innocent VI., and Urban V. He is the author of a remarkable treatise on surgery, entitled *Inventarium, sive Collectorium Partis Chirurgicæ Medicinæ*, which was translated into French by Laurent Joubert, under the title of *Grande chirurgie*, and accompanied with annotations and an index by his son Isaac Joubert (8vo, Lyons, 1592). This was the first work of importance on the principles and practice of surgery published in Europe after the middle ages, and during two centuries it was considered the classical work on that branch of science. It is even now esteemed for its simplicity and clearness on many points. Plasters and poultices, ointments and embrocations were almost the only resources of surgical practice in western Europe before the time of Chauliac. He reestablished the practice of such operations as had been described and performed by the ancient Greeks and the Arabian surgeons, invented several new instruments, and undertook certain operations on the crystalline lens, for the restoration of sight, in cases of cataract. He laid the foundations of the modern principles and practice of surgery; and though his works are tinged with astrological notions, they are replete with practical instruction. He also wrote a description of the plague which visited France in 1348, and by which he was himself attacked.

CHAULIEU, Guillaume Amfrye de, a French poet, born at Fontenay in 1639, died in Paris, June 27, 1720. By his associates he was called the Anacreon of France, and by Voltaire the first of neglected poets. The best edition of his works appeared in 1774, in 2 vols. 8vo. His *Lettres inédites* were published in 1850.

CHAUMETTE, Pierre Gaspard, a French revolutionist, born at Nevers, May 24, 1763, guillotined in Paris, April 13, 1794. He was the son of a shoemaker, but ran away from home, and became cabin boy and steersman on a river vessel. In 1789 he was a lawyer's clerk at Paris, and became a journalist and popular revolutionary orator. He was engaged in the insurrection of Aug. 10, 1792, and in September was appointed procureur of the commune, in which capacity he vindictively prosecuted Louis XVI. and his family. He got up those fêtes in which everything sacred and decent was profaned in the name of reason. He took part in the movement of May 31, 1793, which overthrew the Girondists, and later he joined Hébert and Anacharsis Clootz in a conspiracy against the Mountain, as too lenient toward the aristocrats. His atheistic speeches and popular excesses alarmed even Danton and Robespierre, and the conspiracy being discovered, its authors were arrested March 13, 1794, and Hébert and Clootz were executed.

Chaumette, whose popularity made him formidable, was not imprisoned at that time, but some days after was brought before the tribunal, condemned, and executed. His memory was execrated by all parties.

CHAUMONOT, or Chaumonnot, Pierre Marie Joseph, a French missionary, born near Châtillon-sur-Seine in 1611, died at Lorette, near Quebec, Canada, Feb. 21, 1693. In early life he entered the society of Jesus in Rome, and was sent at his own request as a missionary to the North American Indians. In company with Père Poncet he landed at Quebec in 1639, and devoted himself to the instruction of the Hurons, Petuns, and Neutrals. He resided among these tribes until the Hurons were dispersed by the Iroquois, when he accompanied a small body of fugitives to Quebec in 1650. In the following year he removed with the Hurons to Isle Orleans, where a Christian settlement was formed. In 1655 he visited the Onondagas, but returned to his flock in 1658, and was instrumental in founding the mission of Notre Dame de Foye, five miles from Quebec. This establishment was removed to Lorette in 1693, and soon after Père Chaumonot closed his career after more than half a century of hardships. He left an excellent grammar of the Huron language, published by the literary and historical society of Quebec in 1835; a list of radical and derivative words, a catechism, and a series of instructions, all in the same language, and a memoir of his own life addressed to his superior. These last have not been published.

CHAUMONT, or Chaumont-en-Bassigny, a town of France, capital of the department of Haute-Marne, about 1½ m. from the confluence of the Marne and the Suize, 133 m. S. E. of Paris; pop. in 1866, 8,285. It has a departmental college and a public library of 37,000 volumes. There is a triumphal arch begun by Napoleon I. and finished by Louis XVIII. The manufacture of iron wares forms the leading indus-

Castle of Chaumont.

try; but there are manufactories of woollens, linen and cotton yarn, and a considerable trade in iron wares, grain, and skins. The allied powers concluded a treaty here against Napo-

leon, March 1, 1814, which afterward became the basis of the holy alliance.

CHAUNCEY, Isaac, an American naval officer, born at Black Rock, Conn., Feb. 20, 1772, died in Washington, Jan. 27, 1840. He commenced his career in the merchant service, in which he became distinguished for seamanship, enterprise, and energy. He entered the navy as lieutenant in 1799, and early in 1802 was appointed acting captain of the frigate Chesapeake, of 38 guns, the flag ship of a squadron ordered to the Mediterranean, under the command of Commodore Valentine Morris, to operate against Tripoli. He served actively during a large part of the war with Tripoli, and also in the squadrons of Commodores Preble and Rodgers, in command of the John Adams, of 28 guns. In the brilliant operations before Tripoli in 1804 he bore a distinguished part. In that year the grade of master commandant (afterward commander) was reestablished in the navy, and he was one of eight lieutenants promoted to it. In April, 1806, he was advanced to the rank of captain. In the war of 1812 the naval superiority on the lakes became an object of high importance, and Commodore Chauncey, then in command of the navy yard at New York, was appointed to command on all the lakes except Champlain. On Oct. 6, 1812, he arrived at Sackett's Harbor, and entered upon his duties. In 1813 he coöperated with the land forces in the capture of York (now Toronto), and also of Fort George, which led to the evacuation of the British of the whole Niagara frontier. During the summer of that year he was engaged in watching the enemy and superintending the ship building at Sackett's Harbor. On Sept. 27 Chauncey succeeded in engaging the British squadron in York bay, which resulted in the retreat and pursuit of the latter. On Oct. 5 he captured five of the enemy's vessels with part of a British foreign regiment. On Aug. 9, 1814, he appeared off Kingston and blockaded the squadron of Sir James Yeo for six weeks, and held the command of the lake until the close of navigation. Peace was concluded before operations could be commenced in the ensuing spring. During his subsequent career he commanded the navy yard at New York at different times; also the squadron in the Mediterranean, and with William Shaler, consul, negotiated a treaty with Algiers. He also served upon the board of navy commissioners, to the presidency of which he was appointed in June, 1833, and held this position at the time of his death.

CHAUNY. I. Charles, second president of Harvard college, born in Hertfordshire, England, in 1592, died Feb. 19, 1672. Educated at Westminster and Cambridge, he made the acquaintance of Archbishop Usher, and was appointed professor of Hebrew, and afterward of Greek, at Cambridge. Leaving that position soon after, he took the vicarage of Ware, Hertfordshire. His stern Puritanism involved

him in a difficulty with the ecclesiastical judicatories on the publication of the "Book of Sports," and the introduction of railing out the communion table. He was imprisoned and fined for his denunciation of these acts of the church, and recanted, but soon repented of his recantation. He therefore determined to embark for New England, where he arrived June 1, 1638. Here he was reordained, and for three years remained in Plymouth as assistant pastor, and then became pastor at Scituate, Mass. There he remained until the change in the ecclesiastical polity of England, when he resolved to return to his vicarage in Ware, which had invited him home. But the first president of Harvard college, Mr. Dunster, having resigned, the office was offered to Mr. Chauncey, accepted (1654), and held until his death. He published sermons (1655-'9), and *Antisynodalia Americana* (1662). **II. Charles**, an American clergyman, great-grandson of the preceding, born Jan. 1, 1705, died Feb. 10, 1787. He graduated at Harvard college in 1721, and was ordained pastor of the first church in Boston in 1727, as the colleague of Mr. Foxcroft. He was a copious writer, and published many works; among the rest a "Complete View of the Episcopacy," being the substance of a discussion with Dr. Chandler of New Jersey; "Seasonable Thoughts on the State of Religion in New England;" "Discourse on Enthusiasm;" "Remarks on the Bishop of Llandaff's Sermon;" "Mystery hid from Ages, or the Salvation of all Men;" and "The Benevolence of the Deity." He was for 60 years the minister of one parish. **III. Charles**, an American jurist, born at Durham, Conn., June 11, 1747, died in New Haven, April 28, 1823. He was admitted to the bar in 1768, and removed to New Haven. He was made attorney for the state of Connecticut in 1776, and judge of the superior court in 1789. In 1793 he retired to private life. He was not college bred, but was a good scholar and a clear-headed man. He taught jurisprudence for 40 years. **IV. Charles**, an American lawyer, son of the preceding, born in New Haven, Aug. 17, 1777, died Aug. 30, 1849. He removed to Philadelphia after completing his studies, and was admitted to the bar in 1799, where he soon held a divided honor of precedence with John Sargeant and Horace Binney. The various honors of state and judiciary which were tendered to him he declined. He was a man of great erudition, of winning manners, and of unimpeachable integrity.

CHAUNY, a town of France, in the department of Aisne, partly built on an island in the river Oise, which is here connected with the canal of St. Quentin, situated on the Northern railway (from Paris to Cologne), 66 m. N. E. of Paris; pop. in 1866, 9,080. The town derives its principal commercial importance from the glass works of St. Gobain, which are about 7 m. distant. It has manufactories of cotton fabrics, soda, and sulphuric and muriatic acids.

CHAUS. See LYNX.

CHAUSSARD, Pierre Jean Baptiste, a French author, born in Paris in 1766, died there in 1823. He had achieved considerable reputation as a jurist and scholar at the outbreak of the revolution, in which he took an active part under the name of Publicola. He was appointed commissioner in Belgium, but his arbitrary proceedings led to his speedy return to Paris. For a short time he held several local offices, and from 1803 to 1815 he was professor in various towns. The restoration depriving him of employment, he continued to write on a great variety of subjects. The best of his works is *Épître sur quelques genres dont Boileau n'a point fait mention dans son Art poétique* (1811), of which he published in 1817 a poetical version under the title of *Poétique secondaire*, &c. His most popular ode was *L'Industrie et les arts*. His works on Greek courtesans and on Heliogabalus have been censured on account of their superficial and licentious character; but his works on art, education, &c., enjoy a better reputation.

CHAUTAUQUA, the westernmost county of New York, bounded N. W. by Lake Erie, and W. and S. by Pennsylvania; area, about 1,000 sq. m.; pop. in 1870, 59,327. It is well supplied with water power, and drained by Conewango creek, its tributaries, and several other smaller streams. Chautauqua ridge passes through the county. Between this ridge and the lake, a distance of from 3 to 10 m., the surface is nearly level, and the soil very fertile. The country around the streams is also extremely productive. Iron ore, marble, and sulphur springs have been found in several places. There are springs emitting carburetted hydrogen, the gas from some of which has been successfully employed in lighting houses. The Erie, the Atlantic and Great Western, the Lake Shore, the Buffalo, Corry, and Pittsburgh, and the Dunkirk, Warren, and Pittsburgh railroads traverse the county. The chief productions in 1870 were 148,849 bushels of wheat, 254,110 of Indian corn, 755,451 of oats, 43,927 of barley, 314,873 of potatoes, 162,272 tons of hay, 773,830 lbs. of cheese, 5,049,037 of butter, 193,891 of wool, and 342,732 of maple sugar. There were 13,244 horses, 46,990 milch cows, 20,511 other cattle, 40,404 sheep, and 13,429 swine. There were 9 manufactories of agricultural implements, 53 of carriages, 13 of cheese, 18 of furniture, 8 of machinery, 2 of woollen goods, 1 railroad repair shop, 9 planing mills, 50 saw mills, 21 tanneries, 26 flour mills, 1 manufactory of cars, 1 of rectified coal oil, 1 of edged tools and axes, 1 of hardware, 2 of iron castings, 1 of pianos, 2 of paper, 23 of saddlery and harness, 5 breweries, and 9 establishments for currying leather. Capital, Mayville.

CHAUTAUQUA LAKE, a beautiful sheet of water in the centre of Chautauqua co., N. Y., 18 m. long and from 1 to 3 m. wide. It lies 1,290 ft. above the Atlantic and 730 ft. above

Lake Erie. Its outlet, which is navigable by small boats, opens into Alleghany river. The name is a corruption of an Indian phrase signifying a "foggy place," and was given in consequence of the mists which frequently rise from the surface of the lake.

CHAUVEAU, Pierre J. O., a Canadian statesman and author, born at Quebec, May 30, 1820. He received his education at the seminary in that city, and studied law. He first attracted attention as a writer in *Le Canadien* from 1838 to 1841. In 1844 he was elected to the legislature for the county of Quebec. He was solicitor general in 1851, and provincial secretary in 1853, holding the latter office till 1855, when he was appointed superintendent of education for Lower Canada. Under his administration of the school system normal schools were established, and the cause of education advanced. After the confederation was organized, he was first minister of the government of Quebec from 1867 to the beginning of 1873, when he became speaker of the senate of Canada. He has considerable literary reputation in Canada. His principal work is "Charles Guérin," a novel published in 1853, which gives a graphic picture of French-Canadian life and society. It was the first French-Canadian novel ever published.

CHAUVEAU-LAGARDE, Claude François, a French advocate, born at Chartres about 1760, died in Paris in February, 1841. He acted as advocate for Miranda, Brissot, Charlotte Corday, Marie Antoinette, and Madame Élisabeth. Soon after the condemnation of the queen he was arrested, and was not liberated till after the fall of Robespierre. He was advocate to the council of state under Napoleon, and was appointed to congratulate Louis XVIII. on his entrance into the capital. After the second restoration he devoted himself to the defence of the proscribed. Besides numerous speeches and political pamphlets, he published narratives of the trials of Marie Antoinette and Madame Élisabeth.

CHAUVENET, William, an American mathematician and astronomer, born in Milford, Penn., May 24, 1819, died at St. Paul, Minn., Dec. 13, 1870. He graduated with high honors in 1840 at Yale college, where his mathematical talents had already found an early recognition. He immediately became associated with Alexander Dallas Bache, his life-long friend and master in science, in delicate and important meteorological and magnetic observations at Girard college, Philadelphia. This connection continued till his appointment in 1841 to a professorship of mathematics in the navy. He promoted the establishment of the naval academy at Annapolis, the change in the system of educating naval officers, and the institution of the naval academy observatory, of which last he was at once appointed director. In 1859 he was called to the chair of mathematics and astronomy at Yale college and at the Washington university of St. Louis, Mo. Choosing the latter, he continued there till

1868, when ill health obliged him to resign his chair, to the duties of which had been added the chancellorship of the university. Many of his contributions to scientific knowledge were of great practical value, such as his methods of determining the longitude at sea, of rating chronometers, of great circle sailing charts, &c. His "Treatise on Practical and Spherical Trigonometry" (2 vols. 8vo, Philadelphia, 1863) was declared by Prof. Bond of Harvard college to be "the most thorough and complete which had appeared in any country or language." His other works include "The Binomial Theorem Theory of Exponents and of Logarithms" (1843); "Plane and Spherical Astronomy" (1850), a work following the methods of Gauss and Bessel; and "On Elementary Geometry" (1870).

CHAUVINISM, a term used in France denoting a fanatical adherence to an effete leadership or obsolete national aspirations. At the time of the disbandment of Napoleon's guards in 1815, many soldiers attracted attention by the coincidence of all bearing the name of Chauvin, and of all extolling the fallen emperor. Nicolas Chauvin, a brave but foolish grenadier, created especial merriment by his grotesque displays of attachment to his former chief, which were caricatured on the stage and in print. This is the generally accepted origin of the term, although some authorities seek to trace it to the French *chauve* (bald), and to connect with it an idea of senility and dotage.

CHAUX-DE-FONDS, La, a borough of Switzerland, in the canton and 9 m. N. W. of Neuchâtel; pop. in 1870, 19,930. It is a large scattered town, resembling an assemblage of farm houses and hamlets, a garden plot surrounding every cottage. It is situated in a rugged narrow valley of the Jura, at an elevation of more than 3,000 ft. above the sea. Great prosperity prevails among the inhabitants, mainly owing to the manufacture of clocks and watches, of which this place and the neighboring town of Locle are the chief seats. The number of persons employed in this manufacture in the vicinity is about 12,000, who produce annually 800,000 gold and silver watches, worth about \$7,000,000. In 1774 the number produced was about 300. The manufacture is not carried on in factories, but in the separate dwellings of the workmen, each of whom usually makes only one particular piece, leaving even the finishing of it to others. The inhabitants excel also in carving, jewelry, and enamelling, and in various other arts of the same kind, and in the manufacture of chemical, mathematical, and surgical instruments, and of lace. The painter Léopold Robert and the mechanicians Droz (father and son) were born at La Chaux-de-Fonds. There are here two subterranean mills, turned by the stream before it sinks into a deep chasm underground, the rocks having been blasted out to give space for the mills. The Doubs, which flows on the neighboring French frontier, trav-

erses a fissure in the limestone, and a few miles N. of Chaux-de-Fonds has a fall of 80 ft., below which for nearly 6 m. it runs between cliffs 800 or 1,000 ft. high.

CHAVÉE, Honoré Joseph, a Belgian philologist, born in Namur, June 3, 1815. He was ordained in 1838, published in 1841 *Essai d'étymologie philosophique*, &c., and went in 1844 to Paris, where he became professor at the collège Stanislas and the Athénée. About 1855 he established there a school of comparative philology, and in 1867 the *Revue de Linguistique*. He left the priesthood after the publication of his *Lexicologie indo-européenne*, &c. (Paris, 1849), in which he supports the theory of the original plurality of races and languages. He also wrote *Moïse et les langues* (1855), and *Les langues et les races* (1862).

CHAVES (anc. *Aqua Flavia*), a town of Portugal, in the province of Tras-os-Montes, 35 m. W. S. W. of Braganza; pop. about 7,000. The fortifications which once defended it are now in ruins. It is situated on the Tamega river, here crossed by a Roman bridge of 18 arches, and has hot saline springs and baths. It has an interesting church, the burial place of Afonso, duke of Braganza. On March 12, 1809, after a violent conflict, Soult obtained possession of the place; and after the defeat of the Cartistas (Sept. 18, 1837), the convention of Chaves was signed here.

CHAVES, Manoel de Silveira Pinto de Fonseca, marquis of, and count of Amarante, a Portuguese general and statesman, born at Villa Real, died in Lisbon, March 7, 1830. He was opposed to the Portuguese liberals, and on the arrival of the duke of Angoulême in Spain in 1823, he raised the standard of revolution in Portugal in favor of Dom Miguel and absolutism. He was proclaimed a traitor, and being defeated by Gen. Riego, he retired into Spain. There he continued to carry on his intrigues, and on the death of John VI. in 1826 he returned to Lisbon. He performed a conspicuous part in the disturbances which followed, and underwent the vicissitudes of exile and return, always retreating after his numerous defeats over the Spanish frontier. To put an end to the intrigues of the Portuguese refugees with the Spanish court, the English, who were favorable to the constitutional cause in Portugal, declared that any participation in the struggle by the Spanish authorities would be regarded as a *casus belli*. To avoid this risk, Chaves was sent away from the frontier. Subsequently, after Dom Miguel had been installed as regent, February, 1828, Chaves returned to Portugal and assisted the usurper in seizing the crown for himself. This accomplished, he was neglected, and soon afterward retired from court, disgusted with the ingratitude of Dom Miguel; and the latter part of his life was spent in gloom and obscurity, still more saddened by partial insanity.

CHAZAL, Antoine, a French painter and designer, born in Paris in 1793, died there in

1854. He devoted himself especially to the painting of flowers and fruit, and designed and engraved many plates for works on natural history, anatomy, &c.; among which are the *Traité des accouchements* by Maygrier, the *Ovologie humaine* by Velpeau, the *Embryogénie comparée* by Coste, the *Anatomie pathologique* by Cruveilhier, and the *Flore des Canaries* by Webb. He made also 40 studies of medicinal plants in aquarelle for the medical school in Lexington, Kentucky. In 1835 he was named professor of design in the museum of natural history in Paris. He painted for the museum many of the wild animals after nature, and some genre pictures and portraits, among the latter one of Washington.—His son, CHARLES CAMILLE, born in Paris in 1826, is also a painter of some note.

CHEATHAM, a N. W. county of Tennessee, intersected by Cumberland river; area, 350 sq. m.; pop. in 1870, 6,678, of whom 1,470 were colored. The surface is undulating. It is traversed by the Nashville and Northwestern railroad. The chief productions in 1870 were 19,572 bushels of wheat, 274,052 of Indian corn, 44,585 of oats, 62 bales of cotton, and 419,265 lbs. of tobacco. There were 1,450 horses, 1,529 milch cows, 2,732 other cattle, 4,825 sheep, and 14,980 swine. There were 12 saw mills and a manufactory of gunpowder. Capital, Ashland City.

CHEAT RIVER, in West Virginia, is formed by the union of the Laurel, Glade, Shaver's and Dry forks, which rise among the Alleghany mountains, near the N. border of Pocahontas co., and meet in Tucker co. It flows N. and N. W. through a hilly country, well adapted to grazing, and rich in coal and iron, and falls into the Monongahela at the S. W. extremity of Fayette co., Pa. It furnishes fine water power, and is navigable 40 m. above Rowlesburg, but not in its lower course.

CHEBOYGAN, an extreme N. county of Michigan, bordering on the straits of Mackinaw and Lake Huron; area, about 500 sq. m.; pop. in 1870, 2,196. It is drained by Black and Cheboygan rivers, and contains several lakes. The chief productions in 1870 were 1,070 bushels of wheat, 8,285 of oats, 8,484 of potatoes, 1,267 of peas and beans, and 349 tons of hay. The total value of live stock was \$20,585. There were 2 ship-building establishments and 6 saw mills. Capital, Duncan.

CHECKERBERRY. See PARTRIDGE BERRY, and WINTERGREEN.

CHÉDOTELO, a Norman navigator, the dates of whose birth and death are unknown. On account of his thorough knowledge of the coasts of New France he was selected in 1598 to guide thither the expedition of the marquis de la Roche. On his arrival at Sable island he landed 50 men, the most of whom were from the French prisons, and departed to examine the coast of Acadia. He was prevented by stress of weather from landing on his return, and the men remained on the island for seven years, leading the life of savages. In 1605 the parliament of

Rouen sent him for them, and he recovered 12, all that remained. Arrived in France in a state of destitution, they were presented to Henry IV., who gave to each 50 crowns and a pardon.

CHEDUBA, an island in the bay of Bengal, belonging to the district of Ramree; area, about 400 sq. m.; pop. about 6,000. It was first occupied by the English in 1824. The channel between it and the mainland is navigable for small vessels. Copper, iron, and silver have been found in this island, and it affords indications of extinct volcanoes. It produces petroleum, rice, tobacco, pepper, sugar, cotton, hemp, and indigo.

CHEE-FOO, a town of China, and one of the last ports opened to foreign trade, in the province of Shantung, lat. 37° 30' N., lon. 121° 28' E.; pop. variously estimated from 25,000 to 80,000. The chief trade consists in tea pressed into cakes for the Russian market. A species of large delicious grape is cultivated here, though no wine is made.

CHEESE, the curd of milk, separated from the whey and compressed into a solid mass. It consists of the caseine and butter and a portion of the water and saline constituents of the milk, and whatever salt may be added in the manufacture. The proportion of butter is subject to the greatest variation, depending as it does upon the richness of the milk, and the quantity which may have been abstracted by skimming, or which, as in Stilton cheese, may have been added by taking cream from other milk. Caseine (from Lat. *caseus*, cheese) is the coagulable constituent, and belongs to the group of albuminoids or proteine compounds which compose the principal part of the nitrogenous material of plants and animals. It is found not only in milk, but in other animal fluids. According to Berzelius, Braconnot, and others, it has two modifications, one soluble and the other insoluble in water; but later investigations have shown that its solubility depends upon its combination with a portion of alkali, and as found in milk it may be regarded as a natural alkali-albumen, similar to that found in the blood. As analyzed by Scherer, it consists, after deducting the ash, of carbon 52·7, hydrogen, 7·2, and nitrogen 15·6. Walther and Verdeil found one part of sulphur. Mulder found 6 per cent. of phosphate of calcium, which is precipitated by adding an acid. It is concluded, therefore, that pure caseine can only exist in a soluble condition, and that when precipitated by coagulation it is deprived of a part of its constituents. The spontaneous coagulation of milk has been generally regarded as caused by the action upon caseine of lactic acid which has been formed by the fermentation of lactose or sugar of milk; but late investigations have created some doubt as to the extent to which lactic acid alone acts as the agent. Organic bodies have been found in new milk which are capable of being developed into a ferment, to which some have ascribed the power of causing caseine to coagulate. How far this ferment may act in

conjunction with lactic acid, or the extent of its agency in generating lactic acid, has not been determined. Moist caseine exposed to the air soon putrefies, yielding sulphide and carbonate of ammonia, and an oily body having a disagreeable smell, together with butyric and valeric acids, the undecomposed caseine dissolving in the ammonia which is formed. Caseine plays an important part in the making of cheese, although as a constituent its quantity is often less than that of butter. An analysis by Völcker of an average sample of good milk gave :

Water	87.30
Butter	3.75
Caseine	3.31
Milk sugar and extractive matter	4.86
Mineral matters (ash)	0.75
	100.00

The cheese which was made from this milk had the following composition :

Water	37.85
Butter	23.91
Caseine	25.00
Extractive matter, lactic acid, &c.	4.91
Mineral matter containing common salt	3.33
	100.00

—In cheese making, the coagulation of the milk may be effected in either of two ways: by adding an acid, which is done in Holland, or by subjecting the caseine to a peculiar fermentation induced by the action of rennet, which is the usual mode. Rennet is usually prepared from the fourth stomach of the calf, by salting and drying. The stomach should not be washed, but turned and carefully wiped with a cloth, sprinkled with salt, and dried at a moderate temperature in the open air, stretched upon a small hoop or forked stick. It is prepared for use by steeping it either in whey or brine. Whey is preferred for the reason that it more readily assists in inducing lactic acid fermentation; but it should first be freed from the albuminous matter which it contains, by boiling and straining. The steeping occupies about a week, during which time the rennets should be squeezed and rubbed to extract the active principle. A wooden vessel should never be used, as it is almost certain to impart putrefactive properties to the rennet which are injurious to the cheese, but the steeping should be done in earthen jars. The English method is to steep the rennets in a brine strong enough to bear an egg, adding six rennets, one sliced lemon, and an ounce of saltpetre to two gallons of brine. The brine liquor is usually prepared one or two months before it is used, as it is believed that this age improves its coagulating qualities. The theory of the action of rennet is not yet considered to be well established. Liebig, although admitting the necessity of the presence of a ferment to initiate by a catalytic force the fermentation of milk sugar and its conversion into lactic acid, rejects the theory of Pasteur that the process is the result of the constant development of a minute fungus

which has been called *micrococcus*. W. Hallier, however, following Pasteur, has found that newly made cheese contains numerous ferment nuclei, which he considers as a kind of putrefactive yeast. According to his investigations, these nuclei are developed, as are the nuclei of beer yeast, from spores of *penicillium*, differing from them only on account of the difference in the fluid which affords them nourishment. In beer the *penicillium*, according to Hallier, is developed into *cryptococcus*, while in fresh milk it is converted into *micrococcus*, and when the milk becomes sour into *arthrococcus*. He says that cows' milk contains ready-formed micrococcus cells, but that coagulation does not take place till the conditions for their development are favorable. The addition of rennet, which contains cells of a similar character ready to take on an active condition, produces a development of the micrococcus cells. Völcker and others have demonstrated by numerous experiments that milk is often coagulated by the action of rennet before it becomes sour; and although it is undoubtedly true that caseine owes its solubility to a combination with an alkali, it does not follow that that combination may not be broken up even while the fluid in which it is dissolved is alkaline. It cannot therefore be maintained that the coagulation of the caseine in the ordinary use of rennet is due to the action of lactic acid. When an acid is added to milk, it does not coagulate till there is decided acidity. It would seem therefore that the alkaline constituent of the caseine is not immediately abstracted, because of the slight acidity of the milk in which it is held in solution. It is not unlikely that the coagulation of caseine by rennet has much similarity to its coagulation by the gastric juice, which by a catalytic action has the power of coagulating soluble caseine, and of again dissolving it in a condition which Mailhe calls albuminose, as he does the digested product of all the albuminoids, but which Lehmann calls peptones. The juice of the gastric tubules never effects this transformation unless it contains a free acid, but it is possible that the mucous coat of the stomach when converted into rennet may possess the power of coagulating soluble caseine, although not of digesting it. The antiseptic properties of gastric juice are probably owing to the combined action of the pepsine and lactic acid, and it is not improbable that the development of lactic acid in cheese making arrests putrefactive fermentation upon the same principle. But whatever may be the result of the investigations that are in progress, it is admitted on all hands that the transformation of sugar of milk into lactic acid is hastened by the action of rennet, although coagulation of caseine may precede the lactic acid fermentation. (See FERMENTATION.) In the practice of cheese making the subject of ferments is one that requires to be constantly borne in mind if satisfactory results are to be secured. The spores of various fungi are con-

stantly floating in the air and attaching themselves to and developing in any matrix capable of yielding them nourishment; and as milk is one of the most delicately sensitive of all fluids, the most scrupulous cleanliness should exist in every part of a cheese dairy. The vessels for containing the milk and its products must always be scalded with boiling water as soon as they are emptied, and all the utensils should regularly be subjected to the same treatment. The pastures and all the food and drink of the cows ought to be free from all products of fungoid putrefaction or fermentation of whatever kind; therefore stagnant water or low, sour land should not be suffered in pastures devoted to the grazing of milch cows, and mouldy food should be strictly excluded from their diet. Most of the cheese in the United States is now made at factories, which are carried on by associations of farmers who employ a manager. The usual practice is to send the milk to the factory every night and morning, keeping it as cool as practicable during transportation.—The process of making cheese with the use of rennet which will now be described is that which is followed by the best cheese makers in this country, and is very nearly the same as that by which the celebrated Cheddar cheese is made, in Somersetshire, England. The evening's milk is placed in cooling vats so that it will be brought to a temperature of about 60° by the following morning, when the morning's milk is added and the temperature raised to 80°. This is effected in a manner the most efficient, at the same that it avoids overheating any portion of the milk. A large vat contains the milk, which is gently and equally heated by a water bath, which receives its heat from the circulation of warm water furnished from a cylindrical reservoir heated by a concentric flue placed beneath the vat, or by water contained in a coil of pipe, and heated in a fire box near by. When the milk has reached 80° a sufficient quantity of rennet is stirred into it to produce coagulation in about 40 minutes. It is customary with the Cheddar cheese makers to add sour whey in quantity according to the condition of the milk, adding little or none if any acidity has been developed in it. The whey is used for the purpose of hastening the development of lactic acid, because it is then found that there is less liability to that species of fermentation which results in gaseous and other objectionable products. It is a practice that has not been general in this country, but many of the best cheese makers are now adopting it. When the curd has become sufficiently firm, which may be known by its dividing with a smooth fracture when the finger is passed through it, it is cut with curd knives, one set of which have perpendicular and the other horizontal blades, into small cubes of from a quarter to a half inch in diameter. The contraction of the curd then takes place more rapidly, expressing the whey; and in about 20 minutes it becomes

quite firm, when it is broken up by means of an instrument called a wire shovel breaker into smaller pieces, and the temperature is raised to 98°, the contents of the vat being gently stirred to prevent packing of the curds upon the bottom. When the curd has become sufficiently firm for the operation, and the whey has attained a certain degree of acidity, conditions which can be learned only by experience, it is drawn off by a large spout as rapidly as possible, and the curd is heaped in one end of the vat, which is elevated to facilitate the draining. Exposure to the air hastens the development of lactic acid. In 15 or 20 minutes the particles of curd will have become coherent and form a partially solid mass, which is then cut into pieces and turned over and left until firm enough to break into pieces without danger of expressing the buttery particles, which would be the case if the process were attempted too soon. It is then taken out, placed in a cooler, broken into thin flakes, and spread out to cool still further. In about 20 minutes it is turned over and left until it attains a peculiar mellow and flaky condition, well known to the experienced cheese maker. By this time its temperature has been reduced to about 70°, and it is put into a hoop and pressed gently for 10 or 15 minutes, to express more of the whey, by which a too rapid fermentation is prevented. It is then taken out and cut and broken into pieces about the size of peas by means of a curd mill, after which it is salted. In England 1 lb. of salt is used to 56 lbs. of curd; but in the United States more salt is used—from 2½ to 3 lbs. to 100 lbs. of curd—partly because American dairy men do not drain their curds or express the whey from their cheeses as much as the English. The changes that produce the aroma and flavor of cheese may be produced in less time, or at least may to a certain extent be imitated, by using a large amount of salt and keeping the curing rooms warm. The flavor, however, is always rendered inferior by such means, and irritating and unwholesome properties are engendered. After the salt has been well incorporated the curd is again put into the hoop, a cloth being placed upon the top and bottom, and sometimes around it. It is kept under pressure for 20 or 24 hours, and is then taken out, and any sharp edges that may have been made in pressing pared off. It is then turned and placed in the press again, and generally, especially if the cheese is a large one, bandaged, and kept there for one or two days longer. In many of the factories in this country, however, only 24 hours is allowed for pressing, because of the number that are made. The temperature at which it goes to press is a matter of great importance, because if too high, fermentation with evolution of gas is liable to take place and make the cheese porous. The temperature at which Cheddar cheese goes to press is between 60° and 65°. Care should be taken during the operation that the buttery particles are not

squeezed out, and at the same time the retention of too much whey should be avoided, as that will injure its keeping properties. Much of the excellence of the Cheddar system lies in the proper management of the conditions which affect the different processes of the manufacture. The following are the chief points requiring attention: 1, the early initiation of lactic acid fermentation by using, when indicated, sour whey; 2, the employment of sufficient heat to cause the curds to contract and express the whey; 3, such an exposure to the air as will to the proper extent convert the micrococcus into arthrocooccus cells, or which will, upon any theory, carry the formation of lactic acid to that degree which, with proper care, will prevent future putrefaction; and 4, to cool the curds enough to prevent loss of butter in pressing. After the cheese is pressed it is taken to the curing room, rubbed with melted fresh butter, and turned over once a day until it is ripened. The curing room should be dimly lighted, to avoid flies as well as the chemical action of light, and sufficiently ventilated to keep the air pure. The temperature should be well regulated, being kept for the most part at about 70° both in summer and winter. A higher degree produces too rapid ripening, and below 60° the necessary chemical changes will not take place. It sometimes happens that the milk when it is poured into the vat has some taint that will cause it, after the rennet is added, to take on a fermentation which will result in gaseous products and an offensive flavor and smell. This condition of the milk may be caused by the overheating of the blood of the cows, or from their having partaken of improper food. The effect will be, unless the difficulty is anticipated, the production of what is called floating curds, in consequence of the reduction of their specific gravity by the bubbles of gas. This floating occurs when the curds are broken and the temperature is raised previous to drawing off the whey. When this phenomenon is seen to be taking place, the temperature of the vat should be raised to 100° to cause greater contraction of the curds, and after the whey is drawn off the draining and exposure to the air should be continued longer than usual in order to develop an increased amount of lactic acid. This will be likely to arrest the putrefactive fermentation, and to get rid of the obnoxious products which have already appeared. When a bad condition of the milk is known or strongly suspected, it should be aerated and cooled as much as possible before going into the vat, and enough more rennet than usual should be used to produce coagulation in 30 minutes, and a larger quantity of sour whey than usual should be stirred in at the same time.—Some very fine cheeses are made in England by skimming the night's milk and adding it to that of the morning. Such are often called skim-milk cheeses, although the term more strictly applies to those made of milk all of which has been skimmed, leaving

only a small percentage of butter. Some made in Wiltshire and Gloucestershire of partly skimmed milk are said by Dr. Völeker to compare favorably with good Cheddar, the deficiency in butter being made up by other good qualities. It is the opinion of many good cheese makers that milk may be too rich in butter for the best quality of cheese that will keep well. If nearly all the cream is skimmed from milk, it will not be possible to make it into good cheese, at least by the ordinary English process. At creameries and in the butter-making districts in this country, as well as in England, the making of skim-milk cheeses is practised to a certain extent. The process differs but little from that of making whole-milk cheeses; but as they do not ripen or cure as soon or as evenly, they are made smaller and thinner.—The coagulation of milk by means of hydrochloric acid, as it is practised in Holland in making the most excellent cheeses, deserves more attention than it has hitherto received in other countries. The process is attended with much less difficulty than when rennet is employed, and the coagulation is more complete, yielding an increased product. All the butter is retained in the curd, and the danger of after fermentation is also greatly diminished by avoiding the use of fungous ferments, whose control is always more or less difficult. The principal objection seems to be an ascribed want of flavor, which among most cheese fanciers, especially in England, requires to be somewhat gamy. The Dutch cheese has a sharp taste and high keeping qualities, and notwithstanding it may lack what is called mellowness, its flavor is preferred by many. It probably possesses the advantage of being less liable than cheese coagulated by rennet to contain deleterious or poisonous principles.—There are more varieties of cheese made in Europe than in America, which may be in part attributed to the greater attention which is paid there to economy in food. They may be classified into cream cheeses, whole-milk cheeses, and skim and sour-milk cheeses. To the first class belong Neufchâtel, Vaschrein, Brie, cream Cheddar, and Cotherstone. Neufchâtel is made of pure cream thickened by heat and compressed in a mould. It is made at Neufchâtel-en-Bray, a small town in the department of Seine-Inférieure, France, 25 m. N. E. of Rouen. It is esteemed as a great delicacy, but, from the difficulty of preserving its good qualities, can scarcely be appreciated far from the locality where it is made. Brie, which is also a French cheese, and the Vaschrein of Switzerland, are also made of the purest cream. Both Neufchâtel and Brie cheeses are now largely made in the state of New Jersey, and can be brought to the New York and Philadelphia markets in a better condition than if imported. Stilton and cream Cheddar are made by adding the cream of one milking to the whole milk of the next, in the proportion of one quart of cream

to ten quarts of milk. After stirring, the mass is put into a tub in which a linen strainer has been laid. Coagulation is produced by rennet, the curd is cut into cubes, and without breaking is carefully lifted into a strainer, to allow the whey to drain off, after which it is placed in a hoop seven or eight inches in diameter and eight or nine inches high, having a follower pierced with holes at each end. When fitted, the hoop is placed upon a shelf and turned four or five times a day, the only pressure applied being its own weight. When sufficiently firm, which can only be known by experience, it is bandaged and taken to a curing room whose temperature is about 70°, where it receives its salting, which is performed externally and not by salting the curds. After a time it is sometimes placed in a warmer room for the purpose of developing blue mould, which gives it a peculiar value to some cheese fanciers. Of the second class, or whole-milk cheeses, Cheddar, Cheshire, best Gloucester, and Wiltshire of England, Gouda and Edam of Holland, Gruyère of Switzerland, and most of the American cheeses are examples. The famous Gruyère cheese, made in the canton of Fribourg, Switzerland, which is said by the Swiss to have been the first cheese made by the factory system, is of whole milk, which, to the amount of 100 or more gallons, is heated while fresh in a caldron to blood heat, and rennet added to effect coagulation in about half an hour. The curd is then sliced with a knife and broken with a blunt stick armed with wooden pins, and the heat raised to about 135°. Stirring is continued half an hour after, by which time the curd is divided into small, elastic pieces of the size of peas. A strainer cloth is then drawn under the curds, and they are laid upon a rack to drain, after which they are placed in a peculiar hoop, formed of a thin piece of board bent into a circle, with the ends lapping, but left free to slide over each other to allow the cheese to spread in pressing. The press is a simple lever loaded with a weight at one end. The salting is done after the pressing, the cheese hoop being replaced after each application of salt for a few days, to preserve the form. Jura cheese, made in the Alps, is much like the Gruyère, and they are both known in this country as *Schweitzerkäse*. A factory for making it is established in Oneida co., N. Y., which uses the milk of more than 200 cows; and it is also made in Ohio. It is said, however, that the American Gruyère lacks the flavor of the Swiss, because of difference in the grass upon which the cattle feed. The process for making Parmesan, the cheese of Parma, is said to be precisely similar to that for Gruyère, the difference in the cheese being that the Parmesan is made of skimmed milk. Sour-milk cheeses are made in various parts of Europe. They are often of an inferior quality in consequence of the improper manner in which they are made and the extent to which the fermentation is carried.

Cottage cheese is nothing more than newly prepared curd, drained, broken, slightly pressed, and salted to suit the taste, and is usually eaten in this condition. If kept for some time at a warm temperature, putrefactive fermentation takes place, and ammoniacal gases of an offensive odor are given out. There are persons whose palates are pleased with this product, and it is erroneously supposed by some that this is genuine Dutch cheese. Properly cured sour-milk Dutch cheese is as free from offensive odors as Cheddar, the fermentation having been carefully conducted until all gaseous products cease to be formed; a sharp, clean-flavored, appetizing condiment is the result. It is sometimes flavored with sage and other garden herbs. Roquefort, a French cheese, is made of goats' or sheep's milk; after coagulation by rennet, the curd is subjected to great pressure, and the cheeses are bandaged with coarse cloths and placed on shelves to dry, after which they are taken to caves, where the bandages are removed and they are salted. In 15 or 20 days they become covered with mould, which is scraped off with a knife, the operation being repeated every fortnight for two months, during which the color of the mould is said to be successively white, green, and red, the last color indicating that they are fit to use. *Schabziegerkäse* is made in the canton of Glarus, Switzerland, of curd which has been fermented. It is mixed with the pulverized dried flowers of *Schabziegerklee* (*melilotus cæruleus*, not *M. officinalis*, as is sometimes stated), and pressed in a mould. It is usually eaten grated, spread upon buttered bread, and has a sharp and peculiar flavor much relished by many. In Limburg, Belgium, a cheese is made which is eaten while in a high state of putrefaction. Large quantities are also made in New York, Ohio, Illinois, and Wisconsin. Oneida, Lewis, and Jefferson counties are the principal seats of its manufacture in New York. In 1872, as nearly as can be estimated, about 20,000 boxes were made, of 100 lbs. each, containing from 50 to 60 "bricks," each weighing from 1½ to 2 lbs.—Annotto, a vegetable coloring matter of an orange red, is often used to color cheese; but it is a disagreeable substance, whose use should not be encouraged. (See ANNOTTO.)—Cases of poisoning by cheese are not infrequent, and have lately been sufficiently investigated to show that they are analogous to sausage and salt meat poisoning, and take place from the use of cheese which has been hastily cured, and generally when considerable salt and warmth had been employed. The cases are usually not fatal, but present symptoms of all degrees of violence. It is natural to suppose that a proteine body like caseine, in the presence of fats, would be likely to generate during fermentation substances of a character highly irritating to the mucous membrane, and therefore great caution should be observed in the use of cheese which has an unpleasant odor. Cheese, either new or old,

is not an easily digestible article of food, but when well made is not unwholesome, and may sometimes suitably form quite a large share of the diet of laborers. For further practical and theoretical information, see Willard's "Practical Dairy Husbandry" (New York, 1872), and Watts's "Dictionary of Chemistry."—According to the census, the whole amount of cheese produced in the United States in 1870 was 162,927,382 lbs., of which 109,435,229 lbs. was made in factories and 53,927,382 lbs. on farms. The principal states producing cheese were New York, 100,776,014 lbs.; Ohio, 24,153,856; Vermont, 7,814,879; Illinois, 5,734,004; Massachusetts, 4,131,309; and California, 3,395,074. There were 1,313 factories devoted to the manufacture of cheese, employing 4,607 hands. The capital invested amounted to \$3,690,075; wages paid during the year, \$706,566; gallons of milk used, 116,466,405; value of all materials used, \$14,089,284; of cheese produced, \$16,710,569; other products, \$61,096. The number of cows supplying one factory ranges from 100 to more than 1,000, the average being about 400. In 1871 a factory in Chautauqua co., N. Y., had registered as the whole number of cows, 1,734. During the year ending June 30, 1873, 66,204,024 lbs. of cheese, valued at \$7,752,918, were exported from the United States, of which 52,056,926 lbs. went to England, and 8,428,396 to Germany.

CHEESHAHTEAUMUCK, Caleb, an Indian, graduate of Harvard college (1665), born in 1646, died at Charlestown, Mass., in 1666. He was the only Indian who ever graduated from that college.

CHEEVER, Ezekiel, an American teacher, born in London, Jan. 25, 1615, died in Boston, Aug. 21, 1708. He was the son of a linen draper, and the pure Latinity of some essays and verses written by him in 1631, and which are still extant among his manuscripts, shows that he had enjoyed superior opportunities of classical training. He came to America in 1637, landing at Boston, and in the following year accompanied Davenport and Eaton to Quinnipiac, and assisted in founding the colony of New Haven. His name appears on the plantation covenant in June, 1639. He was chosen one of the deacons of the church soon after its organization, occasionally officiating as a preacher. He taught a public school there from the foundation of the colony in 1638 till 1650, and represented the town in the general assembly in 1646. He was master of the grammar school in Ipswich, Mass., in 1650-'51, when he took charge of the free school in Charlestown, where he taught nine years. In 1670 he was called to Boston to take charge of the free school, now known as the Latin school. In this invitation the governor, magistrates, clergymen, and selectmen of Boston united. He remained at the head of this school for 38 years, and died at the age of 93, "retaining," says Cotton Mather, who preached his funeral sermon, "his

abilities in an unusual degree to the very last, his intellectual force as little abated as his natural." While teaching at New Haven Mr. Cheever prepared the "Accidence, a short Introduction to the Latin Tongue," which in 1785 had run through 20 editions, and was for more than a century the hand-book of the Latin scholars of New England. He was also the author of a little treatise entitled "Scripture Prophecies Explained, in three short Essays."

CHEEVER. I. George Barrell, D. D., an American clergyman and author, born at Hallowell, Me., April 17, 1807. He graduated at Bowdoin college in 1825, at the Andover theological seminary in 1830, and was ordained pastor of the Howard street Congregational church, Salem, Mass., in 1832. While at Andover and Salem he contributed in prose and verse, on literary and theological topics, to the "North American Review," "Biblical Repository," and other periodicals. He engaged in the Unitarian controversy, in connection with which he wrote a defence of the orthodoxy of Cudworth. Espousing the temperance cause, he published in a Salem newspaper, in 1835, a dream entitled "Deacon Giles's Distillery," in which the liquors were graphically characterized as containing demons in an *inferno*. The article was widely circulated with illustrations as a temperance tract. Deacon Giles was deemed a veritable person, and the publication resulted in a riotous attack upon Mr. Cheever in the street, his trial and conviction for libel, and his imprisonment for 30 days in the Salem jail. He resigned his pastorate the next summer, and passed the following 2½ years in Europe and the Levant, contributing letters to the "New York Observer." On his return in 1838 he became pastor of the Allen street Presbyterian church, New York, and soon after delivered lectures on the "Pilgrim's Progress," and on "Hierarchical Despotism." He went again to Europe in 1844, as corresponding editor of the "New York Evangelist," of which journal he was principal editor for a year after his return, in 1845. In 1846 he was installed over the new Congregational church of the Puritans in New York. Upon the establishment of the "New York Independent" in 1848, Dr. Cheever became a weekly contributor to it of religious, literary, critical, and political articles. He also contributed scholarly papers to the "Bibliotheca Sacra." Among his works are commonplace books of prose and poetry (1828 and 1829); "Studies in Poetry" (1830); an edition of the "Select Works of Archbishop Leighton" (1832); "Lectures on the Pilgrim's Progress" (1844); "Wanderings of a Pilgrim" (1845 and 1846); "Journal of the Pilgrims at Plymouth, New England, in 1620, reprinted from the original volume" (1848); "Windings of the River of the Water of Life" (1849); "Voices of Nature" (1852); "Powers of the World to Come" (1853); "Lectures on the Life, Genius, and Sanctity of Cowper" (1856); "God against Slavery"

(1857); and "Guilt of Slavery and Crime of Slaveholding" (1860). **II. Henry Theodore**, an American clergyman and author, brother of the preceding, born at Hallowell, Me., in 1814. He graduated at Bowdoin college in 1834, and in 1835-'6 was a correspondent from Spain, France, and Louisiana of the New York "Evangelist." He afterward studied theology at Bangor, visited the Sandwich Islands, and was successively minister of Congregational churches at Lodi, N. J., in New York, at Greenport, L. I., at Jewett City, Conn., and since 1864 at Worcester, Mass. He was secretary and agent of the church anti-slavery society from its origin in 1859 to its close in 1864. He has published "Life in the Sandwich Islands" (1850); "Memorials of Nathaniel Cheever, M. D." (1851); "Memoir of Walter Colton" (1852); "The Pulpit and the Pew" (1858); "Tracts for the Times" (1859); "Way Marks in the Moral War with Slavery" (1861); and several volumes of travel and adventure among the islands of the Pacific, for the young.

CHEHALIS, a W. county of Washington territory, bordering on the Pacific, and watered by the Kwantli river and the Chehalis and its tributaries; area, 1,600 sq. m.; pop. in 1870, 401. Gray's harbor, a capacious and landlocked bay, is in this county. Timber is abundant, and the soil is very fertile. The chief productions in 1870 were 3,345 bushels of wheat, 3,345 of oats, 9,860 of potatoes, 746 tons of hay, and 21,890 lbs. of butter. There were 129 horses, 505 milch cows, 1,145 other cattle, 847 sheep, and 293 swine. Capital, Montesano.

CHEIROPTERA. See BAT.

CHEIROTHERIUM. See LABYRINTHODON.

CHEKE, Sir John, an English scholar, born at Cambridge, June 16, 1514, died Sept. 13, 1557. After distinguishing himself as a classical scholar at St. John's college, Cambridge, he was selected to fill the new professorship of Greek founded by Henry VIII. In this position he labored to restore the original pronunciation of Greek, in which he was thwarted by Bishop Gardiner, then chancellor of the university. In 1544 he was appointed, with Sir Anthony Cooke, tutor to Prince Edward, and he appears also to have had the princess Elizabeth under his care. When Edward VI. came to the throne he rewarded him by lucrative offices in the church, caused him to be elected provost of King's college, and made him commissioner to revise the ecclesiastical laws, gentleman of his household, knight, and in 1553 clerk of the council, privy councillor, and one of the secretaries of state. On the king's death he supported the movement that placed the crown for a few days on the head of Lady Jane Grey. For this, on Queen Mary's accession, he was sent to the tower, but was pardoned after a year's imprisonment. Foreseeing evil days, he obtained permission to sojourn on the continent, and fixed his residence at Strasburg, where he was prominent in the services of the English church established

there. This gave offence to the powers in England; his property was confiscated, and he was compelled to teach Greek for a livelihood. In 1556 he was inveigled, through the means of the British minister, to Brussels, to meet his wife. On returning he was arrested on a slight charge, and was conveyed to England, where the queen sent Feckenham, dean of St. Paul's, to convert him, with the alternative of going to the stake if impenitent. Cheke's constancy gave way. He made a public recantation; but, being compelled to assist at the condemnation of Protestants, he died of vexation and remorse, and was buried in St. Alban's church. He wrote several learned religious works in Latin. His only English composition is a pamphlet published in 1549, entitled "The Hurt of Sedition, how Grievous it is to a Commonwealth." He left several works in MS., among them a translation of Matthew's Gospel into words derived mainly from Saxon roots; also a plan of spelling words by sound, almost similar to that since developed as phonography. He is, however, chiefly distinguished for the impulse he gave to the study of the Greek language and literature. Strype's "Life of Cheke" appeared at London in 1705.

CHEKIANG, an E. province of China, bordering on the Pacific, and including the Chusan archipelago, between lat. 27° and 31° N., and lon. 118° and 123° E., traversed by the great canal, the Tsientang and other rivers; area, about 40,000 sq. m. According to Chinese authorities, the population in 1864 was 26,756,784. Baron Richthofen (Shanghai, 1871) concedes an aggregate population of barely 6,000,000, of whom 2,000,000 live in the five chief cities. But his estimate does not seem to be corroborated. Chekiang is among the most fertile and prosperous regions of China; and a large business is transacted in the principal ports, Ningpo and Hangchow, which are open to foreign commerce. The staple export is silk. The green tea country is situated near the Tsientang river, W. of Ningpo, and tea is extensively exported, as well as cotton, indigo, camphor, coal, and fruit. Gold and silver stuffs, paper, and fermented liquors are manufactured and largely exported. Hangchow is the capital, but the governor general of the two provinces of Fokien and Chekiang had his official residence in 1871 at Foochow, the capital of Fokien.

CHELARD, Hippolyte André Jean Baptiste, a French composer, born in Paris, Feb. 1, 1789, died in Weimar, Feb. 12, 1861. The son of a musician, he studied in Paris, Rome, and Naples, and his first comic opera, *Casa da vendere*, was performed in the latter city in 1815. In 1816 he became a violinist at the grand opera in Paris, and a music teacher. The above mentioned opera was produced at the Italian theatre in 1816, and *Macbeth*, a lyrical opera in three acts, at the grand opera in June, 1827. Although Rouget de Lisle wrote the libretto, and the trio of the witches and the choruses produced a great dramatic effect, the opera was not

successful in Paris; but Chelard having added an act, and produced a German version, it was favorably received in Munich in 1828, and the king of Bavaria appointed him chapelmaster. Having returned to Paris to meet with new failures, he went back to Munich in 1830, and thence to London as leader of the German opera (1832-'3). In 1836 he went to Weimar as chapelmaster. Here in 1848 he was thrown into the shade by Liszt. Having been pensioned in 1852, he made in 1854 a not very successful attempt in Paris, and soon afterward he went back to Weimar. His productions were much more popular in Germany than in France. His best opera is the *Herrmannschlacht*, first produced in 1835.

CHELMSFORD, Frederick Thesiger, baron, an English lawyer, born in London in July, 1794. His father was a collector of customs in the island of St. Vincent. In 1803 he entered the navy, and served as midshipman during the bombardment of Copenhagen in 1807; but his father's West India estate having been destroyed by a volcanic eruption, he retired from the naval service to study law. He was called to the bar in 1818, became one of the most brilliant leaders of the home circuit, and in 1834 king's councillor. He was returned to parliament in March, 1840, in the conservative interest. He was solicitor general in 1844-'5, attorney general 1845-'6, and again in 1852, and lord chancellor from February, 1858, to June, 1859, and from June, 1866, to February, 1868. In 1858 he was raised to the peerage as Baron Chelmsford, and he is one of the leaders of the conservative party in the house of lords. He married a niece of Major Pierson, who fell at Jersey in 1781.—His elder son, **FREDERICK AUGUSTUS**, born in 1827, distinguished himself in the Crimea, India, and Abyssinia, and was appointed in 1868 aide-de-camp to the queen and adjutant general to the forces in India.

CHELSEA, a city of Suffolk co., Massachusetts, separated from Charlestown on the S. W. by Mystic river, which is crossed by Chelsea bridge, 3,300 ft. long. It is connected with Boston by the Eastern railroad, and also by horse railroad by way of Charlestown and Chelsea bridge. Winnisimmet ferry, the most ancient in the United States, dating from 1631, runs from the foot of Winnisimmet street, Chelsea, to the foot of Hanover street, Boston, a distance of about 1½ m. The Grand Junction railroad also passes through the city. Chelsea beach, in Revere, an adjoining town, about 5 m. from Boston, is about 3 m. long, and is much resorted to in summer. The growth of Chelsea has been steady since 1830. In that year the population was 770; in 1840, 2,390; 1850, 6,701; 1860, 13,395; 1865, 14,403; 1870, 18,547. The principal public buildings are the city hall, the naval hospital, connected with the navy yard at Charlestown, the marine hospital, the academy of music, the masonic and odd fellows' halls, and Winnisimmet hall.

The city is included in the Boston customs district, and most of its inhabitants do business in that city; but there is some manufacturing, the principal establishments being a woollen mill, a brass foundry, an iron foundry and machine shop, an establishment for casting furnaces, ranges, and stoves, one manufactory each of linseed oil, table salt, fire brick, rubber goods, boot and shoe stiffenings, brooms, chairs, carriages, chewing gum, marble work, washing machines, mattresses, and paper boxes, three each of oil and varnishes, soap, bricks, varnishes and japan, and worsted goods, and one brewery. There is a national bank, with a capital of \$300,000, and a savings bank, with deposits in 1871 amounting to \$590,736. In 1872 the valuation of property was \$16,707,343; total taxation, \$277,055 48; city debt, \$1,262,700, of which \$1,057,800 was funded. In 1871 there were 3,092 houses in the city. Chelsea is divided into four wards. The government is vested in a mayor, a board of aldermen consisting of two from each ward, and a common council of 19 members. The police duty is performed by a city marshal and 19 assistant marshals, and there is a police court. The fire department is under the charge of a chief engineer and two assistant engineers, and has two steam engines, a hook and ladder company, and three hose companies. The Chelsea water works are under the charge of three commissioners. The water is brought from the Mystic water works in Charlestown, and was first introduced in 1867. The principal charitable institutions are the Winnisimmet benevolent society and the ladies' union relief society. In 1872 the city appropriated \$4,896 28 for the support of the poor. The school committee, consisting of two members from each ward, has under its control a high school and 3 grammar and 12 primary schools. In 1871 there were 4 male and 58 female teachers, and an average attendance of 2,800 pupils. The free public library, which was opened Jan. 1, 1870, contains about 6,000 volumes. There are also two circulating libraries and a weekly newspaper. There 13 religious societies, viz.: 2 Baptist, 2 Congregational, 1 Episcopal, 2 Methodist, 1 Roman Catholic, 1 Unitarian, 1 Universalist, 1 Second Advent, 1 Spiritualist, and 1 Christian band. Chelsea was settled in 1630, and was called Winnisimmet. It was a part of Boston till 1738, when with two other places it was organized as the town of Chelsea. It was incorporated as a city in 1857.

CHELSEA, a parish and parliamentary borough of England, on the left bank of the Thames, formerly a village about 2 m. from London, but now a portion of its suburbs, belonging to the county of Middlesex, and constituting a part of the hundred of Ossulston; pop. of Chelsea district in 1871, 71,086, and of the borough, 258,011. It derives interest from the celebrated military asylum for invalid soldiers known as Chelsea hospital, erected here by Sir Chris-

topher Wren in the reign of Charles II., who laid its foundation stone, Feb. 16, 1682. It was completed in 1690 at an expense of £150,000. It accommodates upward of 500 resident pensioners, besides whom there are about 70,000 out-pensioners. The annual expenditure for the maintenance of this establishment is about £1,000,000. The body of the duke of Wellington lay in state in Chelsea hospital for a few days previous to the funeral (November, 1852). The royal military asylum for the support and education of children of soldiers (especially orphans), with accommodations for 1,000 boys and girls, is in Chelsea. A children's hospital was opened in 1866. Prominent among the educational institutions are a normal school for males and one for females. Adjoining the military hospital are the botanical gardens of the apothecaries' company, occupying four acres on the bank of the river. The old parish church forms the termination to a long grove called Cheyne walk; and the churchyard contains monuments to Sir Thomas More and Sir Hans Sloane. A beautiful suspension bridge completed in 1858, 915 ft. in length including abutments, connects Chelsea with Battersea. The steamboat traffic is accommodated by three piers. In 1871 was laid the first stone of the embankment on the N. side of the Thames. Cremorne gardens in Chelsea are a favorite popular resort. In 1867 Chelsea was constituted a borough, comprising also Fulham, Hammersmith, and Kensington, entitled to two members of parliament.

CHELTENHAM, a market town and parliamentary borough of Gloucestershire, England, on the river Chelt, 86 m. N. W. of London; pop. in 1871, 44,519. It is celebrated as a fashionable watering place. It lies in an extensive valley open to the south and west, but sheltered on other sides by an amphitheatre formed by the Malvern, Cotswold, and Leckhampton hills. The scenery on every side is noted for its picturesque beauty. Excepting a large railway carriage and wagon manufactory, the town has no manufactures, and but little trade beyond supplying the wealthy invalids who make it their residence, and whose houses and villas adorn the suburbs and surrounding country. The place possesses the usual attributes of a fashionable resort: assembly rooms, theatre, reading and billiard rooms, club house, literary and philosophic institute, horticultural and choral societies, cricket ground, race course, &c. The parochial church of St. Mary's is an ancient Gothic structure, in the decorated style, cruciform in shape, with a tower rising from the intersection of the cross, and with a lofty octagonal spire containing a peal of eight bells. There are 19 other churches and chapels, and numerous educational and benevolent institutions. Among the former is a free grammar school founded in 1578. Cheltenham proprietary college was erected in 1843, and is attended by over 600 students. The college building is an imposing specimen of the Tudor

collegiate style, with a frontage of 240 ft. There are four springs: the Royal old well, Montpelier spa, Pittville spa, and Cambray spa, with numerous baths. The water is a saline

Cheltenham College.

acidulous chalybeate, its main constituents being chloride of sodium, sulphate of soda, sulphate of magnesia, carbonic acid, and carbonate of iron, and is esteemed in bilious ailments. The first spring was discovered in 1716, but it was not till 1788, when George III. visited the town for his health, that it became a place of fashionable resort. Since then its growth has been very rapid.

CHEMISTRY, the science which investigates the composition and certain properties of material substances. Nothing is certainly known of the derivation of the term, but it is most probably from *Xημεία* (*Chemia*), the original name of Egypt, in which country it is supposed to have originated; hence it was called the Egyptian art. Others derive it from *χημική* or *χημική*, relating to juices; hence the word was formerly written chymistry. The oldest author who mentions it is Julius Maternus Firmicus, in the reign of Constantine, about A. D. 340. Suidas defines chemistry as the making of gold and silver; Libavius, in 1595, as the art of making chemical preparations and of extracting the pure essences in a separate form from mixtures; Lémery, in 1675, as the art which treats of separating the different substances which occur in mixtures; Bergman, in the latter part of the 18th century, as the science which investigates the components of bodies in regard to their nature, their properties, and the manner in which they are combined; Macquer, about the same time, as the science which makes known to us the nature and properties of all bodies by composing and decomposing them. To the last two definitions, which express quite fully the ideas of chemists of the present day, may be added that of Berzelius: "Nature is composed of certain elementary bodies or elements. The knowledge of these bodies, of their mutual combinations, of the forces by which these combinations are brought about, and of the laws in accordance with which these forces act, constitutes chemistry."—Chemistry is often incorrectly spoken of as a science of recent origin. This view may be readily disproved. It would be impossible to determine at what exact period

it became so far developed as to deserve the name of science. Many chemical facts must have been known from the earliest times. As far back as history goes they are treated of. Only by the gradual collection and explanation of such facts could chemistry become a science. The Egyptians possessed considerable chemical knowledge. The smelting of ores and working of metals must have been brought to a high degree of perfection among them; otherwise many of their works of art, still existing, could not have been made. Their skill in dyeing implies a knowledge of the necessary chemicals and mordants. They also made glass, even colored, and knew how to prevent the decomposition of dead animal matter. The priesthood evidently possessed more or less knowledge of pharmaceutical chemistry. The Phœnicians dyed, made glass, and imported tin. The Israelites seem to have obtained some chemical knowledge, especially relating to metallurgy, during their sojourn in Egypt; they were acquainted with gold, silver, copper, tin, lead, and iron. The Greeks in the time of Homer seem to have had only what chemical knowledge they had derived from the Egyptians and Phœnicians. The metaphysical direction of the Greek mind was not calculated to advance the science by experimental investigations. They attempted, on the other hand, to explain the composition and origin of matter by philosophical speculations, as seen in the discussions regarding the elements, some five or six centuries before Christ. The views advanced by Aristotle on this subject long exerted a great influence on the science. He considered substances to be the result of the mixture of several fundamental properties, and their components or elements only as bearers of these properties, not at all as material, undecomposable substances which could be extracted experimentally. According to Aristotle these properties are those evident to the senses, viz.: hot, cold, dry, wet, heavy, light, hard, soft, &c. He recognized only the first four of these, because the others are less general and for the most part only secondary results of the union of the preceding. Hence his conclusion that there are four fundamental properties, hot, cold, dry, and wet, which characterize the four elementary conditions of matter, or elements, fire, air, earth, and water, of which all substances are composed, and from which their peculiarities are derived. He admits that each element possesses two of these properties at the same time, and since no element can have at once two totally opposite properties, cannot be simultaneously wet and dry, only four combinations are possible. Thus, simultaneous dryness and heat form fire; heat and moisture, air; cold and dryness, earth; cold and moisture, water. The Romans derived some chemical knowledge from other nations. They were acquainted with the metals previously mentioned, also with mercury, the power of which to dissolve gold they made use of in gilding. They knew of various alloys, of steel,

glass, vinegar, and soap. Their knowledge of dyeing was less than that possessed by the Egyptians.—Although but little is known of the progress of chemistry from the 1st to the 4th century A. D., it is probable that much of the knowledge which had long been kept secret by the Egyptian priests was now published and taught at Alexandria. Previous to the latter period chemistry had consisted only of a collection of empirical facts without intimate connection or definite purpose, upon which no theoretical views of any kind had been founded. It has been a peculiarity of chemistry, that while preserving its name and connection as a science it has had temporarily, at various times, special objects in view, to the attainment of which all its energies were directed for the time, while what is now regarded as the true aim of the science was used only as a means of obtaining the desired result. Such a period now commenced. It was characterized by the purpose which the science served, as well as by a theory upon the composition of the metals. All chemical facts were now studied under a certain connection for the purpose of solving a given problem: how to convert base metals into noble, as iron or lead into silver or gold. This idea is first mentioned by Greek authors of the 4th century, who speak of it as a thing already well known. It probably originated with the Egyptians, from whom it passed to the Arabs when they overran Egypt in the 7th century. From the middle of the 8th century the Arabs paid much attention to chemistry. From them its study passed through Spain into northern Europe. The purpose was still the transmutation of metals, the discovery of the philosopher's stone, the touch of which would convert mercury into gold, and at a later period also regarded as capable of curing all diseases. The first chemical theory appears in the 8th century. It consisted essentially in this: All metals are composed of two constituents, upon the relative quantity and purity of which the nature of the metal depends. These components were called sulphur and mercury. Although not possessing all the properties of ordinary sulphur and mercury, they derived their names from these last, which were supposed to contain a large proportion of them, but their properties were nevertheless different. The sulphur and mercury of the alchemists must be regarded, therefore, as conventional elements, deriving their names from certain analogies which they bore to ordinary sulphur and mercury. By mercury, undecomposability appears to have been understood; it was also regarded as the cause of metallic lustre and of malleability; by sulphur, on the contrary, decomposability was understood; these terms referring to the behavior of substances when subjected to fire, at that time regarded as the most powerful chemical agent. The various metals were supposed to be composed of these two bodies in different quantities, degrees of purity and of fixity (affinity?). The fusibility

of the metals was considered to depend upon the fixity of these ingredients; their color upon the relative amount of sulphur which they contained. The author of this theory is unknown. It is fully developed in the writings of the Arab Geber, who refers it to the ancients. It experienced but slight alteration till toward the end of the alchemical period, when the idea of salt was added to those of mercury and sulphur. Among the Arabs, physicians were the principal chemists, many of them being highly scientific men. The writings of Geber, in the latter half of the 8th century, indicate the amount of chemical knowledge which they then possessed. He describes the metals very accurately, and mentions the different degrees of affinity which mercury has for gold, silver, lead, tin, and copper. He knew how to convert metals into oxides by means of heat, and how to purify native sulphur by solution in alkaline lye, and reprecipitation by vinegar. Several metallic sulphides were also known to him, as well as the fact that metals increase in weight and change color when heated with sulphur. The Arabs, unlike some of their predecessors, did not consider simple change of color in a metal to be transmutation. They demanded an entire change of its properties—that it should be made like some other metal. Transmutation was regarded by them in the light of a scientific problem as yet unsolved. Their knowledge of salts was comparatively extensive, alum, saltpetre, sal ammoniac, and green vitriol being accurately described. The carbonates of the fixed alkalies, and the use of lime to render them caustic; the preparation of sulphuric acid by the distillation of alum; of nitric acid by the distillation of saltpetre and green vitriol; the preparation of strong acetic acid from vinegar, and of *aqua regia* from nitric acid and sal ammoniac, are all described by Geber. By means of the acids thus obtained, artificial salts were prepared, as nitrate of silver and bichloride of mercury; gold was also dissolved. They purified their preparations by distillation, by recrystallization, and by sublimation. The purification of the noble metals by cupellation, the use of the water bath, and processes of filtration, were also known. Several words still in common use, as alkali, alcohol, &c., originated with them. Geber himself published a special work on the construction of chemical furnaces.—The importance of the Arabs as chemists ceased with the 12th century; not, however, before they had awakened in other nations an enthusiasm for the science. During the 13th century it had spread over the greater part of northwestern Europe. The views of Albertus Magnus, who flourished in Germany during the 13th century, will serve as an example of those of his day. Believing fully in the transmutation of metals, he considered it easier to convert them into each other when their properties are analogous. Thus gold can be more readily made from silver than from any other metal, for the mixture of which it is com-

posed is very similar to that which forms silver. Indeed, it would only be necessary to change the color and weight of the latter, in order to obtain gold. He admits that different species of bodies cannot be converted one into the other. The metals, however, he regarded as mere varieties of one and the same species, being all composed alike. His views concerning this composition are essentially the same as those of Geber, but he believed that, besides sulphur and mercury, the metals must contain water, to the cold of which their solidity is due, seemingly mingling a portion of Aristotle's doctrine with that of Geber. The knowledge of practical chemistry detailed in his works is in advance of that possessed by Geber. For example, he describes the separation of silver from gold by means of nitric acid; a method of preparing metallic arsenic; and observed that sulphur attacks all metals, except gold, when heated with them. Contemporary with Albertus lived Roger Bacon, a most able diffuser and promoter of chemical science. At the same time, Raymond Lully made many new and important observations, but introduced an obscure style of writing, and fell into many absurdities, like those which soon became characteristic of alchemy. The transmutation of metals was now no longer spoken of as a possibility, but as a well established fact. In the 14th century alchemy had become diffused over the greater part of the civilized world. It was, however, especially among the priesthood that its followers were to be found, in spite of its prohibition by a bull of Pope John XXII. in 1317. In the latter part of the 15th century flourished Basil Valentine. In addition to the elements, sulphur and mercury, of the earlier alchemists, he mentions salt. From these three substances he supposes that not only metals but all substances are composed. He first clearly described bismuth and zinc; prepared antimony and several new salts; also muriatic acid, by distilling common salt with green vitriol. He knew how to precipitate copper from its solutions by means of iron, also gold by means of mercury, and had much general knowledge of precipitation. With him qualitative analysis first appears. He detected iron in many specimens of hard tin, copper in the brittle iron of Hungary, and silver in the copper from Mansfeld. He explains how a similar occurrence of the noble metals in the base metals of commerce may have given rise to many of the so-called transmutations of false alchemists.—The great impulse given to all branches of learning by the remarkable events of the 15th century had its effect on chemistry. The overthrow of the Byzantine empire, which scattered many of its learned men over western Europe, the invention of printing, and, above all, the growing tendency of men to think for themselves, were of peculiar importance to it. The implicit confidence hitherto placed in noted authorities began to diminish, and their theories to be questioned. The ground was made ready for a new

system. This was inaugurated by Paracelsus, in the first quarter of the 16th century. It fills a well defined period in chemical history, enduring till the middle of the 17th century. The views regarding the transmutation of metals remained unchanged, but gold-making was no longer the chief aim of the leading chemists. Indeed alchemy, as an art, soon became separated from chemistry. The characteristic of this period was the intimate connection between medicine and chemistry, the whole purpose of the latter being to cure disease. As its purpose was thus elevated, it passed into the hands of educated men, through whom the amount of chemical knowledge was rapidly increased. Paracelsus regarded sulphur, mercury, and salt as the elements of all substances, organic and inorganic. His ideas of sulphur and mercury correspond with those of the earlier alchemists, while that of salt is opposed to that of mercury, the former being typical of solidity and incombustibility, while the latter is expressive of volatility without decomposition. Besides giving a great impulse to the science, Paracelsus introduced numberless chemical preparations into use in medicine, rendering them familiar to physicians and apothecaries, whence the latter were often induced to occupy themselves with the study of chemistry. The controversies between the followers of Paracelsus and his adversaries also excited great interest in the science. At this epoch Agricola (1490-1555) flourished in Saxony. Standing aloof from the great chemical questions of the day, he occupied himself almost exclusively with metallurgy, in which specialty he became very distinguished by his writings. He first describes clear processes of smelting metals and of assaying ores. He may also be regarded as the founder of this branch of chemical science. Distinguished among the opposers of the mystical style of the alchemists, and for his exposition of their charlatanry, was Libavius (died 1616). Many valuable observations are also due to him. He prepared sulphuric acid by burning sulphur with salpêtre, and proved its identity with the acid obtained by roasting green vitriol or alum. By distilling tin with corrosive sublimate he prepared bichloride of tin, still known as the fuming liquor of Libavius. The ideas concerning elements entertained by Van Helmont (1577-1644) differ essentially from those of preceding chemists. He rejected the four elements of Aristotle, for fire is not a substance; heat and cold are only abstract qualities, and not material things; therefore fire cannot be contained in any substance as a material component. He denounced, on the other hand, the elements of the alchemists, sulphur, mercury, and salt, and especially the theory that they were elements of the animal body, in proof of which, according to him, no facts existed. He regarded water as the chief ingredient of all things. It could be obtained by burning any combustible body. From it all parts of vegetables are formed, their

earthy as well as combustible portions. In proof of this, Van Helmont made the following experiment: A willow twig weighing 5 lbs. was planted in a pot containing a known quantity of thoroughly dried earth; this was covered to protect it from dust, and watered daily with rain water during five years. The willow, meanwhile, grew large and strong, weighing 164 lbs., although the earth in the pot, when again dried, had only lost 2 oz. This was regarded as proof positive that water alone forms plants and the mineral matters contained in them, while animals obtain their components directly from plants. Van Helmont introduced the term gas into chemistry, described several different kinds of gases, and distinguished them from vapors. As the practical chemist of this period, Glauber (1604-'68) stands preëminent. By improving the processes of preparing the mineral acids, by the discovery of salts, and by observing many new facts, he did great service. By synthesis he obtained a knowledge of the composition of many substances. It is worthy of remark that, during the latter half of the 17th century, Tachenius made the first approximately correct quantitative chemical statement which occurs in the history of the science, viz.: that metallic lead when burned to red lead increases its weight by $\frac{1}{10}$. In the latter half of the 17th century the foundation of several learned societies promoted and advanced the study of chemistry as well as of the other sciences.—During the continuance of this period of intimate connection between chemistry and medicine a great amount of chemical knowledge had been collected; the metals and their compounds were well known, as were the three principal mineral acids and their combinations with the alkalis. Toward its close a mass of observations, the material with which the structure of modern chemistry has been reared, invited explanation and classification. Important views were at this period advanced by Boyle (1626-'91). He first treated the question of elements from the same point of view as has been taken by modern chemists. He proved more clearly than any of his predecessors that the four elements of Aristotle were inadmissible, and how little the elements of the alchemists were calculated to afford a rational conception of the composition of bodies. He thought that, rather than seek to explain the primary elements of matter, which admit of various views, attention ought to be specially directed to those ingredients which can be separated and isolated as such. If these cannot be further decomposed, they should be called elements, although he admits that they may be still further decomposed as knowledge increases. This clear definition was in his eyes much better calculated to advance the progress of chemical knowledge than the vague ideas expressed in the theories of Aristotle and the alchemists. Boyle's views, however, were not admitted by his contemporaries. He also first defined acids and alkalis in reference to their action on vegetable colors, and

showed that what has been dissolved in the one may be precipitated by adding the other. In applying this to analysis, he made a great step, the so-called dry method of analysis having been previously exclusively used. To this day several reactions first described by Boyle are in common use; for example, the detection of ammonia by adding lime to the matter containing it, and observing the fumes that are formed in presence of an acid; also the detection of silver by muriatic acid. He likewise made many observations of affinity. Nicholas Lémery (1645–1715), a famous lecturer at Paris, deserves mention for his efforts in the diffusion of chemical knowledge. As a clear and systematic writer, he was justly celebrated.—Another modification of views regarding the elements, which exerted great influence, was expressed by Becher (died 1682). According to him, all inorganic bodies are composed of earthy ingredients. There are three elementary earths, the fusible, the combustible, and the mercurial, severally principles of fluidity, combustibility, and volatility. These three earths are present in all metals, combined in different proportions. When combined with water they form the salts, and also a universal acid which is the basis of all acids. He regarded the calcination (oxidation) of metals and combustion in general as a process of decomposition depending on the expulsion of the combustible earth by means of fire. A simple body incapable of decomposition could not burn, for every body capable of burning must contain within itself a cause of its combustibility. This doctrine was soon adopted by Stahl, and under the name of the phlogiston theory characterized an epoch in the history of the science. Chemistry now first stands out on an equality with the other natural sciences. Its aim is no longer either the making of gold or the curing of disease. A desire to acquire a knowledge of the composition of bodies, to explain the phenomena which accompany their formation and decomposition, and to ascertain what relation exists between their properties and their composition, became now the motive of chemists. Modern chemistry, properly so called, now commenced. The first special problem which attracted attention was the explanation of the phenomena of combustion and oxidation. The analogy between these processes had been long observed and often considered. The ancients regarded combustion as dependent upon the separation of fire, apparently believing the latter to be something material. This view was admitted for a long period. The alchemists expressed a similar idea by their figurative sulphur, which was supposed to be expelled when a body burned. For the term sulphur, Becher substituted combustible earth, and defined more clearly the idea that it was separated during combustion. The notion that combustion destroys was undoubted; something was separated, causing the appearance of flame, while the incombustible residue was one of the components of the

compound which had been destroyed. In like manner, when a metal was oxidized, the calx (oxide) was considered to be an educt from the metal. The famous phlogiston theory of Stahl (1660–1734) was a more accurate expression of these views. According to him, all combustible bodies must contain one and the same ingredient, to which they owe their common property, combustibility. This combustible matter he calls phlogiston; its existence, although entirely hypothetical, was regarded by Stahl as being so certain that it was hardly worth while to isolate it, and but few attempts to do so were made by his immediate followers. Later it was thought to be identical with hydrogen. Expressed in the language of the present day, phlogiston may be regarded as the opposite of oxygen. What is now deemed a combination with oxygen was considered by Stahl to be the result of a separation of phlogiston. During combustion phlogiston is expelled, while the other constituents of the compound remain. Charcoal, which leaves little or no residue when burned, was thought to be nearly pure phlogiston. In general, the combustibility of bodies was supposed to depend on the proportion of phlogiston which they contain. On examining the residues left by different substances after their phlogiston had been expelled, it was thought that a knowledge of their original constitution could be obtained. Experience was thus supposed to teach that phosphorus is a compound of phosphoric acid and phlogiston; that the metals are composed of calxes and phlogiston. If bodies from which the phlogiston has been expelled are heated with others rich in phlogiston, the latter give back phlogiston to the former and the original compound is produced. Thus, when a metal calx is heated with charcoal, the original metal is formed. Besides combustibility, Stahl referred color, solubility in acids, and other chemical properties of bodies, to the amount of phlogiston contained in them. For example, he showed that metals which had been deprived of their phlogiston could no longer unite with sulphur. These ideas were greatly extended by his followers. Stahl's observations of new facts and upon affinity were numerous and valuable. Although unable to free himself entirely from the vague speculations of the alchemists, he adopted in general the idea of elements suggested by Boyle, regarding as such all peculiar constituents of matter which by uniting with each other and with phlogiston form compound bodies. At this period investigations to ascertain what substances should be regarded as elementary commenced. Thus the metal calxes (oxides) were considered to be elements, as were sulphuric and phosphoric acids, &c. Boerhaave (1668–1738) and Homberg (1652–1715) were especially diffusers of chemical knowledge. The *Elementa Chémia* of the former, published in 1724, exerted an influence which has probably never been surpassed. His experiments made in order to disprove certain statements of the

alchemists deserve mention. It had been stated that mercury could be converted into an infusible metal when subjected to the continued action of heat. Boerhaave maintained a quantity of mercury at a moderate heat during 15 years without effecting such transformation. Another portion of mercury, being strongly heated in a closed vessel for six months, remained unaltered. It had also been stated by the alchemists that mercury could be converted by repeated distillation into a more volatile body. Boerhaave distilled pure mercury 500 times without perceiving any alteration in its boiling point. From these experiments he inferred that the given statements were erroneous. Geoffroy (1672-1731) published systematic tables of affinity, which exerted a long-continued influence on the science. Marggraf of Berlin (1709-'82) was distinguished as an analyst and technical chemist; he first called attention to the existence of sugar in the beet root and other plants indigenous to Europe. Macquer of Paris (1718-'84) pointed out the existence of arsenic acid, and made other new observations. His idea of four material elements, earth, air, fire, and water, illustrates the tendency of the period gradually to do away with the vague expressions of the alchemists. Equally characteristic is the fact that although Macquer had himself often used the quantitative method of analysis in investigating mineral waters and metallurgical matters, and considered it very necessary in such connection, he utterly neglected it when studying theoretical questions, and viewed with indifference the anti-phlogistic theory, founded on such unimportant data, as he thought, as mere differences of weight. He regarded phlogiston as identical with light, and capable of passing through transparent media, thus explaining the reduction of peroxide of mercury by heat, which had been observed in glass vessels. The English chemists of this period were, meanwhile, observing facts which afterward constituted the most effective weapons of the opponents of the phlogiston theory. The discoveries of Black, Cavendish, and Priestley led naturally to its overthrow. The investigation of the alkalies by Black of Edinburgh (1728 '99) was of great importance. It had previously been supposed that when limestone was burned it united with fire and thus obtained caustic properties. From caustic lime this fire could be transferred to the mild (carbonated) alkalies, rendering them caustic, while the lime having given up its fire became again mild. Black disproved this view by showing that the mild alkalies are compound bodies and become caustic, not by combining with fire, but from losing one of their constituents, a gas, which he called fixed air. He proved that limestone loses weight when burned to caustic lime, from which he inferred that the latter is contained in the former. He observed that the mild alkalies effervesce with acids, a gas similar to that given off by burning limestone being evolved. This gas (carbonic acid)
